| if(boolean condition, type ifTrue, type ifFalseOrNull) | Tests an expression and returns a corresponding result depending on whether the result is true, false, or NULL. | Same as ifTrue argument value |
| isfalse(), isnotfalse(), isnottrue(), istrue(), notnullvalue(), nullvalue() | These conditional functions provide enhanced compatibility when porting code that uses industry extensions. | |
| isnull(type a, type ifNotNull) | Tests if an expression is NULL, and returns the expression result value if not. If the first argument is NULL, returns the second argument. Equivalent to the nvl() function from Oracle Database or ifnull() from MySQL. | Same as the first argument value |

| | | |
|-----------------------------|--|--|
| nullif(expr1,expr2) | Returns NULL if the two specified arguments are equal. If the specified arguments are not equal, returns the value of expr1. The data types of the expressions must be compatible. You cannot use an expression that evaluates to NULL for expr1, so you can distinguish a return value of NULL from an argument value of NULL, which would never match expr2. | Same as the initial argument value, except that integer values are promoted to BIGINT and floating-point values are promoted to DOUBLE; use CAST() when inserting into a smaller numeric column |
| nullifzero(numeric_expr) | Returns NULL if the numeric expression evaluates to 0, otherwise returns the result of the expression. | Same as the initial argument value, except that integer values are promoted to BIGINT and floating-point values are promoted to DOUBLE; use CAST() when inserting into a smaller numeric column |
| nvl(type a, type ifNotNull) | Alias for the isnull() function; added in Impala 1.1. Tests if an expression is NULL, and returns the expression result value if not. If the first argument is NULL, returns the second argument. Equivalent to the nvl() function from Oracle Database or ifnull() from MySQL. | Same as the first argument value |
| zeroifnull(numeric_expr) | Returns 0 if the numeric expression evaluates to NULL, otherwise returns the result of the expression. | Same as the initial argument value, except that integer values are promoted to BIGINT and floating-point values are promoted to DOUBLE; use CAST() when inserting into a smaller numeric column |

Bit Manipulation Functions

Impala 2.5.0 introduces bit manipulation functions.

The following table lists the bit manipulation functions with their descriptions and return types:

| Function | Description | Return Type |
|-------------------------------------|---|-------------------------|
| bitand(integer_type a, same_type b) | Returns an integer value representing the bits that are set to 1 in both of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. The bitand() function is equivalent to the & binary operator. | Same as the input value |
| bitnot(integer_type a) | Inverts all the bits of the input argument. The bitnot() function is equivalent to the ~ unary operator. | Same as the input value |
| bitor(integer_type a, same_type b) | Returns an integer value representing the bits that are set to 1 in either of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. The bitor() function is equivalent to the binary operator. | Same as the input value |

| | | |
|--|--|-------------------------|
| bitxor(integer_type a, same_type b) | Returns an integer value representing the bits that are set to 1 in one but not both of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. The bitxor() function is equivalent to the ^ binary operator. | Same as the input value |
| countset(integer_type a [, int zero_or_one]) | By default, returns the number of 1 bits in the specified integer value. If the optional second argument is set to zero, it returns the number of 0 bits instead. | Same as the input value |
| getbit(integer_type a, int position) | Returns a 0 or 1 representing the bit at a specified position. The positions are numbered right to left, starting at zero. The position argument cannot be negative. When you use a literal input value, it is treated as an 8-bit, 16-bit, and so on value, the smallest type that is appropriate. The type of the input value limits the range of the positions. Cast the input value to the appropriate type if you need to ensure it is treated as a 64-bit, 32-bit, and so on value. | Same as the input value |
| rotateleft(integer_type a, int positions) | Rotates an integer value left by a specified number of bits. As the most significant bit is taken out of the original value, if it is a 1 bit, it is "rotated" back to the least significant bit. Therefore, the final value has the same number of 1 bits as the original value, just in different positions. Specifying a second argument of zero leaves the original value unchanged. Rotating a -1 value by any number of positions still returns -1, because the original value has all 1 bits and all the 1 bits are preserved during rotation. Similarly, rotating a 0 value by any number of positions still returns 0. Rotating a value by the same number of bits as in the value returns the same value. Because this is a circular operation, the number of positions is not limited to the number of bits in the input value. For example, rotating an 8-bit value by 1, 9, 17, and so on positions returns an identical result in each case. | Same as the input value |

| | | |
|---|--|--------------------------------|
| <p>rotateright(integer_type a, int positions)</p> | <p>Rotates an integer value right by a specified number of bits. As the least significant bit is taken out of the original value, if it is a 1 bit, it is "rotated" back to the most significant bit. Therefore, the final value has the same number of 1 bits as the original value, just in different positions. Specifying a second argument of zero leaves the original value unchanged. Rotating a -1 value by any number of positions still returns -1, because the original value has all 1 bits and all the 1 bits are preserved during rotation. Similarly, rotating a 0 value by any number of positions still returns 0. Rotating a value by the same number of bits as in the value returns the same value. Because this is a circular operation, the number of positions is not limited to the number of bits in the input value. For example, rotating an 8-bit value by 1, 9, 17, and so on positions returns an identical result in each case.</p> | <p>Same as the input value</p> |
| <p>setbit(integer_type a, int position [, int zero_or_one])</p> | <p>By default, changes a bit at a specified position to a 1, if it is not already. If the optional third argument is set to zero, the specified bit is set to 0 instead. If the bit at the specified position was already 1 (by default) or 0 (with a third argument of zero), the return value is the same as the first argument. The positions are numbered right to left, starting at zero. (Therefore, the return value could be different from the first argument even if the position argument is zero.) The position argument cannot be negative. When you use a literal input value, it is treated as an 8-bit, 16-bit, and so on value, the smallest type that is appropriate. The type of the input value limits the range of the positions. Cast the input value to the appropriate type if you need to ensure it is treated as a 64-bit, 32-bit, and so on value.</p> | <p>Same as the input value</p> |

| | | |
|---|--|-------------------------|
| shiftright(integer_type a, int positions) | Shifts an integer value right by a specified number of bits. As the least significant bit is taken out of the original value, it is discarded and the most significant bit becomes 0. In computer science terms, this operation is a "logical shift". Usage notes: Therefore, the final value has either the same number of 1 bits as the original value, or fewer. Shifting an 8-bit value by 8 positions, a 16-bit value by 16 positions, and so on produces a result of zero. Specifying a second argument of zero leaves the original value unchanged. Shifting any value by 0 returns the original value. Shifting any positive value right by 1 is the same as dividing it by 2. Negative values become positive when shifted right. | Same as the input value |
| shiftright(integer_type a, int positions) | Shifts an integer value left by a specified number of bits. As the most significant bit is taken out of the original value, it is discarded and the least significant bit becomes 0. The final value has either the same number of 1 bits as the original value, or fewer. Shifting an 8-bit value by 8 positions, a 16-bit value by 16 positions, and so on produces a result of zero. Specifying a second argument of zero leaves the original value unchanged. Shifting any value by 0 returns the original value. Shifting any value by 1 is the same as multiplying it by 2, as long as the value is small enough; larger values eventually become negative when shifted, as the sign bit is set. Starting with the value 1 and shifting it left by N positions gives the same result as 2 to the Nth power, or pow(2,N). | Same as the input value |

Analytic Functions

Analytic (window) functions operate on a set of rows and return a single value for each row from the underlying query. The term "window" describes the set of rows on which the function operates. A window function uses values from the rows in a window to calculate the returned values. When you use a window function in a query, you define the window using the OVER() clause. The OVER() clause (window clause) differentiates window functions from other analytical and reporting functions.

As of Impala 2.2.0, you can use the following analytic functions in queries:

- MAX()
- MIN()
- SUM()
- COUNT()

- AVG()
- RANK()
- LAG()
- LEAD()
- FIRST_VALUE()

As of Impala 2.5.0, you can use the following analytic functions in queries:

- PERCENT_RANK
- NTILE
- CUME_DIST

The analytic functions support the following syntax:

```
function(args) OVER([partition_by_clause] [order_by_clause] [window_clause])
partition_by_clause ::= PARTITION BY expr [, expr ...]
order_by_clause ::= ORDER BY expr [ASC | DESC] [NULLS FIRST | NULLS LAST] [, expr [ASC | DESC] [NULLS FIRST | NULLS LAST] ...]
```

The window clause supports the following syntax:

```
ROWS BETWEEN [ { m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT ROW | { UNBOUNDED | n } FOLLOWING] ]
```

```
RANGE BETWEEN [ {m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT ROW | { UNBOUNDED | n } FOLLOWING] ]
```

Miscellaneous Functions

The following table lists miscellaneous functions with their descriptions and syntax:

| Function | Description | Syntax |
|----------|--|----------------|
| uuid() | The uuid() function generates an alphanumeric value that you can use as a guaranteed unique identifier. The uniqueness applies across tables in cases where an ascending numeric sequence is not suitable. | select uuid(); |

Impala User-Defined Functions

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

A user-defined function (UDF) is a SQL function that you create to encapsulate code that processes column values during an Impala query. UDFs are called from within a SQL statement, like a regular function, and return a single value. Starting in Impala 1.2.3, you can create UDFs to perform custom calculations and transformations that built-in SQL operators and functions do not provide.

After you download and install the UDF development package, you can write your own UDFs and invoke them in the queries that you run on Impala. Impala can run scalar UDFs and UDAFs (user-defined aggregate functions).

Note: User-defined functions written in C++ persist when the catalog service is restarted. You no longer have to run the CREATE FUNCTION statements again after a restart. You must still reissue the CREATE FUNCTION statement for any Java-based user-defined functions.

UDFs and UDAFs

UDFs and UDAFs differ in the number of rows that they accept as input. A UDF operates on a single row and produces a single row as the output. When you use a UDF in a query, the UDF is called once for each row in the result set. Mathematical and string functions are examples of UDFs. When you create a UDF, you issue the CREATE FUNCTION statement. After you create a UDF, you can use it in the expression of a SQL statement.

A UDAF operates on multiple input rows and produces a single row as output. The COUNT(), MAX(), SUM(), and AVG() aggregate functions are examples of UDAFs. You might use a UDAF in a query with a GROUP BY clause to produce a result set with a separate aggregate value for each combination of values from the GROUP BY clause. When you create UDAFs, use the CREATE AGGREGATE FUNCTION statement. After you create a UDAF, you can use it the expression of a SQL statement.

When you create UDFs and UDAFs, they cannot have the same name as any of the built-in functions.

UDFs in C++ and Java

Impala accepts UDFs and UDAFs written in C++, as well as Hive UDFs written in Java. A Java UDF may cause a query in Impala to run much slower than the equivalent native UDF written in C++. If you use Hive UDFs when you query Impala, the Hive UDFs must meet the following conditions:

- Parameters and return values must all use data types that Impala accepts. Impala does not accept nested and composite types.
- UDFs cannot accept or return the TIMESTAMP data type.
- The return type must be a writable type, like Text or IntWritable. UDFs return a NULL value for Java primitive types, like string or int.
- Impala does not accept Hive UDAFs or UDTFs.

For more information about Hive UDFs, refer to the [Hive Language Manual UDF](#).

Get Started with UDFs

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Before you can write UDFs for your Impala queries, you must install the Impala development package that contains header and build configuration files and download the sample source code.

The development package provides a header file that is required to develop UDFs and UDAFs. The header contains the types that must be used and the FunctionContext object. This object is the interface object between the UDF or UDAF and the Impala process. You can access the header in `/usr/include/impala_udf/udf.h`

The sample source code provides sample files that you can view to see the declarations required to write UDFs and UDAFs, and sample source code used to create a simple UDF and UDAF example.

After you have installed the development package and sample source code, you can build the samples to create an environment that you can use to write your UDFs and UDAFs. Once you have completed your UDF or UDAF, you can deploy it.

Complete the following steps to create UDFs and UDAFs for use with Impala:

Install the Development Package

Use the appropriate commands for your operating system to install the development package.

To install the development package, complete the following steps:

1. Install the `gcc-c++` compiler and `boost-devel` using the command appropriate for your environment:

```
$ sudo yum install gcc-c++ cmake boost-devel
```

```
$ sudo apt-get install g++ libboost-devel cmake
```

2. Install the development package, using the command appropriate for your environment:

```
$ sudo yum install mapr-impala-udf
```

```
$ sudo apt-get install mapr-impala-udf
```

Warning: Impala is not required for UDF development. You can create UDFs on a minimal development system and then deploy the UDFs to a machine with Impala.

Download Sample Source Code

- To download the sample source code and build scripts, issue the following command:

```
git clone https://github.com/mapr/impala-udf-samples
```

The following table provides the source code file names and their descriptions:

| File Name | Description |
|---------------------------------|--|
| <code>udf-sample.h</code> | Header file that declares the signature for a scalar UDF. |
| <code>udf-sample.cc</code> | Sample source for a simple UDF that adds two integers. |
| <code>udf-sample-test.cc</code> | Basic unit tests for the sample UDF. |
| <code>uda-sample.h</code> | Header file that declares signature for sample aggregate functions. |
| <code>uda-sample.cc</code> | Sample source for simple UDAFs that show how to manage state transitions as underlying are called during various phases of query processing. |
| <code>uda-sample-test.cc</code> | Basic unit tests for the sample UDAFs. |

Build the Samples

To build the samples, complete the following steps:

1. Issue the `cmake` configuration command. This command reads the file `CMakeLists.txt`, and generates a `Makefile` customized for your directory paths.
2. Issue the `make` command. The `make` command runs the build steps based on rules in the `Makefile`. Impala loads the shared library from a filesystem location.

The samples get built to `build/`. This contains test executables that you can run locally, without the Impala service installed. It also contains shared object artifacts that you can run on Impala.

At this point, you can write your UDFs or UDAFs. When you write your functions, build a shared library to contain them. Use the `mapr` or `hadoop` commands to copy the binary files to a filesystem location that Impala can read from.

Writing UDFs

When you write UDFs, use function-oriented programming best practices, and note data type differences when transferring values from high-level SQL to low-level UDF code.

The UDF code samples that you downloaded include the `udf-sample.h` and `udf-sample.cc` files that you can reference when you write your UDFs. The `udf-sample.h` file provides the basic declarations required to write a scalar UDF. This file defines a simple function named `AddUdf()` that you can reference. The `udf-sample.cc` file provides sample C++ code for a simple function named `AddUdf()`.

Function Argument/Return Value Data Types

Every value that a UDF accepts as an argument or returns as a result, must map to a SQL data type that you can specify for a table column.

Every data type has a corresponding structure defined in the C++ and Java header files with two member fields and some predefined comparison operators and constructors:

- `is_null` indicates if a value is/is not NULL. When non-NULL, `val` holds the argument or return value.
- `null ()` is a member function that constructs an instance of the struct with the `is_null` flag set.
- `<`, `>=`, `BETWEEN`, `ORDER BY` are built-in SQL comparison operators and clauses that work automatically based on the SQL return type of each UDF.
- Every struct within your UDF code defines `==` and `!=` operators for comparisons with structs of the same type for typical C++ comparisons within your own code. Each kind of struct one or more constructors that define a filled-in instance of the struct.
- Every type of struct has a `null()` member function that returns an instance of the struct with `is_null` flag set.
- Impala cannot process UDFs that accept or return composite or nested types. This applies to UDFs written in C++ and Java-based Hive UDFs.
- You can create multiple functions with the same SQL name and different argument types to overload functions, however you must use different C++ or Java entry point names in the underlying functions.

The following table lists the data types defined for C++ in `/usr/include/impala_udf/udf.h`:

| Data Type | Description |
|--------------------------|---|
| <code>IntVal</code> | Represents an INT column. |
| <code>BigIntVal</code> | Represents a BIGINT column. |
| <code>SmallIntVal</code> | Represents a SMALLINT column. |
| <code>TinyIntVal</code> | Represents a TINYINT column. |
| <code>StingVal</code> | Represents a STRING column. It has a <code>len</code> field that represents the length of the string and a <code>ptr</code> field that points to the string data. It also has a constructor that creates a new <code>StingVal</code> struct based on a null-terminated C-style string or a pointer plus a length. It also has a constructor that takes a pointer to a <code>FunctionContext</code> struct and length, which does not allocate space for a new copy of the string data that you can use in UDFs that return string values. |
| <code>BooleanVal</code> | Represents a BOOLEAN column. |
| <code>FloatVal</code> | Represents a FLOAT column. |

| | |
|--------------|---|
| DoubleVal | Represents a DOUBLE column. |
| TimestampVal | Represents a TIMESTAMP column. It has a 32-bit integer date field that represents the Gregorian date and a 64-bit integer time_of_day field that represents the current time of day in nanoseconds. |

Variable-Length Argument List

Each argument is named explicitly in the signature of your C++ function. A UDF can take a fixed number of these named arguments, however a function can accept additional arguments if they are all of the same type.

You must code the signature of your function using the following format if you want your UDF to accept a variable-length argument list:

```
StringVal Concat(FunctionContext* context, const StringVal& separator, int num_var_args, const StringVal* args);
```

The SQL query call must pass at least one argument to the variable-length portion of the argument list. Impala calls the function and fills in the initial set of required arguments and then passes the extra arguments and a pointer to the first of the optional arguments.

NULL Values

Each UDF that you write must have the ability to handle NULL values. If a UDF receives a NULL value, it typically also returns a NULL value.

UDF Memory Allocation

Any memory allocated to a UDF is taken back by the system after the UDF exits. Input arguments remain allocated for the lifetime of a function. You can refer to the input arguments in expressions for return values. When using temporary variables to construct all new string values, use the `StringValue()` constructor, and copy the data into the newly allocated memory buffer. The `StringValue()` constructor takes an initial `FunctionContext*` argument followed by a length.

UDF Error Handling

Call functions that are members of the initial `FunctionContext*` argument passed to your function to handle UDF errors.

Use the following signature in the function to record warnings for conditions that indicate minor, recoverable problems that do not cause the query to stop:

```
bool AddWarning(const char* warning_msg);
```

Use the following signature if you want the UDF to set an error flag that prevents the query from returning any results in serious cases where the query cancellation must occur.

```
void SetError(const char* error_msg);
```

Writing UDAFs

A UDAF must maintain a state value across subsequent calls in order to accumulate a result across a set of calls, instead of deriving it purely from one set of arguments.

The underlying functions represent a UDAF:

Initialization function

Sets counters to zero, creates empty buffers, and performs any other initial setup for a query.

Update function

Processes the arguments for each row in the result set and accumulates an intermediate result for each node.

| | |
|--------------------------|---|
| Merge function | Combines the intermediate results from different nodes. |
| Finalize function | Passes through the combined result unchanged, or does one final transformation. |

Deploying UDFs and UDAFs

To deploy your UDFs or UDAFs, complete the following steps from the `impala-shell`:

1. Issue a `USE` statement to the database that you want to associate your new function with.
2. Issue a `CREATE FUNCTION` statement in the `impala-shell` to make Impala aware of the new function.
 - To deploy a UDF, issue the `CREATE FUNCTION` statement.
 - To deploy a UDAF, issue the `CREATE AGGREGATE FUNCTION` statement. Specify the entry points of the underlying C++ functions using the clauses `INIT_FN`, `UPDATE_FN`, and `FINALIZE_FN`.

Warning: You can also issue the `CREATE FUNCTION` with a fully qualified database name to skip the `USE` statement step. Example: `CREATE FUNCTION <db_name.function_name>`

Hive UDFs

To use Hive UDFs in Impala, get the applicable JAR files from the Hive UDFs, and use the Impala UDF deployment process to create new UDFs with new names.

Data types of arguments must match the function signature exactly when reusing Hive Java code for built-in functions.

To use a Hive UDF with Impala, complete the following steps:

1. Get a copy of the Hive JAR file with the UDFs that you want to use with Impala.
2. Issue the following command to see a list of classes inside the JAR file: `jar -tf <jar_filename>`
3. Copy the JAR file to a filesystem location that Impala can read.
4. From the `impala-shell`, create a database to use with the UDF.
5. To identify the data base that you want to query using the UDF, issue the `USE` statement to through the `impala-shell` for that particular database, or specify the SQL function name as `db_name.function_name`.
6. Issue a `CREATE FUNCTION` statement for each UDF that you want to use with Impala. The `CREATE FUNCTION` statement should contain a `LOCATION` clause with the full filesystem path to the JAR file and a `SYMBOL` clause with a fully qualified name of the class. Use dots as separators. Do not use the `.classpath` extension.
7. Issue a query and call the function. Pass the correct type of arguments to the function.

UDF Limitations

Impala UDFs have the following limitations:

- Impala cannot work with UDFs that accept or return composite, nested, or types not available in Impala tables.
- UDFs must produce the same output each time the same argument value is passed.
- UDFs cannot spawn other threads or processes.

- UDFs become undefined when you restart the catalogd process. In this scenario, you must reload the UDFs.
- You currently cannot include user-defined table functions in Impala queries.

UDF Security

If you enable the Impala authorization feature, consider the following:

- You must have the required read privilege for database and tables used in the query to call a UDF in the query.
- Only an administrative user can create UDFs because improperly coded UDFs can cause performance and capacity issues. Issuing the CREATE FUNCTION statement requires the ALL privilege on the server.

Supported SQL Language Features

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The Impala SQL dialect supports many standard SQL language features and some extensions for Hadoop related to data loading and data warehousing. The impala-shell interpreter supports multi-line commands. A semicolon at the end of each statement is required.

SQL Features

Impala supports the following SQL features:

- Comments
- External/Internal tables
- Hints
- Joins
- Views

Statements

Impala supports the following SQL statements:

- ALTER TABLE
- CASCADE
- CREATE DATABASE
- CREATE TABLE
- CREATE TABLE AS SELECT
- CREATE VIEW
- DESCRIBE
- DROP DATABASE
- DROP TABLE/ALTER TABLE DROP PARTITION
- EXPLAIN

- INSERT
- INVALIDATE METADATA
- LOAD DATA
- PURGE
- REFRESH
- SELECT
- SHOW
- SHOW DATABASES
- TRUNCATE TABLE
- USE

Clauses

Impala supports the following SQL clauses:

- IF EXISTS
- WHRRE
- VALUES
- WITH
- GROUP BY
- HAVING
- LIMIT
- ORDER BY

Operators

Impala supports the following SQL operators:

- BETWEEN
- DISTINCT
- ILIKE
- IREGEXPR
- IS [NOT] DISTINCT FROM
- LIKE
- REGEXP
- RLIKE

Functions

Impala supports the following SQL functions:

- AVG
- BITAND
- BITNOT
- BITOR
- BITXOR
- BTRIM
- CHR
- COT
- COUNT
- COUNTSET
- CUME_DIST
- DCEIL
- DEXP
- DFLOOR
- DLOG10
- DPOW
- DROUND
- DSQRT
- DTRUNC
- FACTORIAL
- FPOW
- GETBIT
- GROUP_CONCAT
- INT_MONTHS_BETWEEN
- MAX
- MIN
- MONTHS_BETWEEN
- NDV
- NTILE

- PERCENT_RANK
- REGEXP_LIKE
- ROTATELEFT
- ROTATERIGHT
- SETBIT
- SHIFLEFT
- SHIFTRIGHT
- SPLIT_PART
- SUM
- TIMEOFDAY
- TIMESTAMP_CMP
- TYPEOF

Data Types

Impala supports the following SQL data types:

- BIGINT
- BOOLEAN
- DECIMAL
- DOUBLE
- FLOAT
- INT
- SMALLINT
- NULL
- STRING
- TIMESTAMP
- TINYINT

Impala supports the following complex data types:

- STRUCT
- ARRAY
- MAP

Supported and Unsupported SQL/HiveQL Language Features

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Supported HiveQL Statements and Clauses

- JOIN
- AGGREGATE
- DISTINCT
- UNION ALL
- ORDER BY (Must use a LIMIT clause with ORDER BY.)
- LIMIT (Accepts arithmetic expressions and numeric literals. You can include the OFFSET clause with the LIMIT clause to produce paged result sets, like 11-20.)
- FROM (You can include FROM in an uncorrelated subquery.)
- INSERT INTO
- INSERT OVERWRITE
- LEFT|RIGHT ANTI JOIN

Supported SQL Statements

When you issue an SQL statement, use a semicolon at the end of each statement.

- COMPUTE INCREMENTAL STATS
- COMPUTE STATS
- CREATE ROLE
- CREATE TABLE
 - Use the STORED AS PARQUET or STORED AS TEXTFILE clause with CREATE TABLE to identify the format of the underlying data files.
 - Use the TBLPROPERTIES clause with CREATE TABLE to associate random metadata with a table as key-value pairs.
 - Use SERDEPROPERTIES with CREATE TABLE to set up metadata that defines how tables are read and written. This may be required for Hive compatibility.
 - USE WITH SERDEPROPERTIES with CREATE TABLE to specify the SerDe classes that read and write data for a table. This may be required for Hive compatibility.
- CREATE TABLE AS SELECT
- CREATE VIEW
- CURRENT DATABASE(Returns the database that the session is currently using.)
- DESCRIBE
- DROP INCREMENTAL STATS
- DROP ROLE
- EXPLAIN (You can issue the command SET EXPLAIN_LEVEL=verbose for more detailed EXPLAIN output. To revert, issue the command SET EXPLAIN_LEVEL=normal.)

- EXPLAIN PLAN
- GRANT
- INVALIDATE METADATA
- LOAD DATA
- REFRESH
- REVOKE
- SELECT
 - You can use the STRAIGHT_JOIN keyword immediately after SELECT to override the reordering of join clauses that Impala does internally.
- SHOW CREATE TABLE
- SHOW DATABASES
- SHOW FILES
- SHOW FUNCTIONS
- SHOW GRANT ROLE
- SHOW ROLE GRANT GROUP
- SHOW ROLES
- SHOW SCHEMAS
- SHOW TABLES
- SHOW COLUMN STATS
- SHOW TABLE STATS
- USE

Supported DDL Statements

DDL statements typically change the table schema. Issue an INVALIDATE METADATA statement manually on the other nodes to update metadata. You can use the SET command to enable the SYNC_DDL option with any DDL statements to return after the Impala catalog service has propagated changes on all Impala nodes.

- ALTER TABLE
 - Use the TBLPROPERTIES clause with ALTER TABLE to associate random metadata with a table as key-value pairs.
 - Use SERDEPROPERTIES with ALTER TABLE to set up metadata that defines how tables are read and written. This may be required for Hive compatibility.
- ALTER VIEW
- COMPUTE STATS
- CREATE DATABASE

- CREATE FUNCTION
- CREATE ROLE
- CREATE TABLE
- CREATE VIEW
- DROP DATABASE
- DROP FUNCTION
- DROP ROLE
- DROP TABLE
- DROP VIEW
- GRANT
- REVOKE

Supported DML Statements

Impala only supports the INSERT and LOAD DATA statements which modify data stored in tables.

- Issue the REFRESH statement on other nodes to refresh the data location cache.
- If the SYNC_DDL statement is enabled, INSERT statements complete after the catalog service propagates data and metadata changes to all Impala nodes.
- You can use the [SHUFFLE] and [NOSHUFFLE] hints with INSERT to redistribute work during INSERT...SELECT operations. You may want to use these hints when inserting into partitioned Parquet tables to avoid memory consumption problems and simultaneous open files, by collecting new data for each partition on a specific node.

Supported Datatypes

Impala supports datatypes with the same names and semantics equivalent to those in Hive.

- char
- varchar
- complex
- string
- tinyint
- smallint
- int
- bigint
- float
- double
- boolean

- string
- timestamp
- asSTRING

Supported Operators

SQL operators are a class of comparison functions used within the WHERE clauses of a SELECT statement.

- BETWEEN
- COMPARISON
- CROSS JOIN (Use as the join operator for Cartesian joins; does not use any ON clause.)
- IN
- IS NULL
- LIKE
- [NOT] EXISTS
- [NOT] IN
- REGEXP
- RLIKE

Supported Literals

Each of the Impala data types has corresponding notation for literal values of that type. Specify literal values in SQL statements, such as in the SELECT list or WHERE clause of a query, or as an argument to a function call.

- Numeric
- String
- Boolean
- Timestamp
- NULL (You can add the NULLS FIRST or NULLS LAST clause at the end of the ORDER BY clause to override or specify the sorting behavior for NULL.)

Supported Schema Objects and Object Names

- Aliases
- Identifiers
- Databases
- Tables
- Views
- Functions

Analytic Functions

Analytic (window) functions operate on a set of rows and return a single value for each row from the underlying query. The term "window" describes the set of rows on which the function operates. A window function uses values from the rows in a window to calculate the returned values. When you use a window function in a query, you define the window using the OVER() clause. The OVER() clause (window clause) differentiates window functions from other analytical and reporting functions.

As of Impala 2.2.0, you can use the following analytic functions in queries:

- MAX()
- MIN()
- COUNT()
- AVG()
- RANK()
- LAG()
- LEAD()
- FIRST_VALUE()
- MAX(), SUM()
- COUNT()

The analytic functions support the following syntax:

```
function(args) OVER([partition_by_clause] [order_by_clause] [window_clause])
partition_by_clause ::= PARTITION BY expr [, expr ...]
order_by_clause ::= ORDER BY expr [ASC | DESC] [NULLS FIRST | NULLS LAST] [, expr
[ASC | DESC] [NULLS FIRST | NULLS LAST] ...]
```

The window clause supports the following syntax:

```
ROWS BETWEEN [ { m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT ROW |
{ UNBOUNDED | n } FOLLOWING] ]
RANGE BETWEEN [ {m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT ROW |
{ UNBOUNDED | n } FOLLOWING] ]
```

Supported Aggregate Functions

Aggregate functions calculate a return value across all the items in a result set. When you issues a function, you must include a FROM clause in the query. Aggregate functions ignore NULL values rather than returning a NULL result.

- APPX_MEDIAN()
- AVG()
- COUNT()
- GROUP_CONCAT()
- MAX()
- MIN()
- NDV()

- SUM()

Built-in Functions

Impala supports lots of built-in functions that you can use directly with a SELECT statement to perform data transformation operations, such as mathematical calculations, string manipulations, and data calculations.

Unsupported SQL Features

- Non-scalar data types, such as maps, arrays, structs
- LOAD DATA to load raw files
- Restricted set of literal formats for the TIMESTAMP data type and the from_unixtime() format string
- Extensibility mechanisms such as TRANSFORM, custom file formats, or custom SerDes
- XML and JSON functions
- The following HiveQL aggregate functions: variance, var_pop, var_samp, stddev_pop, stddev_samp, covar_pop, covar_samp, corr, percentile, percentile_approx, histogram_numeric, collect_set
- User Defined Table Generating Functions (UDTFs)
- User Defined Aggregate Functions (UDAFs)
- User Defined Functions
- Sampling
- Lateral views
- Authorization features such as roles
- Multiple DISTINCT clauses per query

Unsupported HiveQL Statements

- ANALYZE TABLE (the Impala equivalent is COMPUTE STATS)
- DESCRIBE COLUMN
- DESCRIBE DATABASE
- EXPORT TABLE
- IMPORT TABLE
- SHOW PARTITIONS
- SHOW TABLE EXTENDED
- SHOW TBLPROPERTIES
- SHOW FUNCTIONS
- SHOW COLUMNS
- SHOW CREATE TABLE
- SHOW INDEXES

Semantic Differences in Impala Statements vs HiveQL

- Different syntax and names for query hints.
- MapReduce specific features of SORT BY, DISTRIBUTE BY, or CLUSTER BY are not exposed.
- Queries do not need a FROM clause.
- Impala does not allow:
 - Implicit cast between string and numeric or Boolean types
 - Implicit casts among the numeric types or from string to timestamp
 - Storing timestamps using the local timezone; Timestamps are stored relative to GMT
 - Return column overflows as NULL; Impala returns the largest or smallest value in the range for the type
 - Virtual columns
- Impala does not:
 - Expose locking
 - Expose some configuration properties

Impala Limitations

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

What Impala Does Not Provide

Impala does not replace Hive or other frameworks built on MapReduce for long-running batch-oriented queries.

Impala is not fit as a query layer to support operational/OLTP applications (No update/deletes, not optimized for point look-ups).

Known Limitations in Impala

Impala has the following known limitations:

- The LOAD DATA statement does not work when the source directory and destination table are in different encryption zones.
- The Impala configuration option, `--disk_spill_encryption`, is not supported to secure sensitive data from being observed or tampered with when temporarily stored on disk.
- Redaction of sensitive data from Impala log files is not supported.
- You cannot use the lineage information feature to track who has accessed data through Impala SQL statements.

Impala UDFs (user-defined functions) have the following known limitations:

- Impala does not work with UDFs that accept or return composite, nested, or types not available in Impala tables.
- UDFs must produce the same output each time the same argument value is passed.

- UDFs cannot spawn other threads or processes.
- Prior to Impala 2.5.0, UDFs become undefined when you restart the catalog service. You must reload the UDFs.
- You currently cannot include user-defined table functions in Impala queries.

Impala Security

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Features

-  **Warning:** While Impala is compatible with the platform, using Impala security is not encouraged for several reasons:
- By design, Impala security secures data outside the underlying filesystem, which creates the potential of backdoor access. When you enable Impala authorization using Sentry, the platform security is bypassed and the HPE Ezmeral Data Fabric can no longer fully secure your data.
 - If you enable this Impala security, impersonation will be disabled and data ownership will be shifted to the Impala user, which makes the "Impala" data inaccessible by regular users through means other than Hive or Impala (because the users no longer own the data).

You can configure Impala to use the security features listed in the next table on either a secure or a non-secure cluster. If you use the Installer and select **Enable Secure Cluster**, Impala will not be automatically secured.

| Feature | Description |
|----------------------------------|---|
| LDAP | You can configure LDAP authentication for client connections with Impala. You can use LDAP authentication with Sentry to authenticate users and provide precise levels of access to users. See LDAP Authentication for Impala . |
| Kerberos | You can configure Impala to use Kerberos for authentication. You can also use Sentry authorization in conjunction with Kerberos if you want to configure user-level access to databases, tables, columns, and partitions. See Enable Kerberos Authentication for Impala . |
| HPE Ezmeral Data Fabric Security | You can configure security between Impala and Hive. See Configure Hive Metastore to use MapR-SASL on page 3649.  Note: Default security is not present between the Impala client and the Impala server. To avoid security holes, you must configure the Impala client on Kerberos or LDAP. |
| SSL | You can enable SSL network encryption for communication between Impala and client programs and between Impala nodes in a cluster. See Enable SSL for Impala . |

Important: The Impala client does not support HPE Ezmeral Data Fabric ticket security, but you can authentication connections as follows:

- Between the Impala server and client (JDBC, Impala-shell) - Kerberos or LDAP. However, you might encounter issues with Impala on Kerberos using the JDBC connector.
- Between Impala (the Impala catalog) and Hive metastore - HPE Ezmeral Data Fabric ticket security or Kerberos.

To avoid security holes, configure Impala on Kerberos or LDAP. If Impala is not secure or only has LDAP authentication enabled, only the client connection to Impala is authenticated and there is no wire level encryption or server-to-server authentication.

You can enable [MapR SASL for the Hive metastore](#). When the Hive metastore is SASL enabled, Impala can run in any security mode (none, LDAP, or Kerberos).

Component Compatibility

You can configure Impala to use the components and/or features listed below on a secure cluster. The following table assumes that each component is configured with Kerberos on Impala. Hive and Hue can be configured with security for authentication.

Note: HPE Ezmeral Data Fabric security is not present between the Impala client and the Impala server. To avoid security holes, you must configure the Impala client on Kerberos or LDAP. Hive and Hue use HPE Ezmeral Data Fabric security.

| Component | Version | Impala 1.4.1 | Impala 2.2.0 | Impala 2.5.0 | Impala 2.7.0 | Impala 2.10 |
|-----------|-----------------|--------------|--------------|--------------|--------------|-------------|
| Core | 6.0.x and later | Yes | Yes | Yes | Yes | Yes |
| | 5.1.x and later | Yes | Yes | Yes | Yes | Yes |
| | 5.0.x | Yes | Yes | No | No | No |
| | 4.0.1 | Yes | No | No | No | No |
| LDAP | N/A | Yes | Yes | Yes | Yes | Yes |
| Kerberos | N/A | Yes | Yes | Yes | Yes | Yes |
| Sentry | 1.7 | No | No | No | Yes | Yes |
| | 1.6 | No | Yes | Yes | No | No |
| Hue | 4.2 | No | No | No | No | Yes |
| | 3.12 | No | No | No | Yes | Yes |
| | 3.9 | Yes | Yes | Yes | No | No |
| | 3.6 | Yes | No | No | No | No |
| | 1.4 | Yes | No | No | No | No |
| Hive | 2.3 | No | No | No | No | Yes |
| | 2.1.x | No | No | No | Yes | Yes |
| | 1.2.1 | No | Yes | Yes | No | No |
| | 0.13 | Yes | No | No | No | No |

The following table lists the supported and unsupported component and security combinations necessary to access the Hive metastore:

| Impala Client Security Mode | Hive + MapR SASL | Hive + Kerberos |
|-----------------------------|--|---------------------------------|
| |  Note: The Impala Catalog will access Hive Metastore using the default security. | |
| None | Supported | Not supported |
| LDAP | Supported | Not supported |
| Kerberos | Supported  Note: Issues with JDBC might exist. | Supported |

Related concepts

[Using the Enable Secure Cluster Option](#) on page 5630

You use the Enable Secure Cluster option to control whether or not the cluster is configured as a secure cluster.

Enable Kerberos Authentication

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

You can enable Kerberos authentication for Impala on a secure and non-secure cluster.

Once you have configured Impala to use Kerberos for authentication, restart Impala and then start the `impala-shell` with the `-s mapr -k` flags to enable Kerberos.

To enable Kerberos authentication for Impala, complete the following steps:

1. Enable encryption between RPC services on Kerberos in `core-site.xml` (change "hadoop.rpc.protection" value to "privacy") and copy `core-site.xml` to Impala-conf directory:

```
<property>
  <name>hadoop.rpc.protection</name>
  <value>privacy</value>
</property>
```

And restart the Warden service to apply changes in `core-site.xml`.

2. Copy the following files to the `$IMPALA_HOME/conf/` directory:

- `$HIVE_HOME/conf/hive-site.xml`

- `$HADOOP_HOME/etc/hadoop/core-site.xml`

Note: Any time the `hive-site.xml` file is modified, copy the file to the `$IMPALA_HOME/conf/` directory.

3. Create service principals for each host that runs `impalad`, `catalogd`, or `statedored` and for the HTTP service. Principal names take the following form:

```
mapr/<fully.qualified.domain.name>@<KERBEROS.REALM>
```

- a. Create an Impala service principal and specify the following information:
 - Name "mapr"

- Fully qualified domain name of each node running impalad
- Realm name

```
kadmin: addprinc -requires_preauth -randkey -allow_renewable mapr/
impala_host.example.com@TEST.EXAMPLE.COM
```

- b.** Create an HTTP service principal.

```
kadmin: addprinc -randkey HTTP/
impala_host.example.com@TEST.EXAMPLE.COM
```

4. Create, merge, and distribute keytab files for the principals.

- a.** Create keytab files with both principals.

```
kadmin: xst -k /opt/mapr/conf/mapr.keytab mapr/impala_host.example.com
```

- b.** Use the keytab utility to read the content of the keytab files and then write the content to a new file.

```
ktutil
ktutil: rkt /opt/mapr/conf/mapr.keytab
ktutil: rkt /opt/mapr/conf/http.keytab
ktutil: wkt /opt/mapr/conf/mapr-http.keytab
ktutil: quit
```

- c.** Optionally, test the credentials in the merged keytab file to verify their validity and to verify that “renew until” data is set to a future time.

```
klist -e -k -t /opt/mapr/conf/mapr-http.keytab
```

- d.** Change the file owner to the `mapr` user to make `mapr` the only user authorized to read the file content.

```
chmod 400 /opt/mapr/conf/mapr-http.keytab
```

5. Edit `/opt/mapr/impala/impala-<version>/conf/env.sh` to include the fully qualified domain name for the `IMPALA_STATE_STORE_HOST`, `IMPALA_STATE_STORE_HOST` variables, and Kerberos options.

- a.** Set the `IMPALA_STATE_STORE_HOST` and `CATALOG_SERVICE_HOST` variables to point to the fully qualified domain name.

```
IMPALA_STATE_STORE_HOST=impala_host.example.com
IMPALA_STATE_STORE_PORT=24000
CATALOG_SERVICE_HOST=impala_host.example.com
```

- b. Add the following Kerberos options for `impalad`, `catalogd`, and `statedstore` daemons using the `IMPALA_SERVER_ARGS`, `IMPALA_CATALOG_ARGS`, and `IMPALA_STATE_STORE_ARGS` variables:

```
-kerberos_reinit_interval=60
-principal=mapr/impala_host.example.com@TEST.EXAMPLE.COM
-keytab_file=/opt/mapr/conf/mapr-http.keytab
```

```
IMPALA_SERVER_ARGS=" \
  -log_dir=${IMPALA_LOG_DIR} \
  -state_store_port=${IMPALA_STATE_STORE_PORT} \
  -use_statestore \
  -authorized_proxy_user_config=mapr=* \
  -state_store_host=${IMPALA_STATE_STORE_HOST} \
  -catalog_service_host=${CATALOG_SERVICE_HOST} \
  -be_port=${IMPALA_BACKEND_PORT} \
  -disable_admission_control=true \
  -kerberos_reinit_interval=60 \
  -principal=mapr/impala_host.example.com@TEST.EXAMPLE.COM \
  -keytab_file=/opt/mapr/conf/mapr-http.keytab "
```

- c. Restart Impala and the catalog and statestore services. See [Managing Impala](#).
- d. To enable Kerberos from the `impala-shell`, start the `impala-shell` with the `-s mapr -k` flags.

```
impala-shell -s mapr -k
```

For more information on changing the Impala defaults specified in `env.sh`, see [Impala-Shell Commands](#).

Enable SSL for Impala

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Impala 2.5.0 supports SSL encryption for internal Impala connections.

Complete the following steps to configure SSL for Impala:

1. Configure encryption in Hive. See [Hive Encryption](#).
2. Configure client-server encryption only or configure client-server and Impala internal encryption.
 - To configure client-server encryption only, add the following start-up options for the Impala Server to `/opt/mapr/impala/impala-<version>/conf/env.sh`:

```
-ssl_server_certificate          Full path to the server certificate on the local
                                filesystem.
```

```
-ssl_private_key                Full path to the server private key on the local
                                filesystem.
```

- To configure client-server and Impala internal encryption, add the following start-up options for the Impala server, catalog, and statestore to `/opt/mapr/impala/impala-<version>/conf/env.sh`:

```
-ssl_server_certificate          Full path to the server certificate on the local
                                filesystem.
```

```
-ssl_private_key                Full path to the server private key on the local
                                filesystem.
```

`--ssl_client_ca_certificate`

Full path to the certificate on the local filesystem required for client/server encryption.

Note: When you add the SSL flags to Impala start-up options, Impala listens for HiveServer2 on the SSL-secured ports. A client program usually has equivalent options to verify a connection to the correct server.

After you enable SSL, you can issue the following options when you start the `impala-shell`:

| Option | Description |
|------------------------|---|
| <code>--ssl</code> | Enables SSL for the <code>impala-shell</code> . |
| <code>--ca_cert</code> | Local path name that points to the third-party CA certificate, or to a copy of the server certificate for self-signed server certificates. If <code>--ca_cert</code> is not set, <code>impala-shell</code> enables SSL, but does not validate the server certificate. This is useful for connecting to an Impala node that you know is only running over SSL when a copy of the certificate is not available. |

For more information about the `impala-shell`, refer to [Impala-Shell Commands](#).

For more information about configuring Impala start-up options, see [Additional Impala Configuration Options](#).

LDAP Authentication

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

As of Impala 1.2.3, client connections with Impala can be authenticated against LDAP servers. You can configure LDAP authentication for client connections with Impala on a non-secure cluster. When you configure LDAP authentication, you must configure SSL between the client and Impala, and between Impala and the LDAP server to avoid sending credentials over the wire in clear text. Configuration requirements apply to the server side when configuring and starting Impala.

If the Hive metastore has `data-fabric-SASL` enabled, copy `$HIVE_HOME/conf/hive-site.xml` to `$IMPALA_HOME/conf/`. Repeat this step any time the `hive-site.xml` file is modified.

Modify `/opt/mapr/impala/impala-<version>/conf/env.sh` and include the following options to configure Impala server LDAP authentication:

| Options | Description |
|--|---|
| <code>--enable_ldap_auth</code> | Set this option to "true" in all environments to enable LDAP authentication between Impala and the client. |
| <code>--ldap_uri</code> | Sets the URI of the LDAP server to use. Typically, the URI is prefixed with <code>ldap://<hostname></code> . Optionally, the URI can specify the port. For example, <code>ldap://<hostname>:<port></code> . |
| <code>--ldap_manual_config extend col</code> | Bypasses all of the automatic configuration if you need to provide a custom SASL. |
| <code>--ldap_tls</code> | Tells Impala to start a TLS connection to the LDAP server and to fail authentication if Impala cannot start the TLS connection. |

Example:

```
IMPALA_SERVER_ARGS=" \
  -log_dir=${IMPALA_LOG_DIR} \
  -state_store_port=${IMPALA_STATE_STORE_PORT} \
  -enable_ldap_auth=true \
  -ldap_uri=ldap://10.250.1.5/ \
  -ldap_tls=true \
  -use_statestore \
  -state_store_host=${IMPALA_STATE_STORE_HOST} \
  -catalog_service_host=${CATALOG_SERVICE_HOST} \
  -be_port=${IMPALA_BACKEND_PORT}"
```

After you restart the Impala server, statestore, and catalog, you can connect to Impala using LDAP authentication. To connect to Impala, launch the `impala-shell` from a client node and issue the following commands:

| Command | Description |
|----------------------------------|--|
| <code>-l</code> | Enables LDAP authentication. |
| <code>-u</code> | Sets the user. The <code>impala-shell</code> prompts you for the password. Per Active Directory, the user is the short username, not the full LDAP distinguished name. |
| <code>--ldap_password_cmd</code> | (Impala 2.5.0 only) Sets the bash command to retrieve the LDAP user password. |

Example:

```
impala-shell -l -u
uid=qa-user1,ou=People,dc=maprtech,dc=com --ldap_password_cmd="echo -n
secret"
```

Sentry

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Important: Sentry is only supported with Impala, Hive, and Hue if you purchase Impala support and configure Impala to use Sentry.

Apache Sentry is an authorization module for Hadoop that provides the granular, role-based authorization required to provide precise levels of access to authenticated users and applications. Sentry allows users to see only those objects for which they have privileges.

Storage Models

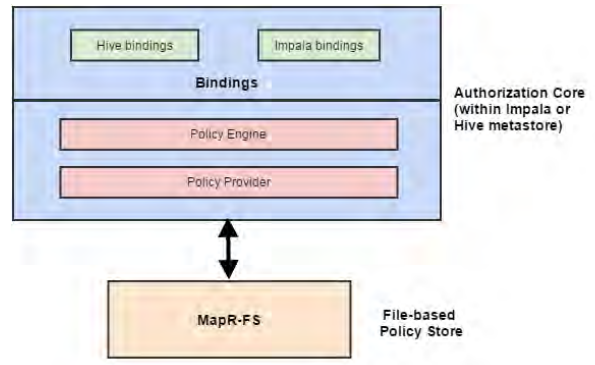

Sentry supports two models for storing policy rules:

Database storage (preferred)

As of Sentry 1.6-1602, you can configure Sentry to use the database storage mode. With this mode, the Sentry service provides access to read and maintain privileges and roles from a database.

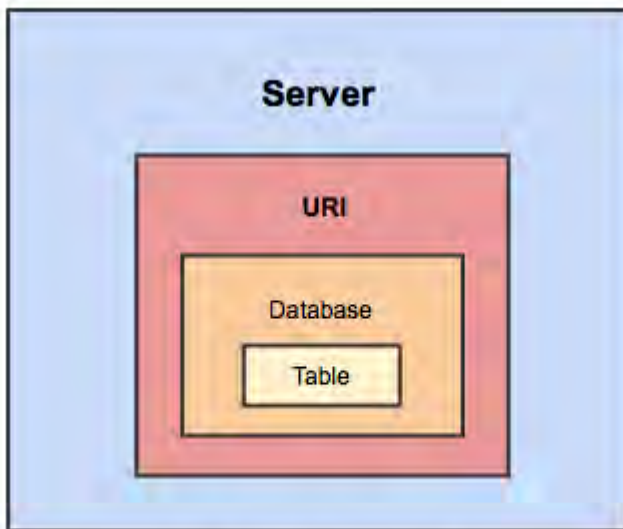

File-based storage

Privileges and roles are accessed from and maintained in a policy file (`global-policy.ini`) which you can store on the filesystem. The following diagram illustrates the architecture of the file-based storage model:

Privileges

Privileges are granted on different objects in the schema, including tables, databases, URIs and servers. The object hierarchy is set up like this, where objects inherit privileges from objects above them in the hierarchy:

Object Hierarchy

Privileges and roles are specified in either a relational database (for database rule storage) or a `global-policy.ini` file (for file-based rule storage). The following examples show a `global-policy.ini` file along with the equivalent set of privileges and roles expressed in HiveSQL syntax.

Sample `global-policy.ini` File

```
[groups]
# Assigns each Hadoop group to its set of roles
manager = analyst_role, junior_analyst_role
analyst = analyst_role
jranalyst = junior_analyst_role
customers_admin = customers_admin_role
admin = admin_role

[roles]
```

```
# The uris below define a landing pad which
# the user can use to import or export data from the system.
# Since the server runs as the user "hive," files in that directory
# must either have read/write permissions set for the group hive
# or have read/write permissions set for world.
analyst_role = server=HS2->db=analyst1, \
server=HS2->db=jranalyst1->table=*>action=select
server=HS2->uri=maprfs:/landing/analyst1
junior_analyst_role = server=HS2->db=jranalyst1, \
server=HS2->uri=maprfs:/landing/jranalyst1

# Implies everything on HS2.
admin_role = server=HS2
```

Known Issues

Upgrading Sentry

If you are upgrading from Sentry in EEP 6.3.1 or EEP 7.0.0 to Sentry in the latest EEP version, manually back up the `/conf` and `/logs` directories located in `SENTRY_HOME`. After the upgrade completes, add those directories back into the `SENTRY_HOME` directory.

You can see the `/conf` and `/logs` directories listed in the Sentry installation directory, as shown:

```
ll /opt/mapr/sentry/sentry-1.7.0
total 76
drwxr-xr-x 2 mapr mapr 4096 Jan 5
13:34 bin
-rw-r--r-- 1 mapr mapr 15211 Jan 5
10:26 CHANGELOG.txt
drwxr-xr-x 2 mapr mapr 4096 Jan 5
13:34 conf
drwxr-xr-x 2 mapr mapr 4096 Jan 5
13:34 conf.d

```

See [Pre-Upgrade Steps for Sentry](#) on page 298 and [Upgrading Sentry](#) on page 321.

Removing Sentry

This issue applies to Sentry in EEP 6.3.1 and EEP 7.0.0.

If you try to remove Sentry on an Ubuntu OS before the Sentry process has started (the Sentry process

does not exist), the system may return the following error message:

```
...
dpkg: error processing package
mapr-sentry (--purge):
 subprocess installed pre-removal
script returned error exit status 1
Errors were encountered while
processing:
 mapr-sentry
E: Sub-process /usr/bin/dpkg returned
an error code (1)
...
```

As a workaround, to completely remove Sentry on an Ubuntu OS, run:

```
sudo mv /var/lib/dpkg/info/
mapr-sentry.* /tmp/
sudo
dpkg --remove --force-remove-reinstreq
mapr-sentry
sudo rm -rf /opt/mapr/sentry/
```

Sentry Feature Support

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

 **Important:** Support for Sentry is limited to Impala users.

- HDFS ACLs are not supported.
- As of Sentry 1.6-1602, the database storage mode is supported. It was not supported in the Sentry 1.4.0-1412 release.
- Sentry 1.7.0-1703 supports Sentry Simple Shell and Hive Authorization V2.

The global-policy.ini File

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The default `global-policy.ini` file defines the `admin_role`, which gives full access to the Hiveserver2 server for the `mapr` user. The file is located in `/opt/mapr/sentry/sentry-<version>/conf` in your local file system. You can relocate the file to the filesystem if you prefer. By default, the file contains these sections:

```
[groups]
mapr = admin_role

[roles]
admin_role = server=HS2
```

Sample sentry-provider.ini File

```
[databases]
# Defines the location of the per-DB policy file for the customer's
```

```
DB or schema
customers = /etc/sentry/customers.ini

[groups]
customers_admin = customers_admin_role

[roles]
customers_admin_role = server=HS2->db=customers
```

Sample customers.ini File

```
[groups]
manager = customers_insert_role, customers_select_role
analyst = customers_select_role

[roles]
customers_insert_role =
server=HS2->db=customers->table=*->action=insert
customers_select_role =
server=HS2->db=customers->table=*->action=select
```

Configuring Sentry

The steps to configure Sentry are determined by the storage model, the type of security used by the cluster, and the components that will use Sentry authorization.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

1. Configure Sentry to use one of the following storage models: file-based storage or database storage.
2. If the cluster is secure, you can configure Sentry to use kerberos authentication.
3. Based on your requirements, complete the steps to integrate Sentry with one or more ecosystem components.

Configure Sentry to use Database Storage

As of Sentry 1.6, the database storage model is the preferred method for storing privileges and roles. When you configure Sentry to use the database storage model, it also includes a service that is managed by Warden.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The following databases can be used to store privileges and roles: MySQL, Oracle, Postgres, DB2 and Derby. Examples in the following procedure use MySQL as the database type.

 **Note:** When you install Sentry with the Installer and you specify MySQL as the database for Sentry, the Installer performs the following configurations.

1. Create a database for Sentry.

For example, run the following commands to create a MySQL database:

```
mysql> create database sentry_store;
mysql> use sentry_store;
mysql> create user 'sentry'@'<hostname>' identified by 'sentry';
mysql> grant all on *.* to 'sentry'@'<hostname>' identified by 'sentry';
mysql> flush privileges;
```

- In `/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`, update the value of the following property:

| Property | Configuration |
|---|---|
| <code>sentry.hive.provider.backend</code> | Set the value to <code>org.apache.sentry.provider.db.SimpleDBProviderBackend</code> |

For example:

```
<property>
  <name>sentry.hive.provider.backend</name>
  <value>org.apache.sentry.provider.db.SimpleDBProviderBackend</value>
  <description> Options:
  {org.apache.sentry.provider.db.SimpleDBProviderBackend,
  org.apache.sentry.provider.file.SimpleFileProviderBackend}Privilege
  provider to be used, we support file based or db based</description>
</property>
```

- In the `sentry-site.xml` file (`/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`), add the following properties:

| Property | Configuration |
|---|---|
| <code>sentry.store.jdbc.url</code> | Set the value to the JDBC connection URL. |
| <code>sentry.store.jdbc.driver</code> | Set the value to the Backend JDBC driver. |
| <code>sentry.store.jdbc.user</code> | Set the value to the JDBC user name. |
| <code>sentry.store.jdbc.password</code> | Set the value to the JDBC password. |

For example:

```
<property>
  <name>sentry.store.jdbc.url</name>
  <value>jdbc:mysql://localhost/sentry_store</value>
</property>

<property>
  <name>sentry.store.jdbc.driver</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>sentry.store.jdbc.user</name>
  <value>sentry</value>
</property>

<property>
  <name>sentry.store.jdbc.password</name>
  <value>sentry</value>
</property>
```

- Initialize the database schema.

```
/opt/mapr/sentry/sentry-<version>/bin/sentry --command
schema-tool --confdir /opt/mapr/sentry/sentry-<version>/conf/
sentry-site.xml --dbType mysql --initSchema
```

- To add Sentry to the list of services that Warden monitors, copy `/opt/mapr/sentry/sentry-<version>/conf.d/warden.sentry.conf` to `/opt/mapr/conf/conf.d`.

Troubleshooting

While communicating with Sentry configured in DB mode (based on some versions of MariaDB) through Hive or Impala, you might get an exception:

```
Specified key was too long; max key length is 3072 bytes
java.sql.SQLException: Specified key was too long; max key
length is 3072 bytes
```

This can happen if you install MariaDB version 10.3.17-1.module_el8.1, which is included by default with CentOS 8.1.

HPE recommends upgrading the MariaDB version to 10.4.14 or later and restarting the Sentry service.

You might also get an exception with MySQL versions 5.7.31-0ubuntu0.16.04.1 or 8.0.21-1.el6.x86_64 or other versions of MySQL.

For MySQL, HPE recommends manually altering the `SENTRY_DB_PRIVILEGE` table to reduce the total size of the unique key to a max value of 383:

```
mysql> use <sentry_store_db>
mysql> ALTER TABLE SENTRY_DB_PRIVILEGE MODIFY URI VARCHAR(383);
```

Then restart MySQL, Sentry, and Hive services.

Configure Sentry to use File-Based Storage

You can configure Sentry to use the file-based storage model where permissions are stored in the `global-policy.ini`.

-  **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

As of Sentry 1.6.0-1602, the properties in step 1 are configured by default.

1. In the sentry-xml file (/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml), edit or verify the configuration of the following verify properties:

| Property | Configuration |
|-------------------------------|---|
| sentry.hive.provider.backend | Set the value to org.apache.sentry.provider.file.SimpleFileProviderBackend |
| sentry.hive.provider.resource | Set the value to the location of the global-policy.ini. |

For example:

```
<property>
    <name> sentry.hive.provider.backend </name>
    <value>
org.apache.sentry.provider.file.SimpleFileProviderBackend </value>
    <description> The privilege provider to be used
(either file-based or db-based). </description>
</property>

    <property>
    <name> sentry.hive.provider.resource </name>
    <value> file:///opt/mapr/sentry/sentry-<version>/
conf/global-policy.ini </value>
    <description> Provides location of the policy
file. If the policy file is in the filesystem, then the URL should start
from next schema: 'maprfs:///'. </description>
</property>
```

2. Complete the steps to integrate Hive with Sentry. This includes the step to configure the global-policy.ini file. See [The global-policy.ini File](#) on page 4029

Configure Sentry to use Kerberos Authentication

You can configure Sentry to run in a secure cluster that uses Kerberos authentication.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The same settings are valid for both the file-based and database storage modes.

1. Configure the following properties in the /opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml file:

```
<property>
    <name>sentry.service.security.mode</name>
    <value>kerberos</value>
    <description>Options: kerberos, other, none. Authentication mode for
Sentry service.</description>
</property>
<property>
    <name>sentry.hive.testing.mode</name>
    <value>>false</value>
</property>
```

2. Add the following properties to `/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`:

```
<property>
  <name>sentry.service.server.principal</name>
  <value>mapr/<FQDN@REALM></value>
</property>
<property>
  <name>sentry.service.server.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value>
</property>
<property>
  <name>sentry.service.allow.connect</name>
  <value>mapr,hive,impala</value>
</property>
```

3. Before starting Sentry, use the kinit tool:

```
kinit -kt /opt/mapr/conf/mapr.keytab -p mapr/<CLUSTER_NAME@REALM>
```

Example

```
kinit -kt /opt/mapr/conf/mapr.keytab -p mapr/my.cluster.com@NODE1
```

Integrating Sentry

Integrate Sentry with other ecosystem components to enable those components to use Sentry authorization. You can also integrate Sentry with Hue in order to use the Hue Security application to manage Sentry privileges and roles.

-  **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.
-  **Important:** Sentry is supported with Impala, Hive, and Hue only if you buy Impala support and configure Impala to use Sentry.

You can configure Sentry to provide authorization in the following scenarios:

| Sentry Version | Sentry Storage Mode | Component Integration |
|----------------|---------------------|-----------------------------|
| 1.6.0 | Database | Impala 2.2.0 and Hive 1.2.1 |
| 1.6.0 | File-Based | Impala 2.2.0 and Hive 1.2.1 |
| 1.4.0 | File-Based | Impala 1.4.1 and Hive 0.13 |

Note:

- When you configure Impala to use Sentry authorization, both Impala and Hive must use Sentry for authorization management. Also, impersonation cannot be enabled for Hive.
- For clusters with Hive but not Impala, authorization can be implemented using Hive's native authorization mechanisms; Sentry is not needed.

Configure Impala to Use Sentry Authorization

You can configure Impala to work with Sentry for authorization. When you configure Sentry authorization for Impala, Impala uses operating system IDs to associate privileges with each user that runs the `impala-shell` or client program.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Before you can configure Impala for Sentry authorization, you must have Hive and Sentry installed and configured to work together.

The following table provides the and component versions required when you want to configure Impala to use Sentry authorization:

| Component | Versions |
|-----------|-----------------|
| Release | 6.2.0 |
| Impala | Impala 2.12.0.x |
| Sentry | Sentry 1.7.0 |
| Hive | Hive 2.3.7 |

Configure Impala to Use Sentry Authorization With the Database Storage Model

As of Sentry 1.6, Sentry can be configured to use the Database storage model. Complete the following steps to configure Impala to use Sentry authentication when Sentry uses the DB storage model:

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

1. Set the following properties in env.sh (/opt/mapr/impala/impala-<version>/conf/env.sh):

```
IMPALA_SERVER_ARGS=" -server_name=HS2 -sentry_config=<SENTRY-HOME>/conf/sentry-site.xml
IMPALA_CATALOG_ARGS=" -sentry_config=<SENTRY-HOME>/conf/sentry-site.xml
IMPALA_STATE_STORE_ARGS=" -sentry_config=<SENTRY-HOME>/conf/sentry-site.xml
```

Note: SENTRY-HOME is a variable used in place of the ecosystem component home directory. Typically, the default ecosystem component home directory for a component is /opt/mapr/<component>/<component>-<version>/.

2. Run the following commands to restart Impala:

```
sudo -u mapr maprcli node services -name impalaserver -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalastore -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalacatalog -action
restart -nodes <nodename>
```

3. When Impala is running, you can issue the following command to start the impala-shell as a particular user:

```
impala-shell -u <user_name>
```

Configure Impala to Use Sentry Authorization in File-Based Storage Model

Impala reads the file and controls which objects users can access and what operations they can perform on the objects. Impala caches the security information in the policy file every five minutes. If you make significant changes to security policies, restart Impala. Changes immediately take effect.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

1. Edit `env.sh` located in `/opt/mapr/impala/impala-<version>/conf/`.
2. In the `IMPALA_SERVER_ARGS` declaration, add the following options:

| Option | Description |
|---|---|
| <code>-server_name</code> | This option turns on Sentry authorization for Impala. Specify the symbolic server name to use as the argument for this option. You must also specify this server name as the value for the <code>sentry.hive.server</code> property in the <code>sentry-site.xml</code> configuration file for Hive. For example: <code>-server_name=<hive_server_2></code> |
| <code>-authorization_policy_file</code> | You can store privileges in an authorization policy file. When you specify this option, in addition to the <code>server_name</code> option, Impala reads privilege information from the policy file instead of a database. Specify the filesystem path to the policy file that contains the privilege information. For example: <code>- authorization_policy_file=file:///opt/mapr/sentry/sentry-/conf/.ini \</code>  Note: If the policy file is stored in filesystem, indicate the filesystem location using the following format: <code>-authorization_policy_file=maprfs:/// <path_to_policy_file></code> |

3. Restart the Impala server, statestore service, and catalog service.

```
sudo -u mapr maprcli node services -name impalaserver -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalastore -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalacatalog -action
restart -nodes <nodename>
```

Note: Impala does not start if it detects any issues in the authorization settings or the policy file.

4. When Impala is running, you can issue the following command to start the `impala-shell` as a particular user:

```
impala-shell -u <user_name>
```

Configure Hive to use Sentry Authorization

Configure Hive to use Sentry when you want to use Sentry authorization with Impala.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Complete the following steps to configure Hive to use Sentry authorization, and create an `admin` role for the `mapr` user:

1. For Sentry 1.6.0 and Hive 1.2, add the following properties to `hive-site.xml`:

```
<property>
  <name>hive.server2.session.hook</name>
  <value>org.apache.sentry.binding.hive.HiveAuthzBindingSessionHook</
value>
</property>
<property>
  <name>hive.sentry.conf.url</name>
  <value>file:///opt/mapr/sentry/sentry-<version>/conf/
sentry-site.xml</value>
  <description>sentry-site.xml file location</description>
</property>
<property>
  <name>hive.metastore.rawstore.impl</name>
  <value>org.apache.sentry.binding.metastore.AuthorizingObjectStore</
value>
</property>
<property>
  <name>hive.metastore.filter.hook</name>

  <value>org.apache.sentry.binding.metastore.SentryMetaStoreFilterHook</
value>
</property>
<property>
  <name>hive.server2.enable.doAs</name>
  <value>>false</value>
  <description>Set this property to enable impersonation in
Hive Server 2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>>true</value>
</property>
<property>
  <name>hive.sentry.subject.name</name>
  <value>mapr</value>
</property>
<property>
  <name>hive.stats.collect.scancols</name>
  <value>>true</value>
  <description>Property for use column level privileges in
Hive and Sentry Integration</description>
</property>
```

Note: The `hive.metastore.rawstore.impl` property is optional, but is recommended for [metadata read protection](#).

2. If Sentry uses the database storage model for rules, add the following properties to `hive-site.xml`:

```

<property>
  <name>hive.support.concurrency</name>
  <description>Enable Hive's Table Lock Manager Service</description>
  <value>true</value>
</property>
<property>
  <name>hive.zookeeper.quorum</name>
  <description>ZooKeeper quorum used by Hive's Table Lock Manager</
description>
  <value>hostname</value>
</property>
<property>
  <name>hive.zookeeper.client.port</name>
  <description>The port where the clients connect</description>
  <value>5181</value>
</property>
<property>
  <name>hive.security.authorization.task.factory</name>

<value>org.apache.sentry.binding.hive.SentryHiveAuthorizationTaskFactoryI
mpl</value>
</property>
<property>
  <name>hive.metastore.rawstore.impl</name>
  <value>org.apache.sentry.binding.metastore.AuthorizingObjectStore</
value>
</property>
<property>
  <name>hive.metastore.pre.event.listeners</name>
  <value>org.apache.sentry.binding.metastore.MetastoreAuthzBinding</
value>
  <description>list of comma separated listeners for metastore
events.</description>
</property>

```

3. To configure Sentry with Hive 2.1 or later, add the following properties to `HIVE_HOME/conf/hive-site.xml`:

```

<property>
  <name>hive.server2.session.hook</name>

  <value>org.apache.sentry.binding.hive.v2.HiveAuthzBindingSessionHookV2</
value>
</property>
<property>
  <name>hive.sentry.subject.name</name>
  <value>mapr</value>
  <description>sentry-site.xml file location</description>
</property>
<property>
  <name>hive.sentry.conf.url</name>
  <value>file:///opt/mapr/sentry/sentry-1.7.0/conf/sentry-site.xml</
value>
  <description>sentry-site.xml file location</description>
</property>
<property>
  <name>hive.security.authorization.task.factory</name>

  <value>org.apache.sentry.binding.hive.v2.SentryHiveAuthorizationTaskFacto
ryImplV2</value>
</property>
<property>
  <name>hive.metastore.rawstore.impl</name>

  <value>org.apache.sentry.binding.hive.v2.metastore.AuthorizingObjectStore
V2</value>
</property>
<property>
  <name>hive.metastore.filter.hook</name>

  <value>org.apache.sentry.binding.metastore.SentryMetaStoreFilterHook</
value>
</property>
<property>
  <name>hive.server2.enable.doAs</name>
  <value>>false</value>
  <description>Set this property to enable impersonation in Hive
Server 2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
</property>
<property>
  <name>hive.internal.ss.authz.settings.applied.marker</name>
  <value>true</value>
</property>
<property>
  <name>hive.security.authorization.manager</name>
  <value>org.apache.sentry.binding.hive.v2.SentryAuthorizerFactory</
value>
</property>
<property>
  <name>hive.security.authenticator.manager</name>

  <value>org.apache.hadoop.hive.ql.security.SessionStateUserAuthenticator</
value>
</property>

```

```

<property>
  <name>hive.security.authorization.enabled</name>
  <value>>true</value>
</property>
<property>
  <name>hive.metastore.pre.event.listeners</name>

<value>org.apache.sentry.binding.hive.v2.metastore.MetastoreAuthzBindingV
2</value>
  <description>list of comma separated listeners for metastore
events.</description>
</property>
<property>
<name>hive.metastore.event.listeners</name>

<value>org.apache.sentry.binding.hive.v2.metastore.SentryMetastorePostEve
ntListenerV2</value>
  <description>list of comma separated listeners for metastore, post
events.</description>
</property>
<property>
  <name>hive.zookeeper.client.port</name>
  <value>5181</value>
  <description>The Zookeeper client port. The MapR default clientPort
is 5181.</description>
</property>
<property>
  <name>hive.zookeeper.quorum</name>
  <description>Zookeeper quorum used by Hive's Table Lock Manager</
description>
  <value><!--host with Zookeeper--></value>
</property>

```

4. Restart HiveServer2 and the Hive Metastore:

```

sudo -u mapr maprcli node services -name hs2 -action restart -nodes
<nodename>
sudo -u mapr maprcli node services -name hivemeta -action restart -nodes
<nodename>

```

5. If Sentry was configured to use the database storage model, issue the following command to restart Sentry:

```

sudo -u mapr maprcli node services -name sentry -action restart -nodes
<nodename>

```

6. Create the admin role.

- For the database storage model, run the following commands from the Hive beeline to create the admin role for the mapr user:

```

>create role admin_role;
>grant all on server HS2 to role admin_role;
>grant role admin_role to group mapr;

```

- For the file-based model, update the [The global-policy.ini File](#) on page 4029 in `/opt/mapr/sentry/sentry-<version>/conf`. For example:

```
[groups]
mapr = admin_role
testuser = test_role
[roles]
admin_role = server=HS2
test_role = server=HS2->db=test_db1->table=test_table->action=all
```

Note: If you include a non-existent mapping or path to a JAR file that represents a UDF (user-defined function) in any section of the `global-policy.ini` file, Sentry silently fails and cannot control access to Hive. For example, if you include a mapping to a role that does not exist in the `[groups]` section, Sentry fails. For more information, see [Getting Started with Sentry in Hive](#).

Integrate Hue with Sentry

You can integrate Hue with Sentry 1.6 on a secure cluster that uses Kerberos authentication; however, the integration is not supported on a secure cluster using data-fabric-SASL authentication. Integrate Hue with Sentry when you want to use the Hue Security application to manage Sentry roles and privileges. When you integrate Hue with Sentry, Sentry must use the database storage model.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Note: The Hue user that manages Sentry roles and privileges in Hue must belong to a Hue group that is also part of the Sentry admin group.

1. In the `[libsentry]` section of the `hue.ini` (`/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini`), configure the following properties:

```
[libsentry]
# Hostname or IP of server.
hostname=localhost

# Port the sentry service is running on.
port=8038

# Sentry configuration directory, where
sentry-site.xml is located.
sentry_conf_dir=/opt/mapr/sentry/
sentry-<version>/conf/sentry-site.xml
```

2. If Sentry uses Kerberos authentication, edit the following property in `sentry-site.xml` (`/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`) to enable the Hue admin user (mapr) to connect to Sentry:

```
<property>
    <name>sentry.service.allow.connect</name>
    <value>impala,hive,mapr</value>
</property>
```

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

Sentry 1.7.0 API Changes

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

This page lists the API changes that occurred between Sentry 1.6.0 and Sentry 1.7.0:

Added Classes

```
org.apache.sentry.binding.metastore.AuthorizingObjectStoreBase

org.apache.sentry.binding.metastore.SentryMetastorePostEventListenerBase
org.apache.sentry.binding.hive.v2.HiveAuthzBindingHookV2
org.apache.sentry.binding.hive.v2.HiveAuthzBindingSessionHookV2
org.apache.sentry.binding.hive.v2.HiveAuthzPrivilegesMapV2
org.apache.sentry.binding.hive.v2.SentryAuthorizerFactory

org.apache.sentry.binding.hive.v2.SentryHiveAuthorizationTaskFactoryImplV2
org.apache.sentry.binding.hive.v2.SentryHivePrivilegeObject

org.apache.sentry.binding.hive.v2.authorizer.DefaultSentryAccessController

org.apache.sentry.binding.hive.v2.authorizer.DefaultSentryValidator
org.apache.sentry.binding.hive.v2.authorizer.SentryHiveAuthorizer

org.apache.sentry.binding.hive.v2.metastore.AuthorizingObjectStoreV2

org.apache.sentry.binding.hive.v2.metastore.MetastoreAuthzBindingV2

org.apache.sentry.binding.hive.v2.metastore.SentryMetastorePostEventListener
V2
    org.apache.sentry.binding.hive.v2.util.SentryAuthorizerUtil

Livy

Apache Livy is primarily used to provide integration between Hue and Spark.

Beginning with EEP 4.0.0, Livy is included as its own package in EEP repositories. Before EEP 4.0.0, Livy was included as `mapr-hue-livy` and released only as a part of Hue. For more information about Livy, see [Apache Livy](#).

This documentation set covers the following topics for Livy:

- [Installing Livy](#) on page 196
- [Configure Livy](#) on page 4045
- [Pre-Upgrade Steps for Livy](#) on page 292
- [Upgrading Livy](#) on page 313
- [Post-Upgrade Steps for Livy](#) on page 331

Livy Limitations

This page describes some limitations of the HPE Ezmeral Data Fabric implementation of Apache Livy.

Current limitations are as follows:

- The Livy programmatic Java/Scala/Python API is not supported.
- Livy artifacts are not published in the public Maven repository with other HPE Ezmeral Data Fabric artifacts.

Configure Livy

This topic describes how to configure Livy.

For information about the required package names to configure the Livy server, see [Livy](#) on page 4045.

Configure Livy with Security

On secure clusters, data-fabric SASL authentication, encryption, and impersonation for Livy are enabled by default.

The Livy user interface is available on port 8998. To start the user interface, open a browser, and navigate to the following address:

```
https://<hostname>:8998
```

Configure Livy on Kerberos

This topic describes how to configure Livy on Kerberos.

To configure Livy on Kerberos, add the following properties to the `livy.conf` file:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/_HOST@HADOOP.LOCALDOMAIN
livy.server.auth.kerberos.keytab = $KEYTAB
livy.server.launch.kerberos.principal = $USER/_HOST@HADOOP.LOCALDOMAIN
livy.server.launch.kerberos.keytab = $KEYTAB
```

For example:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/node2.cluster@NODE1
livy.server.auth.kerberos.keytab = /opt/mapr/conf/mapr.keytab
livy.server.launch.kerberos.principal = mapr/node2.cluster@NODE1
livy.server.launch.kerberos.keytab = /opt/mapr/conf/mapr.keytab
```

Livy UI on Kerberos

Note: You can login to the Livy UI on a Kerberos setup only using a web browser configured with SPNEGO.

The other option is to configure multiauth authentication on Kerberized configurations to allow you to login to Livy UI not only with SPNEGO/Mapr-Negotiation mechanisms but also with PAM credentials.

Configure Livy with Custom SSL Encryption

This topic describes how to configure Livy with custom SSL encryption.

1. By default, on a secure cluster, Livy reads the `ssl-server.xml` file and configures SSL from this file.
2. If you want to use custom SSL configuration, add the following properties to the `livy.conf` file:

```
## Use this keystore for the SSL certificate and key.
livy.keystore = <path-to-ssl_keystore>

# Specify the keystore password.
livy.keystore.password = <password>

# Specify the key password.
livy.key-password = <password>
```

Configure Livy with Spark Modes

This topic describes how to configure Livy with different Spark modes.

Use these steps to configure Livy:

1. Modify the `livy.conf` file (`/opt/mapr/livy/livy-<version>/conf/livy.conf`):
 - a. If Spark jobs run in local mode, set the `livy.spark.master` property:

```
...
# What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

- b.** If Spark jobs run in YARN mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- c.** If Spark jobs run in Standalone mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- d.** If Spark jobs run in Mesos mode, set the `livy.spark.master` property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

- 2.** To you want to use impersonation with Livy, set `livy.impersonation.enabled` to `true` in `livy.conf`. For example:

```
# If livy should impersonate the requesting users when creating a new
session.
livy.impersonation.enabled = true
```

3. If you want to be able to access Hive through Spark for Livy, you should configure Spark with Hive, and set `livy.repl.enableHiveContext` to `true` in `livy.conf`. For example:

```
...
# Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
# on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

Note: If Hive is installed on a cluster and if Spark is configured on Hive, this property is set to `true` by default: `livy.repl.enableHiveContext = true`.

4. To apply the needed changes, restart the Livy service:

```
maprcli node services -name livy -action restart -nodes <livy node>
```

HPE Ezmeral Data Fabric Event Streams Clients and Tools

Describes the supported HPE Ezmeral Data Fabric Event Streams tools and clients.

HPE Ezmeral Data Fabric Event Streams Tools

Starting in EEP 8.0.0 and Core 6.2, Kafka 2.6.1.0 supports the following tools and components:

- Kafka Streams API 1.1
- KSQL 6.0.0.0
- Kafka REST 6.0.0.0
- Kafka Connect 10.0.0.0
- Kafka Schema Registry 6.0.0.0
- Spark Streaming

For a complete list of supported versions in each EEP, see [Component Versions for Released EEPs](#) on page 5789.

The following points describe the Kafka tools and provide links to additional information:

- [Kafka Streams](#) on page 4066: This tool is a programming library used for creating Java or Scala streaming applications.
- [KSQL](#) on page 4049: This tool is an open source streaming SQL engine that implements continuous, interactive queries.
- [Kafka Schema Registry](#): This tool provides a RESTful interface for storing and retrieving Avro schemas.
- [Kafka REST Proxy](#) on page 4077: This tool is used as a RESTful interface to HPE Ezmeral Data Fabric Event Streams.
- [Kafka Connect](#) on page 4118: This tool is used to stream data between HPE Ezmeral Data Fabric Event Streams and other storage systems.

HPE Ezmeral Data Fabric Event Streams Clients

HPE Ezmeral Data Fabric Event Streams client applications can be developed for HPE Ezmeral Data Fabric Event Streams (as of MapR 5.2.1 with EEP 3.0). The HPE Ezmeral Data Fabric Event Streams clients are based on distributions of librdkafka that works with HPE Ezmeral Data Fabric Event Streams.

- HPE Ezmeral Data Fabric Event Streams C Client - Used to develop HPE Ezmeral Data Fabric Event Streams applications in C. See [HPE Ezmeral Data Fabric Event Streams C Applications](#) on page 3070
- HPE Ezmeral Data Fabric Event Streams Java Client - Used to develop HPE Ezmeral Data Fabric Event Streams applications in Java. See [HPE Ezmeral Data Fabric Event Streams Java Applications](#) on page 3031
- HPE Ezmeral Data Fabric Event Streams Python Client - Used to develop HPE Ezmeral Data Fabric Event Streams applications in Python. This client is available as of MapR 5.2.1 with EEP 3.0. See [HPE Ezmeral Data Fabric Event Streams Python Applications](#) on page 3273

Table

| MapR release | EEP Release | Kafka librdkafka version |
|------------------|-------------|--------------------------|
| As of MapR 6.0.1 | As of 5.0 | 0.11.3 |

KSQL

KSQL is an open-source streaming SQL engine that implements continuous, interactive queries.

Use KSQL to query, read, write, and process data in real-time, at scale, through SQL commands. KSQL interacts directly with the [Kafka Streams API](#), eliminating the need for a Java application.

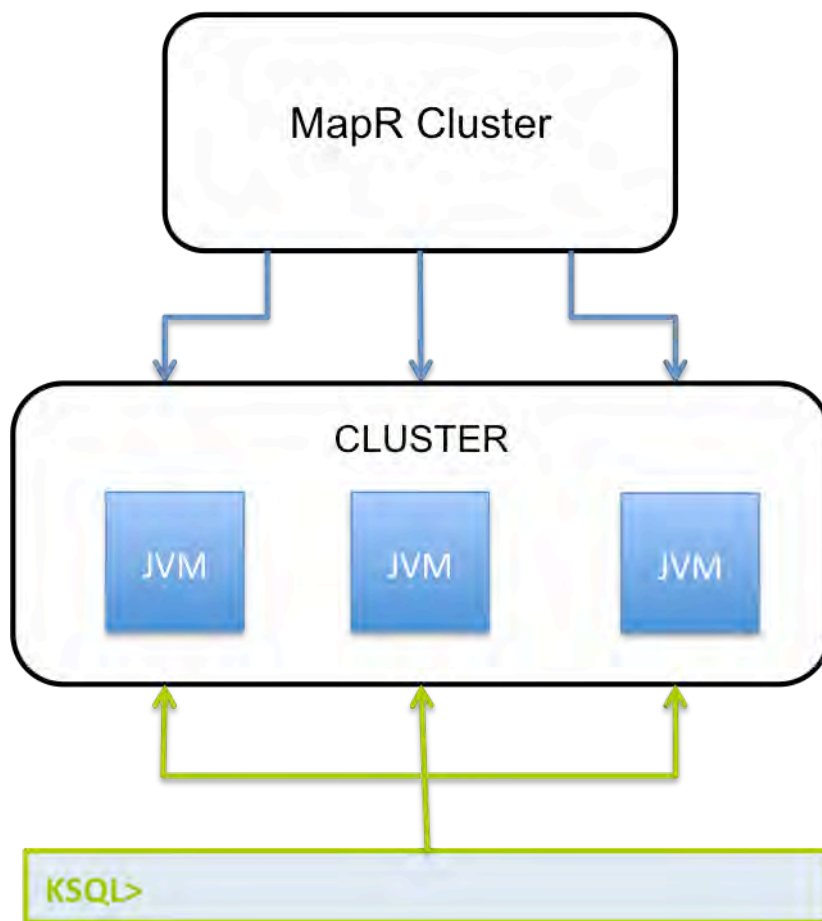

The KSQL data flow architecture is designed such that the user interacts with the KSQL server and the KSQL server interacts with the HPE Ezmeral Data Fabric Event Streams server.

Use Cases

Common use cases include fraud detection, personalization, notifications, real-time analytics, and sensor data and IoT.

Architecture

A set of KSQL processes run as a cluster, and the KSQL server process completes queries. You can dynamically add more processing capacity by starting more instances of the KSQL server. These instances are fault-tolerant: if one fails, the others continue the work. Queries are launched using the interactive KSQL command line client, which sends commands to the cluster over a REST API. The command line allows you to inspect the available streams and tables, issue new queries, check the status of and terminate running queries.

KSQL Server

The KSQL server runs the engine that completes KSQL queries. This includes processing, reading, and writing data to and from the target Kafka cluster. KSQL servers form KSQL clusters and can run in containers, virtual machines, and bare-metal machines. You can add and remove servers in a KSQL cluster during live operations to elastically scale processing capacity. You can deploy different KSQL clusters to achieve workload isolation.

KSQL CLI

You can interactively write KSQL queries through the KSQL command line interface (CLI). The KSQL CLI acts as a client to the KSQL server.

KSQL Deployment Modes

You can deploy KSQL queries through Interactive or Non-Interactive mode.

Interactive Mode

In Interactive mode, users interact with the KSQL server through a REST API, such as the KSQL CLI. Interactive mode is useful when users need to write and verify their queries interactively on a shared KSQL cluster. In interactive KSQL clusters, the authenticated KSQL user must have open access to create, read, write, delete topics, and use of any consumer group.

Starting in EEP 7.0.0 (Core 6.2.0 and KSQL 5.2.1.0), Interactive mode is recommended for production.

Non-Interactive Mode (Headless Mode)

Non-interactive mode supports locked-down or “headless” deployment scenarios where interactive

use of the KSQL cluster is disabled, thereby preventing KSQL CLI access. In this mode, you can write queries to an SQL file, which allows for version control, and lock down access to KSQL servers to prevent users from interacting directly with the KSQL cluster.

KSQL Security

By default, KSQL is secured when installed on secured clusters (clusters secured by the data fabric ticket-based security). See [KSQL Security](#) on page 4051 for additional information.

For More Information

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)
- [Apache Kafka Streams](#)

KSQL Security

Discusses KSQL security topics.

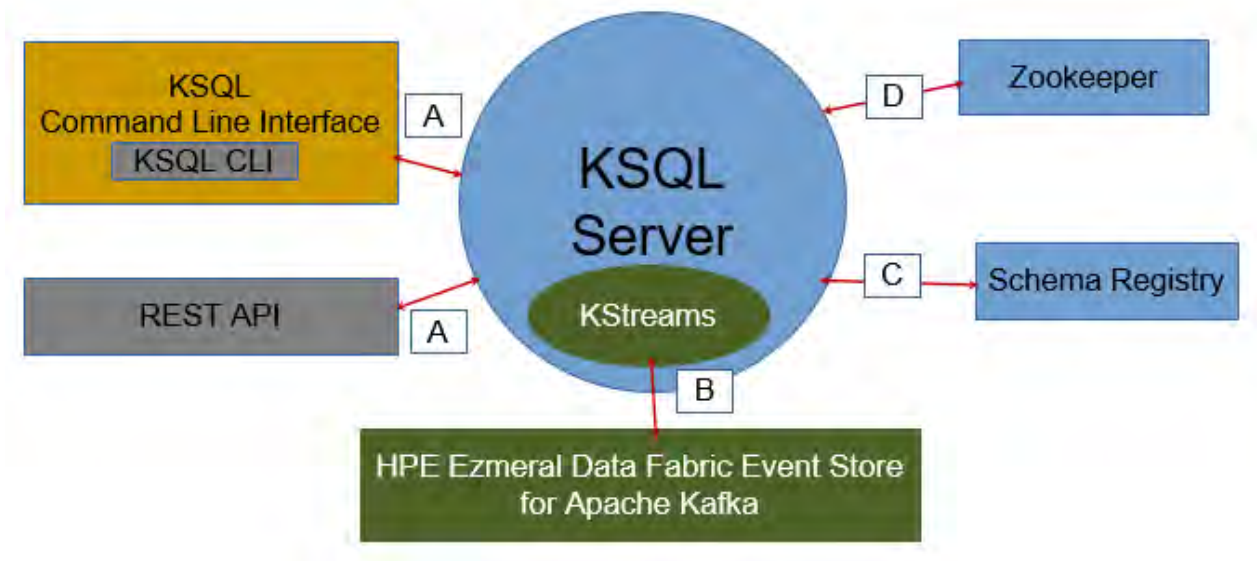

KSQL Security Overview

By default, KSQL is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, impersonation, and authorization. For encryption, SSL/TLS protocols are supported.

If you install KSQL in an insecure cluster, you can enable security through security parameters in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file, as described in [KSQL Security Parameters](#).

KSQL Communication Paths

The following image depicts the KSQL communication paths:

The following table lists the supported security mechanisms for the KSQL communication paths:

Note: Path B does not have a network connection and therefore does not need to be secured. However, impersonation works for this path through KSQL Server.

| Security Features | Supported Mechanisms | Communication Paths Secured |
|-----------------------|--|--|
| Authentication | Data Fabric SASL (ticket-based security) | D - KSQL Server and ZooKeeper |
| | | A - KSQL client (KSQL CLI/REST API) and KSQL server |
| | Basic (PAM) | C - KSQL Server and Schema Registry |
| | | A - KSQL client (KSQL CLI/REST API) and KSQL server |
| | Cookie | C -KSQL Server and Schema Registry |
| | | A - KSQL client (KSQL CLI/REST API) and KSQL server |
| Encryption | Data Fabric SASL (ticket-based security) | D - KSQL Server and ZooKeeper |
| | | A - KSQL client (KSQL CLI/REST API) and KSQL server |
| | SSL/TLS | C -KSQL Server and Schema Registry |
| | | A - KSQL client (KSQL CLI/REST API) and KSQL server |
| | | C - KSQL Server and Schema Registry |
| | | A - KSQL client (KSQL CLI/REST API) and KSQL server |
| Authorization | Based on filesystem permissions | A - KSQL client (KSQL CLI/REST API) and KSQL server |
| Impersonation | User impersonation | A - KSQL client (KSQL CLI/REST API) and KSQL Server |
| | | B - KSQL Server to Streams for Apache Kafka |
| | | C - KSQL Server and Schema Registry |
| Auditing | Not supported | -- |

Impersonation

See [KSQL Impersonation](#) on page 4055.

Authorization

See [KSQL Authorization](#) on page 4054.

Authenticating to KSQL

To authenticate to the KSQL server from the KSQL CLI, include the `--auth` flag and indicate the authentication type for your KSQL environment, for example:

```
ksql --auth MAPRSASL http://<ip-address>:8084
//Note that 8084 is the default port for KSQL.
```

On a secure cluster, the default value for `--auth` is `MAPRSASL`. On an insecure cluster, the default value is `NONE`. The `--auth` flag accepts the following values:

- `--auth BASIC` (For basic or PAM, the system prompts users for a username and password.)
- `--auth MAPRSASL` (For `maprsasl`, a `mapr` user ticket is used.)

- `--auth NONE` (For none, authentication is disabled.)

KSQL COMMANDS

The KSQL COMMANDS internal topic is used to backup information about KSQL streams, KSQL tables, KSQL persistent queries, and so on. KSQL uses KSQL COMMANDS to restore the KSQL server state in case there is a fault or server restart.

Each KSQL Server cluster has a unique service ID which is provided through the `ksql.service.id` property. By default, the `ksql.service.id` is `_default`. To provide additional security, `ksql.service.id`-specific folders are created in the `ksql-internal-stream` stream.

Note: The `/apps` directory has only write access to `mapr` user. Therefore, the `/apps/ksql` directory cannot be modified or deleted by any user other than `mapr` user.

KSQL `ksql.service.id`-specific folders are created in the `/apps/ksql/` directory for every KSQL server cluster (represented by `ksql.service.id`).

Default Stream

KSQL Server provides a default stream for topics when they are being processed. When KSQL Server is not impersonated (non-interactive or interactive+no-impersonation), the KSQL Server default stream is used.

KSQL Cleanup

The KSQL cleanup feature is integrated to ensure that the underlying KSQL state (such as internal topics) are cleaned up correctly. See [Application Reset Tool](#) on page 4072 for more information.

Deployment

The Warden service (`mapr-warden`) manages KSQL Servers in clusters.

Note: A service ID (`ksql.service.id`) is uniquely created for the KSQL implementation; this means that the user associated with the `service` ID cannot grant permissions to other users to use the same service ID.

Cookie Authentication for KSQL

User credentials or challenge strings use cookies to sign requests. After cookies are received on the client side, user credentials or challenge strings are erased from memory. For KSQL, when cookies expire, you have to login again to get the new cookies. Default expiration time for cookies is one week.

Specify a Custom KSQL Truststore Location on a Secure Cluster

By default, the KSQL CLI uses the truststore file located in `/opt/mapr/conf/ssl_truststore` on a secure cluster; however, you can specify a custom SSL truststore file location through properties set from the command line or in the `ksql-server.properties` file.

Use the Default Truststore File

To use the default truststore file while working in the KSQL CLI, run:

```
ksql https://node1.cluster.com:8084
```

Specify a Custom KSQL Truststore from the Command Line

Use the `--truststore` flag with the directory location where the SSL truststore file is located and

the `--truststore-password` with the truststore password, as shown in the following example:

```
ksql https://
node1.cluster.com:8084 --truststore /o
pt/mapr/conf/
ssl_truststore2 --truststore-password
test123
```

For More Information

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)

KSQL Authorization

Describes authorization for Kafka KSQL.

In secure clusters, authorization is enabled by default. In insecure clusters, authorization is disabled by default.

You can enable or disable authorization for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
authorization.enable=[true|false]
```

Permissions

Permissions grant or deny access to users that run commands and maintain background processes that interact with KSQL internal data and structure information, such as persistent queries, tables, streams, and server configuration. *Read* permission grants users and groups access to `FETCH`, `SHOW`, and `DESCRIBE`. *Modify* permission grants users and groups access to `ADD`, `UPDATE`, and `REMOVE`.

Each user or group in a cluster can have no permissions, *read* permission, *modify* permission, or both *read* and *modify* permission to the KSQL service. By default all data-fabric cluster users have both *read* and *modify* permissions.

Internally, the authorization filter is based on *consumeperms* and *produceperms* for the KSQL Kafka store internal stream (`/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`). *Consumeperms* correspond to the KSQL service *read* permissions. *Produceperms* correspond to the KSQL service *modify* permissions. These permissions can be changed by modifying the ACE of *produceperms* and *consumeperms* for `/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`.

The following sections describe KSQL statements that require *read* and *modify* access.

Statements that Require Read Access

DESCRIBE [EXTENDED] ...

List the columns in a stream or table along with its attributes and information.

DESCRIBE FUNCTION ...

Provides a description of a function including an input parameters and the return type.

EXPLAIN ...

Show the execution plan for a SQL expression or, given the ID of a running query, show the execution plan plus additional runtime information and metrics.

PRINT ...

Print the contents of Kafka topics to the KSQL CLI.

SELECT ...

Selects rows from a KSQL stream or table.

| | |
|--|---|
| SHOW ... | List functions, streams, tables, queries, properties. |
| SHOW TOPICS <MAPR_STREAM> | List topics. |

Statements that Require Modify Access

| | |
|---|---|
| CREATE STREAM TABLE ... WITH (...) | Create a new stream or table with the specified columns and properties. |
| CREATE STREAM TABLE ... [WITH (...)] AS SELECT ... | Create a new stream or table and continuously write the result of the SELECT query into the stream. |
| INSERT INTO ... SELECT ... | Stream the result of the SELECT query into an existing stream and its underlying topic. |
| INSERT INTO ... VALUES ... | Produce a row into an existing stream or table and its underlying topic based on explicitly specified values. |
| DROP STREAM TABLE [IF EXISTS] ... | Drops an existing stream or table. |
| DROP STREAM TABLE [IF EXISTS] ... DELETE TOPIC | Drops an existing stream or table and deletes the underlying topic. |
| TERMINATE ... | Terminate a persistent query. |

KSQL Impersonation

Describes impersonation for Kafka KSQL.

The HPE Ezmeral Data Fabric Event Store implementation performs impersonation on behalf of KSQL CLI users in KSQL Servers. Impersonation authorizes the impersonated user to perform permission-sensitive operations. In secure clusters, impersonation is enabled by default. In insecure clusters, impersonation is disabled by default.

Requirement: For impersonation to work, KSQL authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands run as the authenticated user instead of the KSQL principal. The KSQL principal is the user that started KSQL server.

You can enable or disable impersonation for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
impersonation.enable=[true|false]
```

Related concepts

[KSQL Authorization](#) on page 4054

Describes authorization for Kafka KSQL.

KSQL Configuration

Set KSQL configuration and security parameters in the `ksql-server.properties` file. The default port for KSQL is 8084.

Configuring KSQL to Run in Non-Interactive (Headless) Mode

To run KSQL in non-interactive mode, set the parameters shown and then start KSQL.

Note: Note that the `ksql.default.stream` parameter is optional, but recommended. This parameter sets the default stream to consume from and send the messages to. The default stream is used if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message is sent to `/exampleStream:exampleTopic`.

Set the following properties in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://localhost:8084
ksql.default.stream=/sample-stream
```

Start KSQL:

```
$ KSQL_INSTALL_DIR/bin/ksql-server-start /opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties --queries-file some-queries-file.sql
```

Configuring KSQL to Run in Interactive Mode

The following example shows the configuration parameters that you must set in the `ksql-server.properties` file to run KSQL in interactive (distributed) mode:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://192.168.121.73:8084
ksql.default.stream=/sample-stream
```

Note: You must set the `listeners` parameter to an actual IP address.

For more information

- For installation information, see [Installing KSQL](#) on page 187.
- For Apache Kafka information, see the [Apache Kafka Streams API](#), [Apache Kafka Producer Clients](#), and the [Apache Kafka Consumer Clients](#).

KSQL Configuration Parameters

Set the KSQL configuration parameters in the `/opt/mapr/ksql/ksql-<version>/config/ksql-server.properties` file. For more information about configuration parameters, see [KSQL Configuration Parameter Reference](#).

The following table describes some KSQL configuration parameters:

| Parameter | Description |
|--|--|
| <code>ksql.default.stream</code> | The stream that is used when a topic is used without a stream name. |
| <code>ksql.schema.registry.enable</code> | Flag for enabling Avro format support with Schema Registry. Default value: false |
| <code>ksql.schema.registry.service.id</code> | Indicates the ID of the schema registry service. Default value: default_ |
| <code>ksql.schema.registry.discovery.timeout</code> | The timeout (in milliseconds) for requests to Schema Registry URL storage. Default value: 60000 |
| <code>ksql.schema.registry.discovery.retries</code> | The number of retries for Schema Registry URL discovery. Default value: 6 |
| <code>ksql.schema.registry.discovery.interval</code> | The interval (in milliseconds) between retries for Schema Registry URL discovery. Default value: 15000 |

KSQL Security Parameters

Describes KSQL security parameters.

Security parameters provide an authentication, encryption, and impersonation layer between the KSQL clients and the KSQL Server. In secure clusters, KSQL is secured by default. In insecure clusters, you

can enable security through the security parameters in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file.

Requirement: Before you configure KSQL security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table describes KSQL security parameters:

| Parameter | Description | Type | Default |
|---|---|---------|---|
| <code>ksql.schema.registry.maprsasl.auth</code> | Enable MapR Sasl authentication for Avro format with Schema Registry. | boolean | false |
| <code>authentication.cookie.expiration</code> | Authentication cookie expiration time in seconds. | long | 7200 (2 hours) |
| <code>authorization.enable</code> | Set 'true' or 'false' to enable or disable authorization for KSQL service. See KSQL Authorization on page 4054. | boolean | false |
| <code>authentication.enable</code> | Whether or not to enable authentication. | boolean | false |
| <code>impersonation.enable</code> | Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See KSQL Impersonation on page 4055. | boolean | false |
| <code>listeners</code> | Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: http://localhost:8084 | list | none |
| <code>ssl.cipher.suites</code> | A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default. | list | none |
| <code>ssl.cipher.suites.exclude</code> | A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default. | list | <ul style="list-style-type: none"> • TLS_DHE.* • TLS_EDH.* • .DES. • .MD5. • .RC4. |
| <code>ssl.client.auth</code> | Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. <i>This option is not available in KSQL 6.0.</i> | boolean | false |
| <code>ssl.client.authentication</code> | Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. Possible values are NONE, REQUESTED, and REQUIRED. <i>This option is available in KSQL 6.0.</i> | string | none |
| <code>ssl.disabled.protocols</code> | The list of SSL protocols that will not be accepted by clients. This is a comma-separated list. | list | <ul style="list-style-type: none"> • SSLv3 • TLSv1.0 |
| <code>ssl.enabled.protocols</code> | The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults. | list | empty |

| Parameter | Description | Type | Default |
|---------------------------------------|--|---------|---------|
| ssl.endpoint.identification.algorithm | The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default. | string | none |
| ssl.key.password | The password of the private key in the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.  Note: If the <code>ssl-client.xml</code> file is changed, restart KSQL. | string | empty |
| ssl.keymanager.algorithm | The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default. | string | empty |
| ssl.keystore.location | Location of the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.  Note: If the <code>ssl-client.xml</code> file is changed, restart KSQL. | string | empty |
| ssl.keystore.password | The store password for the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.  Note: If the <code>ssl-client.xml</code> file is changed, restart KSQL. | string | empty |
| ssl.keystore.type | The type of keystore file. | string | JKS |
| ssl.protocol | The SSL protocol used to generate the <code>SslContextFactory</code> . | string | TLS |
| ssl.provider | The SSL security provider name. Leave blank to use Jetty's default. | string | none |
| ssl.trustmanager.algorithm | The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default. | string | none |
| ssl.truststore.location | Location of the trust store. Required only to authenticate HTTPS clients. | string | empty |
| ssl.truststore.password | The store password for the trust store file. | string | empty |
| ssl.truststore.type | The type of trust store file. | string | JKS |
| ssl.trustallcerts.enable | Set to true if you want to disable certificates verification. | boolean | false |
| headers.file | The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server. | string | empty |

[KSQL Security](#) on page 4051

Discusses KSQL security topics.

KSQL Reference

KSQL-specific commands are commands for setting your KSQL configuration, exiting the CLI, and so on.

Run the KSQL with `--help` to see the available options.

```
./bin/ksql --help
```

CLI commands include:

- help
- clear
- output
- output <format>
- history
- version
- exit

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

*KSQL Statements***General Syntax**

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

KSQL statements must be terminated with a semicolon (;).

For multi-line statements:

- In the CLI, you use a back-slash (\) to indicate continuation of a statement on the next line.
- Do not use backslashes (\) for multi-line statements in `.sql` files.

CREATE STREAM**CREATE STREAM WITH clause**

Creates a new stream with the specified columns and properties.

```
CREATE STREAM stream_name ( { column_name data_type } [, ...] )
  WITH ( property_name = expression [, ...] );
```

CREATE STREAM WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding HPE Ezmeral Data Fabric Event Streams topic.

```
CREATE STREAM stream_name
  [WITH ( property_name = expression [, ...] )]
  AS SELECT select_expr [, ...]
  FROM from_item [, ...]
  [ WHERE condition ]
  [PARTITION BY column_name]
```

CREATE TABLE

CREATE TABLE WITH clause

Creates a new KSQL table with the specified columns and properties.

```
CREATE TABLE table_name ( { column_name data_type } [, ...] )
    WITH ( property_name = expression [, ...] );
```

CREATE TABLE WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding HPE Ezmeral Data Fabric Event Streams topic and stream.

```
CREATE TABLE table_name
    [WITH ( property_name = expression [, ...] )]
    AS SELECT select_expr [, ...]
    FROM from_item [, ...]
    [ WINDOW window_expression ]
    [ WHERE condition ]
    [ GROUP BY grouping_expression ]
    [ HAVING having_expression ];
```

DESCRIBE

DESCRIBE

Lists the columns in a stream or table along with their data type and other attributes.

```
DESCRIBE (stream_name|table_name);
```

DESCRIBE EXTENDED

Displays DESCRIBE information with additional runtime statistics, HPE Ezmeral Data Fabric Event Streams topic details, and the set of queries that populate the table or stream.

```
DESCRIBE [EXTENDED] (stream_name|table_name);
```

EXPLAIN

EXPLAIN

Shows the execution plan for a SQL expression or, given the ID of a running query, shows the execution plan plus additional runtime information and metrics.

```
EXPLAIN (sql_expression|query_id);
```

DROP STREAM

DROP STREAM

Drops an existing stream

```
DROP STREAM stream_name;
```

DROP TABLE

DROP TABLE

Drops an existing table.

```
DROP TABLE table_name;
```

PRINT**PRINT**

Prints topic contents to the KSQL CLI.

Note: SQL grammar defaults to uppercase formatting. To print topics containing lower-case characters, use quotations.

```
PRINT qualified_name (FROM BEGINNING)? ((INTERVAL | SAMPLE) number)?
```

Print Example

```
ksql> print '/sample-stream:streams-pipe-input' FROM BEGINNING;
Format:STRING
3/16/18 1:04:39 AM EET , 1 , record1
3/16/18 1:04:39 AM EET , 5 , record5
3/16/18 1:04:39 AM EET , 6 , record6
3/19/18 4:22:51 PM EET , null , Hello
3/19/18 4:23:05 PM EET , null , Hello2
```

SELECT**SELECT**

Selects rows from a KSQL stream or table. The result of this statement is not persisted in a topic and is only printed out in the console. To stop the continuous query in the CLI press Ctrl-C.

```
SELECT select_expr [, ...]
      FROM from_item [, ...]
      [ WINDOW window_expression ]
      [ WHERE condition ]
      [ GROUP BY grouping_expression ]
      [ HAVING having_expression ];
```

SELECT CAST expression type

Casts an expression's type to a new type.

```
CAST (expression AS data_type);
```

For example, to convert BIGINT to VARCHAR type:

```
SELECT page_id, CONCAT(CAST(COUNT(*) AS VARCHAR), '_HELLO')
      FROM pageviews_enriched
      WINDOW TUMBLING (SIZE 20 SECONDS)
      GROUP BY page_id;
```

SELECT LIKE operator

The LIKE operator is used for prefix or suffix matching. Currently KSQL supports %, which represents zero or more characters.

```
column_name LIKE pattern;
```

For example:

```
SELECT user_id
FROM users
WHERE user_id LIKE 'santa%';
```

SHOW TOPICS**SHOW TOPICS**

Prints topic information for all topics for the default stream (specified by ksql.default.stream). If the default stream is not specified, then an exception is thrown.

```
SHOW TOPICS;
```

SHOW TOPICS <stream_name>

Prints topic information for all topics from the specified stream. For example: /sample-stream

```
SHOW TOPICS '/sample-stream';
```

SHOW STREAMS**SHOW STREAMS**

List the defined streams.

```
SHOW | LIST STREAMS;
```

SHOW TABLES**SHOW TABLES**

List the defined TABLES.

```
SHOW | LIST TABLES;
```

SHOW QUERIES**SHOW QUERIES**

List the running persistent queries.

```
SHOW | LIST QUERIES;
```

SHOW PROPERTIES

SHOW PROPERTIES

Lists the configuration setting that are currently in effect.

```
SHOW PROPERTIES;
```

TERMINATE**TERMINATE**

Terminate a persistent query. Persistent queries run continuously until they are explicitly terminated

```
TERMINATE query_id;
```

Scalar Functions

The following are scalar functions for KSQL.

Table

| Function | Example | Description |
|---------------------|---|--|
| ABS | ABS(col1) | Absolute value of a value. |
| CEIL | CEIL(col1) | Ceiling of a value. |
| CONCAT | CONCAT(col1, '_hello') | Concatenate two strings. |
| EXTRACTJSONFIELD | EXTRACTJSONFIELD(message, '\$.log.cloud') | Given a string column in JSON format, extract the field that matches. |
| ARRAYCONTAINS | ARRAYCONTAINS(['1, 2, 3'], 3) | Given a JSON or AVRO array, checks if a search value is contained in it. |
| FLOOR | FLOOR(col1) | Floor of a value. |
| LCASE | LCASE(col1) | Convert a string to lowercase. |
| LEN | LEN(col1) | Length of a string. |
| RANDOM | RANDOM() | Returns a random DOUBLE value between 0 and 1.0 |
| ROUND | ROUND(col1) | Round a value to the nearest BIGINT value. |
| STRINGTOTIMESTAMP | STRINGTOTIMESTAMP(col1, 'yyyy-MM-dd HH:mm:ss.SSS') | Converts a string value in the given format into the BIGINT value representing the timestamp. |
| SUBSTRING | SUBSTRING(col1, 2, 5) | Returns the substring with the start and end indices. |
| TIMESTAMP TO STRING | TIMESTAMP TO STRING(ROWTIME, 'yyyy-MM-dd HH:mm:ss.SSS') | Converts a BIGINT timestamp value into the string representation of the timestamp in the given format. |
| TRIM | TRIM(col1) | Trim the spaces from the beginning and the end of the string. |
| CASE | CASE(col1) | Convert a string to uppercase. |

Aggregate Functions

The following are aggregate functions for KSQL.

Table

| Function | Example | Description |
|--------------|-----------------------|---|
| COUNT | COUNT(col1) | Counts the number of rows. |
| MAX | MAX(col1) | Returns the maximum value for a given column and window. |
| MIN | MIN(col1) | Returns the minimum value for a given column and window. |
| SUM | SUM(col1) | Sums the column values. |
| TOPK | TOPK(col1, K) | Returns the TopK values for the given column and window. |
| TOPKDISTINCT | TOPKDISTINCT(col1, K) | Returns the distinct TopK values for the given column and window. |

Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves an inputTopic to an outputTopic:

```
ksql> CREATE STREAM stream3 (message varchar) WITH (kafka_topic='/
sample-stream:inputTopic', value_format='DELIMITED');

ksql> CREATE STREAM stream4 WITH (kafka_topic='/
sample-stream:streams-pipe-output1', value_format='DELIMITED') AS SELECT *
FROM stream3;
```

KSQL Demo

The following demo example creates a stream, performs a non-persistent query, and a persistent query.

Setup

Complete the following steps to prepare your environment for querying:

1. Create a default stream using /sample-stream:

```
maprcli stream create -path /sample-stream
                    -produceperm p -consumeperm p -topicperm p
```

2. Run the following script to generate test data that writes to an HPE Ezmeral Data Fabric Event Streams topic:

```
./bin/ksql-datagen quickstart=pageviews format=delimited
topic=/sample-stream:pageviews maxInterval=10000
```

3. Run KSQL CLI and create a KSQL table:

```
> ./bin/ksql
ksql> CREATE TABLE pageviews_original_table
      (viewtime bigint, userid varchar, pageid varchar)
      WITH (kafka_topic='/sample-stream:pageviews',
           value_format='DELIMITED', key='viewtime');
```

Attention: Note the following for KSQL 6.0:

- A table created on top of a Kafka topic does not materialize into a view because queries on such tables would be highly inefficient.
- KSQL does not support pull queries on tables created by the CREATE TABLE command; however, you can issue pull queries against tables created by the CREATE TABLE AS SELECT statement.

```
ksql> CREATE STREAM pageviews
  (viewtime BIGINT,
   userid VARCHAR,
   pageid VARCHAR)
  WITH (KAFKA_TOPIC='/sample-stream:pageviews',
        VALUE_FORMAT='DELIMITED');

ksql> CREATE TABLE PAGEVIEWS_TABLE
  WITH(KAFKA_TOPIC='/sample-stream:pageviews_table')
  AS
  SELECT userid,
         MAX(viewtime)
  FROM pageviews
  GROUP BY userid;
```

4. Run the SHOW TABLES command to list your KSQL tables:

```
ksql> SHOW TABLES;
```

Run a Non-persistent Query

For a non-persistent query, run:

```
ksql> SELECT * FROM pageviews_original_table;
```

For a non-persistent query in KSQL 6.0, run:

```
ksql> SELECT * FROM PAGEVIEWS_TABLE WHERE userid='User_1';
```

Run a Persistent Query

For a persistent query, do the following:

1. Create the topic, /sample-stream:input-topic:

```
maprcli stream topic create -path /sample-stream -topic input-topic
```

2. Create a KSQL input stream:

```
ksql> CREATE STREAM stream1 (message varchar) WITH
  (kafka_topic='/sample-stream:input-topic' ,
   value_format='DELIMITED');
```

3. Create persistent query with filtering:

```
ksql> CREATE STREAM stream2
      WITH (kafka_topic='/sample-stream:output-topic' ,
           value_format='DELIMITED')
      AS SELECT * FROM stream1 WHERE LEN(message) > 2;
```

4. List your queries:

```
ksql> SHOW QUERIES;
```

5. Run the provided sample code for the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092 --topic /sample-stream:input-topic
```

6. Run the provided sample code for the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:output-topic
```

7. Produce some data:

```
>Hi
>Hello
>No
>Yes
```

8. Get the next results:

```
Hello
Yes
```

Auxiliary Scripts Location

The sample code for `kafka-console-producer.sh` and `kafka-console-consumer.sh` is packaged with MapR Kafka. Once MapR Kafka is installed, you can find them at:

```
/opt/mapr/kafka/kafka-<version>/bin/
```

Kafka Streams

Kafka Streams is a programming library used for creating Java or Scala streaming applications and, specifically, building streaming applications that transform input topics into output topics.

Kafka Streams allows you to build moderately complex operational streaming applications faster by offloading common functions such as failure recovery, joins and enrichment, and aggregations and windowing.

Kafka Streams application is a distributed Java application that is launched with one or more Kafka Streams application instances. Kafka Streams applications can be built using the KStream library. A KStream application instance is required to be provided with an `application.id` property. The `application.id` property uniquely identifies the Kafka Streams distributed application.

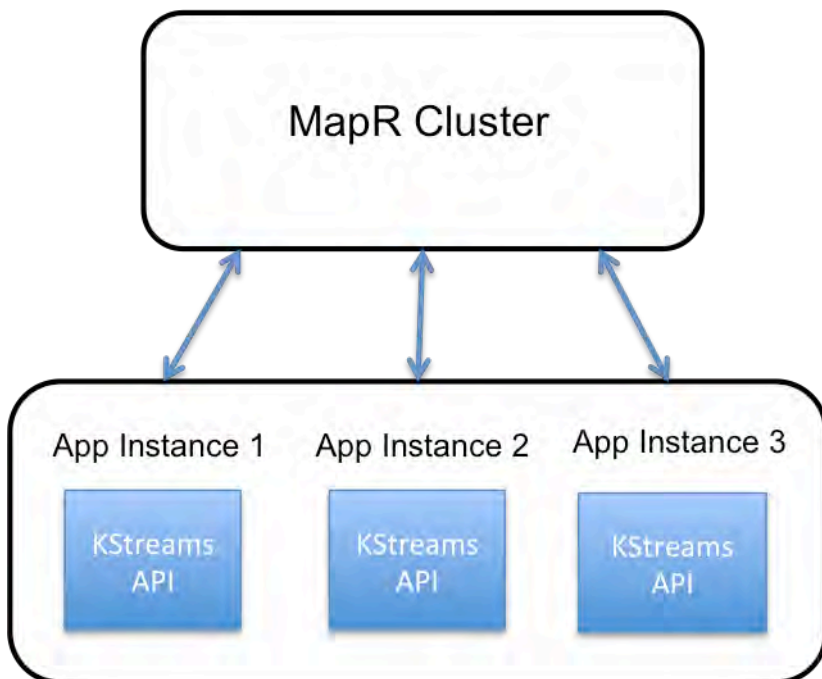

Attention: The Kafka Streams application must always be launched as the same user.

Architecture

An application that uses the Kafka Streams API is a normal Java application. Package, deploy, and monitor it like you would do for any other Java application. There is no need to install separate processing clusters or similar special-purpose and expensive infrastructure.

Note: You can run one or more instances of your application. They run independently but will automatically discover each other and collaborate. In addition, you can elastically add and remove application instances during live operations. If one instance dies, another instance continues where that instance left off.

The following diagram shows an application that is running three (3) application instances.

For More Information

[Apache Kafka Streams](#)

Kafka Streams Configuration

Describes how to configure Kafka Streams.

Kafka Streams Configuration

To configure Kafka Streams, set the following parameters in the Java API StreamsConfig instance:

- (Optional) Set the HPE Ezmeral Data Fabric Event Streams `streams.default.stream` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

The default stream is used to consume from and send the messages to, if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message will be sent to `/exampleStream:exampleTopic`.

Note: If the default stream option is not set and the topic name is specified without a stream name, an exception is thrown.

- Set the Apache Kafka Streams `application.id` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

For more information

- For installation information, see [Installing Kafka Streams](#) on page 188.
- For Apache Kafka Streams information, see [Apache Kafka Streams: Configuring a Streams Application](#).

Supported Apache Kafka Streams APIs

Specifies the supported and not supported Apache Kafka Streams APIs.

Supported APIs

MapR Kafka Streams uses the same APIs as Apache Kafka Streams. Behavior for HPE Ezmeral Data Fabric Event Streams is the same as for Apache Kafka Streams. See [Apache Kafka Streams documentation](#).

Not Supported APIs

The following `stream` methods in the `StreamsBuilder` class are not supported:

- ```
<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern)
```
- ```
<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern,
Consumed<K,V> consumed)
```

Use the following `stream` method instead:

- ```
<K,V> KStream<K,V>stream(java.util.Collection<java.lang.String> topics)
```

### Running a Kafka Streams Java App

Describes how to set up and run a Kafka Streams Java application.

#### Setup

To set up your project, add the required dependencies to the `pom.xml` file, as shown in the example. Note that the versions you use may differ from the versions shown in the example. Version numbers typically change with new releases.

Maven artifacts are published to <https://repository.mapr.com/maven/>. You can also refer to [Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4371 for dependency versions.

#### Example pom.xml

The following example shows the dependencies you must add to `pom.xml`.

```
<repository>
 <id>mapr-releases</id>
 <url>https://repository.mapr.com/maven/</url>
</repository>
<dependency>
 <groupId>org.apache.kafka</groupId>
 <artifactId>kafka-clients</artifactId>
 <version>2.1.1.200-mapr-710</version>
</dependency>
```

```

<dependency>
 <groupId>org.apache.kafka</groupId>
 <artifactId>kafka-streams</artifactId>
 <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
 <groupId>com.mapr.streams</groupId>
 <artifactId>mapr-streams</artifactId>
 <version>6.2.0.0-mapr</version>
</dependency>
<dependency>
 <groupId>org.rocksdb</groupId>
 <artifactId>rocksdbjni</artifactId>
 <version>5.7.3</version>
</dependency>
<dependency>
 <groupId>commons-logging</groupId>
 <artifactId>commons-logging</artifactId>
 <version>1.1.1</version>
</dependency>

```

**Important:** For Kafka 2.6.1, enter 5.18.4 as the rocksdbjni version, and use kafka-eventstreams instead of mapr-streams, as shown:

```

<dependency>
 <groupId>org.rocksdb</groupId>
 <artifactId>rocksdbjni</artifactId>
 <version>5.18.4</version>
</dependency>
<dependency>
 <groupId>com.mapr.kafka</groupId>
 <artifactId>kafka-eventstreams</artifactId>
 <version>0.1.0.0-eep-800</version>
</dependency>

```

## Running a Kafka Streams App on a Cluster

To run a Kafka Streams Java application on a cluster:

1. Copy the <Kafka Streams Java application>.jar file to an arbitrary folder on your cluster.
2. Run the following shell command on your cluster:
  - For Kafka 2.1.1, run:

```
java -cp "$(mapr clientclasspath):<Kafka Streams Java application>.jar" <Kafka Streams Application Main Class Name>
```

- For Kafka 2.6.1, run:

```
java cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka<version>/libs/kafka-eventstreams<version>.jar:<Kafka Streams Java application>.jar" <Kafka Streams Application Main Class Name>
```

## Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves records from an inputTopic to an outputTopic:

```
...
final StreamsBuilder builder = new StreamsBuilder();
KStream<String,String> source = builder stream(inputTopic);
source.to(outputTopic);
final Topology topology= builder.build();
final KafkaStreams streams=new KafkaStreams(topology, props);
...
streams.start();
...
```

### Kafka Streams Demo

Provides a Kafka Streams demo example that creates a stream and topics and runs the WordCountDemo class code. The sample code produces and consumes messages.

1. Create the a stream named /sample-stream:

```
maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p
```

2. Create word-count-input and word-count-output topics:

```
maprcli stream topic create -path /sample-stream -topic word-count-input
maprcli stream topic create -path /sample-stream -topic word-count-output
```

3. Build the word count application and copy its JAR file to your cluster.

4. Run the WordCountDemo class.

- For Kafka 2.1.1 and earlier, run:

```
java -cp "$(mapr clientclasspath):<Word Count Application Name>.jar"
WordCountDemo
```

- For Kafka 2.6.1, run:

```
java -cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka-<version>/libs/
kafka-eventstreams<version>.jar:<Word Count Application Name>.jar"
WordCountDemo
```

5. Run the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092
--topic /sample-stream:word-count-input
```

6. Run the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:word-count-output
--property print.key=true
```

**7. Produce some input with the console producer:**

```
>word27 word28 word27 word29
```

**8. Get the following output:**

```
word28 1
word27 2
Word29 1
```

**WordCountDemo Class Code**

```
import org.apache.kafka.common.serialization.Serdes.StringSerde;
import org.apache.kafka.common.serialization.Serdes;
import org.apache.kafka.common.utils.Bytes;
import org.apache.kafka.streams.KafkaStreams;
import org.apache.kafka.streams.StreamsBuilder;
import org.apache.kafka.streams.StreamsConfig;
import org.apache.kafka.streams.Topology;
import org.apache.kafka.streams.kstream.*;
import org.apache.kafka.streams.state.KeyValueStore;

import java.util.Arrays;
import java.util.Locale;
import java.util.Properties;
import java.util.concurrent.CountDownLatch;

public class WordCountDemo {

 public static final String INPUT_TOPIC = "/
sample-stream:word-count-input";
 public static final String OUTPUT_TOPIC = "word-count-output"; //
Default stream will be used

 public static final String DEFAULT_STREAM = "/sample-stream";

 public static final String APP_ID = "app-id";

 public static void main(String[] args) {
 Properties props = new Properties();
 props.put(StreamsConfig.APPLICATION_ID_CONFIG, APP_ID);
 props.put(StreamsConfig.DEFAULT_KEY_SERDE_CLASS_CONFIG,
StringSerde.class);
 props.put(StreamsConfig.DEFAULT_VALUE_SERDE_CLASS_CONFIG,
StringSerde.class);

 props.put(StreamsConfig.COMMIT_INTERVAL_MS_CONFIG, 500); // Put
attention to this property
 props.put(StreamsConfig.STREAMS_DEFAULT_STREAM_CONFIG,
DEFAULT_STREAM);

 final StreamsBuilder builder = new StreamsBuilder();

 KStream<String, String> wordCountStream = builder.<String,
String>stream(INPUT_TOPIC)
 .flatMapValues(value ->
Arrays.asList(value.toLowerCase(Locale.getDefault()).split("\\W+")))
 .groupBy((key, value) -> value)
```

```

 .count(Materialized.<String, Long, KeyValueStore<Bytes,
byte[]>>as("counts-store"))
 .mapValues(x -> x.toString())

 .toStream();

 wordCountStream.to(OUTPUT_TOPIC, Produced.with(Serdes.String(),
Serdes.String()));

 final Topology topology = builder.build();
 final KafkaStreams streams = new KafkaStreams(topology, props);
 final CountdownLatch latch = new CountdownLatch(1);

 // attach shutdown handler to catch control-c
 Runtime.getRuntime().addShutdownHook(new
Thread("streams-shutdown-hook") {
 @Override
 public void run() {
 streams.close();
 latch.countDown();
 }
 });

 try {
 streams.start();
 latch.await();
 } catch (Throwable e) {
 e.printStackTrace();
 System.exit(1);
 }
 System.exit(0);
 }
}

```

**Note:** The `kafka-console-producer.sh` and `kafka-console-consumer.sh` scripts are part of the `mapr-kafka` package.

### Application Reset Tool

This tool allows you to reset an application and force it to reprocess its data from scratch by using the application reset tool. This tool can be useful for development and testing, or when fixing bugs.

### Description

The application reset tool (ART) handles the Kafka Streams user topics (input, output, and intermediate topics) and internal topics differently when resetting the application.

The application reset tool does the following for each topic type:

- Input topics: Reset to the beginning of the topic. This means that it sets the application's committed consumer offsets for all partitions to each partition's `earliest` offset (for consumer group `application.id`).
- Intermediate topics: Skip to the end of the topic, i.e., set the application's committed consumer offsets for all partitions to each partition's `logSize` (for consumer group `application.id`).
- Internal topics: Delete the internal topic (this automatically deletes any committed offsets).

The application reset tool does not do the following:

- Reset output topics of an application. If any output (or intermediate) topics are consumed by downstream applications, it is your responsibility to adjust those downstream applications as appropriate when you reset the upstream application.

- Reset the local environment of your application instances. It is your responsibility to delete the local state on any machine on which an application instance was run.

See [Confluent Application Reset Tool](#) for additional reference information.

### Running the Application Reset Tool

Invoke the application reset tool from the command line:

```
/opt/mapr/bin/kafka-streams-application-reset.sh
```

The tool accepts the following parameters:

**Note:** Parameters can be combined as needed. For example, if you want to restart an application from an empty internal state, but not reprocess previous data, simply omit the `--input-topics` and `--intermediate-topics` parameters.

| Option                                                  | Description                                                                                                                                           |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--application-id &lt;String: id&gt;</code>        | (Required) The Kafka Streams application ID (application.id).                                                                                         |
| <code>--default-stream</code>                           | The default stream that is used when the topic name is specified but the stream name is not.                                                          |
| <code>--config-file &lt;String: file name&gt;</code>    | Property file containing configs to be passed to admin clients and embedded consumer.                                                                 |
| <code>--dry-run</code>                                  | Display the actions that would be performed without executing the reset commands.                                                                     |
| <code>--input-topics &lt;String: list&gt;</code>        | Comma-separated list of user input topics. For these topics, the tool will reset the offset to the earliest available offset.                         |
| <code>--intermediate-topics &lt;String: list&gt;</code> | Comma-separated list of intermediate user topics (topics used in the <code>through()</code> method). For these topics, the tool will skip to the end. |

### Resetting your Local Environments

To reset the local environments of your application instances, you must delete your application's local state directory on any machines where the application instance was run. You must do this before restarting an application instance on the same machine. You can use either of these methods:

**Note:** This is a complete application reset

The API method `KafkaStreams#cleanUp()` in your application code. Manually delete the corresponding local state directory (default location: `/tmp/kafka-streams/<application.id>`). For more information, see `state.dir` `StreamsConfig` class.

### Example

In this example you are developing and testing an application locally and you want to iteratively improve your application via run-reset-modify cycles.

```
package mapr.examples.streams;

import ...;

public class ResetDemo {

 public static void main(String[] args) throws Exception {
```

```

// Kafka Streams configuration
Properties streamsConfiguration = new Properties();
streamsConfiguration.put(StreamsConfig.APPLICATION_ID_CONFIG,
"my-streams-app");
// ...and so on...

// Define the processing topology
StreamsBuilder builder = new StreamsBuilder();
builder.stream("my-input-topic")
 .selectKey(...)
 .through("rekeyed-topic")
 .countByKey("global-count")
 .to("my-output-topic");

KStreams app = new KafkaStreams(builder.build(), streamsConfiguration);

// Delete the application's local state.
// Note: In real application you'd call `cleanup()` only under
// certain conditions. See tip on `cleanup()` below.
app.cleanup();

app.start();

// Note: In real applications you would register a shutdown hook
// that would trigger the call to `app.close()` rather than
// using the sleep-then-close example we show here.
Thread.sleep(30 * 1000L);
app.close();
}
}

```

You can then perform run-reset-modify cycles as follows:

```

Run your application
$ bin/kafka-run-class mapr.examples.streams.ResetDemo

After stopping all application instances, reset the application
$ bin/kafka-streams-application-reset.sh --application-id my-streams-app \
 --input-topics my-input-topic \
 --intermediate-topics rekeyed-topic

Now you can modify/recompile as needed and then re-run the application
again.
You can also experiment, for example, with different input data without
modifying the application.

```

### Kafka Streams Security

Discusses Kafka Streams security topics.

### Internal Topics

All Kafka Streams application's internal topics are grouped in the Kafka Streams application directory: **/apps/kafka-streams**.

- The **/apps** directory has only write access to **mapr user**. The **/apps/kafka-streams** directory is not modifiable/deletable by any user other than **mapr user**.
- All users can create sub-directories inside the **/apps/kafka-streams** directory. Only the following users have read/write/delete permission for sub-directories or files created in this directory.
  - **mapr user**

- Current user of the sub-directory:
  - If security is enabled, the current user is the MapR ticket identity. See [Managing Tickets](#) on page 1541 for more information.
  - If security is **not** enabled, the current MapR identity.

### Kafka Streams Application Specific Folders

Some Kafka Streams applications need to create internal topics. These topics are created in the **/apps/kafka-streams/<application.id>** directory.

 **Important:** This directory is created at runtime by the Kafka Streams application and can only be modified by the current user or super users. This directory can only be deleted by the [Application Reset Tool](#) on page 4072 (ART) and, again, by only the current user or super users.

### Application Reset Tool and Cleanup APIs

The application reset tool allows to reset a Kafka Streams application's internal state, such that it can re-process its input data from scratch. Kafka Streams internal topics can be cleaned using application reset tool.

Only the current user of the Kafka Streams application or **mapr user** has permissions to clean up a Kafka Streams application using Application Reset Tool. The Application Reset Tool is integrated with the cleanup APIs so that the application's internal topics are prefixed with the same directory.

The application reset tool takes `application.id` as the input for cleaning up Kafka Streams application. As part of this process, all internal-topics are deleted for the application user under the **/apps/kafka-streams/<application.id>** directory, including the **/apps/kafka-streams/<application.id>** directory. See [Application Reset Tool](#) on page 4072 for more information.

### Changes in Kafka 2.6.1

Describes several differences to note when upgrading from Kafka 2.1.1 to 2.6.1.

#### Classpath change

- Kafka 2.6.1 uses classes from `kafka-eventstreams.jar` instead of `mapr-streams.jar` to access the cluster.
- If an application fails with a `ClassNotFoundException` or `NoClassDefFoundError` for classes in packages under `com.mapr.kafka.eventstreams.*`, verify that `kafka-eventstreams.jar` is in the Java classpath. You can find `kafka-eventstreams.jar` in the `/opt/mapr/lib/` directory, or you can download it from the Maven repository.

#### Scala changes

- Scala version 2.11 is no longer supported. Scala versions 2.12 and 2.13 are supported.
- Scala code leveraging the `NewTopic(String, int, short)` constructor with literal values must explicitly call `toShort` on the second literal.

#### RocksDBs change

- Kafka Streams version 2.6.1 requires RocksDB version 5.18.4.

**Default consumer group id**

- The default consumer group id has been changed from the empty string (" ") to `null`. Consumers that use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of the consumer configuration. For more information, see [KIP-289](#).

**client.dns.lookup**

The default value for the `client.dns.lookup` configuration has been changed from `default` to `use_all_dns_ips`. If a hostname resolves to multiple IP addresses, clients and brokers will now attempt to connect to each IP in sequence until the connection is successfully established. For more information, see [KIP-602](#).

**DSL**

- Use the DSL operator, `cogroup()`, to aggregate multiple streams together at once.
- Kafka Streams DSL switches its used store types. While this change is mainly transparent to users, there are some corner cases that may require code changes.

**KStream.toTable() API**

Use the `KStream.toTable()` API to translate an input event stream into a `KTable`.

**Serde type Void**

Use the Serde type, `Void`, to represent null keys or null values from an input topic.

**Sticky partitioning**

The `DefaultPartitioner` now uses a sticky partitioning strategy. This means that records for a specific topic with null keys and no assigned partition will be sent to the same partition until the batch is ready to be sent. When a new batch is created, a new partition is chosen. This decreases latency to produce, but it may result in uneven distribution of records across partitions in edge cases. Generally, users will not be impacted, but this difference may be noticeable in tests and other situations producing records for a very short amount of time.

**Rebalancing**

- We are introducing incremental cooperative rebalancing to the clients' group protocol, which allows consumers to keep all of their assigned partitions during a rebalance and in the end revoke only those which must be migrated to another consumer for the overall cluster balance. The `ConsumerCoordinator` will choose the latest `RebalanceProtocol` that is commonly supported by all of the consumer's supported assignors.

- We are introducing a new rebalancing protocol for Kafka Connect based on incremental cooperative rebalancing. The new protocol does not require stopping all the tasks during a rebalancing phase between Connect workers. Instead, only the tasks that need to be exchanged between workers are stopped and they are started in a follow-up rebalance. The new Connect protocol is enabled by default. For more details on how it works and how to enable the old behavior of eager rebalancing, checkout incremental cooperative rebalancing design.

## Deprecated APIs

- Deprecated `UsePreviousTimeOnInvalidTimestamp` and replaced with `UsePartitionTimeOnInvalidTimeStamps`.
- Provided support to query stale stores (for high availability) and the stores belonging to a specific partition by deprecating `KafkaStreams.store(String, QueryableStoreType)` and replacing it with `KafkaStreams.store(StoreQueryParameters)`.
- The internal `PartitionAssignor` interface has been deprecated and replaced with a new `ConsumerPartitionAssignor` in the public API. Some methods/signatures are slightly different between the two interfaces. Users implementing a custom `PartitionAssignor` should migrate to the new interface as soon as possible.
- The blocking `KafkaConsumer#committed` methods have been extended to allow a list of partitions as input parameters rather than a single partition. It enables fewer request/response iterations between clients and brokers fetching for the committed offsets for the consumer group. The old overloaded functions are deprecated and we would recommend users making their code changes to leverage the new methods
- The default consumer group id has been changed from the empty string ( " ") to `null`. Consumers who use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of their consumer configuration.

## Kafka REST Proxy

The Kafka REST Proxy provides a RESTful interface to HPE Ezmeral Data Fabric Event Streams clusters to consume and produce messages and to perform administrative operations.

It allows you to:

- Consume messages from topics or concrete topic partitions.
- Produce messages to topics or partitions.
- View the state of the cluster.

Use cases include ingesting messages into a stream-processing framework and scripting administrative operations.

### Configuration

This section describes how to configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Event Streams.

You can set these configuration parameters in the `kafka-rest.properties` file. The Control System displays information about the Kafka REST Proxy for the HPE Ezmeral Data Fabric Event Streams service. By default, the service runs on port **8082**.

To install the Kafka REST Proxy, see [Installing HPE Ezmeral Data Fabric Event Streams Tools](#) on page 194.

To configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Event Streams, edit the following file:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

To view the Kafka REST Proxy for HPE Ezmeral Data Fabric Event Streams log files, see the following location:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/logs/kafka-rest.log
```

**Note:** After installation, Warden automatically detects the configuration and starts the service. To configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Event Streams, stop the service, configure the parameters, and restart the service. To stop and restart services, see [maprcli node services](#). For example:

```
maprcli node services -name kafka-rest -action stop
```

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

### Configuration Parameters

This section provides the Kafka REST Proxy for HPE Ezmeral Data Fabric Event Streams parameters.

These parameters are configurable in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

**Note:** Starting in EEP 8.0.0, Schema Registry (version 6.0.0.0) supports Avro, JSON Schema, and Protobuf formats.

**Table**

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>api.v2.enable</code>        | Enables the REST Proxy v2 API when set to <code>true</code> . Default is <code>true</code> . This parameter is available starting in Kafka REST 6.0.0.0.                                                                                                                                                                                               |
| <code>api.v3.enable</code>        | Enables the REST Proxy v3 API when set to <code>true</code> . Default is <code>false</code> . This parameter is available starting in Kafka REST 6.0.0.0.                                                                                                                                                                                              |
| <code>advertised.listeners</code> | List of advertised listeners used when generating absolute URLs in responses. Supports <code>http</code> and <code>https</code> protocols. Each listener must include the protocol, hostname, and port. For example: <code>http://myhost:8080</code> , <code>https://0.0.0.0:8081</code> . This parameter is available starting in Kafka REST 6.0.0.0. |

Table (Continued)

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema.registry.enable             | Enables Avro serialization and deserialization support with Schema Registry. Starting in Schema Registry 6.0.0.0, enables JSON Schema, and Protobuf serialization and deserialization as well as Avro.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| schema.registry.url                | The base URL for the schema registry for use by the Avro serializer. Starting in Schema Registry 6.0.0.0, also for use by the JSON Schema and Protobuf serializers, as well as Avro. This setting is ignored if schema.registry.enable is set to false. The default value is resolved from Zookeeper.                                                                                                                                                                                                                                                                                                                                                                    |
| schema.registry.service.id         | Indicates the ID of the schema registry service. Default: default_                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| schema.registry.discovery.timeout  | The timeout in milliseconds for request to Schema Registry URL storage. Default: 60000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| schema.registry.discovery.retries  | The number of retries for Schema Registry URL discovery. Default: 6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| schema.registry.discovery.interval | The interval in milliseconds between retries for Schema Registry URL discovery. Default: 15000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| streams.default.stream             | The default stream the consumer should poll messages from and the producer should send messages to. If the topic name does not specify the stream path, and the property has a valid value, then this topic name is found in the default stream.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| id                                 | Unique ID for this REST server instance. This is used in generating unique IDs for consumers that do not specify their ID. The ID is empty by default, which makes a single server setup easier to get up and running, but is not safe for multi-server deployments where automatic consumer IDs are used. Type: string. Default: empty                                                                                                                                                                                                                                                                                                                                  |
| consumer.threads                   | The number of threads to run consumer requests on. Type: int. Default: 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| simpleconsumer.cache.max.records   | Maximum number of records that can be stored in a single cache. Records with higher offsets replace records with lower ones. The value must be greater than 0. Type: int. Default: 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| simpleconsumer.max.caches.num      | Maximum number topic-partition combinations for which records are cached. If this parameter is set to 0, then caching is disabled and extra records are thrown away. Cache improves performance if records are fetched sequentially thus increasing offsets.<br><br>A pool of caches are available to store extra fetch records by a KafkaConsumer for a particular TopicPartition. The cache increases performance when records are fetched from a particular topic partition in a sequential manner. For example, every next request will start with the following offset after the offset of the latest fetched record in the previous request. Type: int. Default: 0 |
| simpleconsumer.max.poll.time       | Specifies the maximum number of milliseconds that are spent for polling records by a simpleconsumer. The greater the value means greater latency but higher throughput. Type: int. Default: 1000                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| simpleconsumer.pool.size.max       | Maximum number of SimpleConsumers that can be instantiated. If 0, then the pool size is not limited. Type: int. Default: 25                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| simpleconsumer.pool.timeout.ms     | Amount of time to wait for an available SimpleConsumer from the pool before failing. Use 0 for no timeout. Type: int. Default: 1000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| consumer.instance.timeout.ms       | Amount of idle time (in milliseconds) before a consumer instance is automatically destroyed. Type: int. Default: 300000 (5 minutes)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table (Continued)

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| consumer.iterator.backoff.ms        | Amount of time (in milliseconds) to backoff when an iterator runs out of data. If a consumer has a dedicated worker thread, this is effectively the maximum error for the entire request timeout. This parameter should be small enough to closely target the timeout, but large enough to avoid busy waiting. Type: int. Default: 50                                                                                                                                   |
| consumer.request.max.bytes          | Maximum number of bytes in unencoded message keys and values returned by a single request. This can be used by administrators to limit the memory used by a single consumer and to control the memory usage required to decode responses on clients that cannot perform a streaming decode. Note that the actual payload will be larger due to overhead from base64 encoding the response data and from JSON encoding the entire response. Type: long. Default: 6710884 |
| consumer.request.timeout.ms         | The maximum total time (in milliseconds) to wait for messages for a request if the maximum number of messages has not yet been reached. Type: int. Default: 1                                                                                                                                                                                                                                                                                                           |
| producer.threads                    | Number of threads to run producer requests on. Type: int. Default: 5                                                                                                                                                                                                                                                                                                                                                                                                    |
| producer.streams.buffer.max.time.ms | Buffers messages in the producer for the maximum time specified time. A thread flushes all the messages that have been buffered beyond the time specified. Default: 1                                                                                                                                                                                                                                                                                                   |
| producers.max.caches.num            | Maximum number user names for which producers are cached. If 0, then caching is disabled and producer will be created for each request. Default: 20                                                                                                                                                                                                                                                                                                                     |
| request.logger.name                 | Name of the SLF4J logger to write the NCSA Common Log Format request log. Type: string. Default: io.confluent.rest-utils.requests.                                                                                                                                                                                                                                                                                                                                      |
| response.mediatype.default          | The default response media type that should be used if no specify types are requested in an Accept header. Type: string. Default: application/vnd.kafka.v1+json                                                                                                                                                                                                                                                                                                         |
| response.mediatype.preferred        | An ordered list of the server's preferred media types used for responses, from most preferred to least. Type: list. Default: application/vnd.kafka.v1+json, application/vnd.kafka+json, application/json                                                                                                                                                                                                                                                                |
| access.control.allow.methods        | Sets the value to the Jetty Access-Control-Allow-Origin header for specified methods. Type: string. Default: empty                                                                                                                                                                                                                                                                                                                                                      |
| access.control.allow.origin         | Sets the value for the Jetty Access-Control-Allow-Origin header. Type: string. Default: empty                                                                                                                                                                                                                                                                                                                                                                           |
| host.name                           | The host name used to generate absolute URLs in responses. If empty, the default canonical hostname is used. Type: string. Default: empty                                                                                                                                                                                                                                                                                                                               |
| debug                               | Boolean indicating whether extra debugging information is generated in some error response entities. Type: Boolean. Default: false                                                                                                                                                                                                                                                                                                                                      |
| shutdown.graceful.ms                | Amount of time to wait after a shutdown request for outstanding requests to complete. Type: int. Default: 1000                                                                                                                                                                                                                                                                                                                                                          |
| metric.reporters                    | A list of classes to use as metrics reporters. Implementing the MetricReporterinterface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics. Type: list. Default: empty                                                                                                                                                                                                              |

Table (Continued)

| Parameter                | Description                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| metrics.jmx.prefix       | Prefix to apply to metric names for the default JMX reporter. Type: string. Default: kafka.rest                                                                                                                                                                                                                             |
| metrics.num.samples      | The number of samples maintained to compute metrics. Type: int. Default: 2                                                                                                                                                                                                                                                  |
| metrics.sample.window.ms | The metrics system maintains a configurable number of samples over a fixed window size. This configuration controls the size of the window. For example, used to maintain two samples each measured over a 30 second period. When a window expires, the oldest window is erased and overwritten. Type: long. Default: 30000 |

*Security Parameters*

Describes Kafka REST security parameters.

By default, Kafka REST is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka REST.

Starting in EEP 7.0.0 (Core 6.2.0 and KAKFA REST 5.2.1.0) impersonation and authentication are disabled, by default, in insecure clusters.

Configure security for Kafka REST through the security parameters in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

**Note:** Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

Table

| Parameter                        | Description                                                                                                                                                                                            | Type    | Default        |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|----------------|
| authentication.cookie.expiration | Authentication cookie expiration time in seconds.                                                                                                                                                      | long    | 7200 (2 hours) |
| authentication.enable            | Whether or not to enable authentication.                                                                                                                                                               | boolean | false          |
| impersonation.enable             | Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user.                                                                                | boolean | false          |
| listeners                        | Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8082</code> | list    | none           |
| ssl.cipher.suites                | A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.                                                                                                  | list    | none           |

Table (Continued)

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Type    | Default                                                                                                                               |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------|
| ssl.cipher.suites.exclude             | A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.                                                                                                                                                                                                                                                                                                                                                      | list    | <ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul> |
| ssl.client.auth                       | Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.                                                                                                                                                                                                                                                                                                                                                             | boolean | false                                                                                                                                 |
| ssl.disabled.protocols                | The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.                                                                                                                                                                                                                                                                                                                                                                | list    | <ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>                                                          |
| ssl.enabled.protocols                 | The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.                                                                                                                                                                                                                                                                                                                          | list    | empty                                                                                                                                 |
| ssl.endpoint.identification.algorithm | The endpoint identification algorithm to validate the server hostname using the server certificate. <b>IMPORTANT:</b> Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.                                                                                                                                                          | string  | none                                                                                                                                  |
| ssl.key.password                      | <p>The password of the private key in the keystore file.</p> <p>This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.</p> <p> <b>Note:</b> If the <code>ssl-client.xml</code> file is changed, Kafka REST must be restarted.</p> | string  | empty                                                                                                                                 |
| ssl.keymanager.algorithm              | The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.                                                                                                                                                                                                                                                                                                                                                         | string  | empty                                                                                                                                 |

Table (Continued)

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                        | Type    | Default   |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-----------|
| ssl.keystore.location      | Location of the keystore file.<br><br>This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.<br><br> <b>Note:</b> If the ssl-client.xml file is changed, Kafka REST must be restarted.            | string  | empty     |
| ssl.keystore.password      | The store password for the keystore file.<br><br>This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.<br><br> <b>Note:</b> If the ssl-client.xml file is changed, Kafka REST must be restarted. | string  | empty     |
| ssl.keystore.type          | The type of keystore file.                                                                                                                                                                                                                                                                                                                                                                         | string  | JKS       |
| ssl.protocol               | The SSL protocol used to generate the SslContextFactory.                                                                                                                                                                                                                                                                                                                                           | string  | TLS-v1.2- |
| ssl.provider               | The SSL security provider name. Leave blank to use Jetty's default.                                                                                                                                                                                                                                                                                                                                | string  | none      |
| ssl.trustmanager.algorithm | The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.                                                                                                                                                                                                                                                                                           | string  | none      |
| ssl.truststore.location    | Location of the trust store. Required only to authenticate HTTPS clients.                                                                                                                                                                                                                                                                                                                          | string  | empty     |
| ssl.truststore.password    | The store password for the trust store file.                                                                                                                                                                                                                                                                                                                                                       | string  | empty     |
| ssl.truststore.type        | The type of trust store file.                                                                                                                                                                                                                                                                                                                                                                      | string  | JKS       |
| ssl.trustallcerts.enable   | Set to true if you want to disable certificates verification.                                                                                                                                                                                                                                                                                                                                      | boolean | false     |
| headers.file               | The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.                                                                                                                                                                                                                                                 | string  | empty     |

*SSL Security Configuration*

Describes how to configure Kafka REST security.

## Secure by Default

As of MapR 6.0, the MapR Installer performs the Kafka REST configuration for new installations. This means that:

- If MapR core is installed as *secure*, then Kafka REST is also installed as *secure*.
- If MapR core is installed as *insecure*, then Kafka REST is also installed as *insecure*.

## Manually Securing Kafka REST Only

 **CAUTION:** This configuration is *not* a typical configuration.

If you have an *insecure* MapR cluster, and you want to *secure* Kafka REST, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `kafka-rest.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8082,https://0.0.0.0:8085
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8085/streams/%2Ftesting/topics --cacert
<certificate-path>
```

## Manually Unsecuring Kafka REST

 **Warning:** This scenario is *NOT* recommended or supported.

If you have an *secure* MapR cluster, and you want to *insecure* Kafka REST, do the following:

1. In the `kafka-rest.properties` configuration file, change **https://** to **http://** for the listeners and remove the **ssl.\*** properties. For example:

```
listeners=http://0.0.0.0:8082
```

2. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

### User Impersonation

Describes how to disable, enable, and use impersonation with Kafka REST.

User impersonation enables Kafka REST jobs to be submitted as a particular user. Without impersonation, Kafka REST submits jobs as the user that started Kafka REST server.

On an HPE Ezmeral Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation is disabled for unsecured clusters and enabled for secure clusters.

### Enabling User Impersonation

To enable user impersonation, set the following properties in `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties`:

- `authentication.enable=true`
- `impersonation.enable=true`

### Disabling User Impersonation

In the `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties` file, disable PAM authentication and the `impersonation.enable` property.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable user impersonation, set `impersonation.enable=false`.

### Example: Verify that a list of topics is owned by an impersonated user

This example demonstrates how to get a list of topics from a particular stream and then verifies that the list of topics is owned by a particular user. Depending on whether or not impersonation is enabled (the default), you may need to use a different `curl` command.

```
$ sudo maprcli stream info -json -path /stream
{
 "timestamp":1598950735841,
 "timeofday":"2020-09-01 08:58:55.841 GMT+0000 AM",
 "status":"OK",
 "total":1,
 "data":[
 {
 "path":"/stream",
 "physicalsize":57344,
 "logicalsize":32768,
 "numtopics":1,
 "defaultpartitions":1,
 "ttl":604800,
 "compression":"lz4",
 "autocreate":true,
 "produceperm":"u:root",
 "consumeperm":"u:root",
 "topicperm":"u:root",
 "copyperm":"u:root",
 "adminperm":"u:root",
 "kafkatopic":false,
 "ischangelog":false,
 "defaulttimestamptype":"CreateTime",
 "compact":false,
 "mincompactionlag":0,
 "deleteretention":86400000,
 "throttlefactor":0,
 "pidexpirysecs":604800
 }
]
}
```

If impersonation is enabled (the default), use the following query, where the query is submitted as the root user.

```
curl -u root -X GET https://`hostname`:8082/topics/
%2Fstream%3Atopic1 --cacert /opt/mapr/conf/ssl_truststore.pem
Enter host password for user 'root':
{"name":"/stream:topic1","configs":null,"partitions":
 [{"partition":0,"leader":0,"replicas":
 [{"broker":0,"leader":true,"in_sync":true},
 {"broker":0,"leader":false,"in_sync":true}]}]}
```

If impersonation is disabled, use the following query, where the query is submitted as the `mapr` user.

```
curl -X GET https://`hostname`:8082/topics/%2Fstream%3Atopic1 --cacert /opt/
mapr/conf/ssl_truststore.pem
{"error_code":40401,"message":"Topic not found."}
```

### *Saving Kafka REST Configurations*

Describes how Kafka REST configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka REST is stored in a folder with a timestamp.

- The configuration files are saved *and* overwritten by new configuration files when upgrading from:
  - 4.1.0 to 5.1.2
  - 5.1.2 to 6.0.0.0
- The configuration files are saved only (not overwritten) when upgrading from:
  - 5.1.2 to 5.1.2

### **Example**

The following example shows the list of configuration files that are saved when upgrading from `mapr-kafka-rest 5.1.2 (EEP 7.0.0)` to `mapr-kafka-rest 5.1.2 (EEP 7.0.1)`:

```
ls /opt/mapr/kafka-rest/
kafka-rest-5.1.2 kafka-rest-5.1.2.0.202009100923 kafka-restversion

ls /opt/mapr/kafka-rest/kafka-rest-5.1.2.0.202009100923/config/
headers.xml kafka-rest.properties log4j.properties warden.kafka-rest.conf
```

### **Services Management**

The Kafka REST Proxy for HPE Ezmeral Data Fabric Event Streams service can be started, restarted, and stopped via the `maprcli nodes services` command or using the REST API equivalent.

The following `maprcli nodes services` commands summarize the commands. For more information, see [node services](#) on page 1939.

### **CLI commands**

```
maprcli node services -name kafka-rest -action start -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action restart -nodes <node_list>
```

## REST

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

### HTTP Methods and URI Summary

This section provides HTTP method and URI summaries for multiple Kafka REST Proxy API versions for HPE Ezmeral Data Fabric Event Streams.

### API v3: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v3 started in Kafka REST 6.0.0.0 on Core 6.2.0.

API v3 is disabled by default. To enable API v3, set the `api.v3.enable` parameter in the `kafka-rest.properties` file to `true`. See [Configuration Parameters](#) on page 4078.

**Note:** Kafka REST 6.0.0.0 supports [API v3](#) and [API v2](#) only. Kafka REST 6.0.0.0 does not support API v1.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

| HTTP Method | URI                                                                                                                                                           | Description                                                                                              |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| GET         | <a href="#">GET /v3/clusters</a> on page 4105                                                                                                                 | Retrieves a list of metadata about clusters. Only retrieves the current HPE Ezmeral Data Fabric cluster. |
| GET         | <a href="#">GET /v3/clusters/{string: cluster_id}</a> on page 4106                                                                                            | Retrieves metadata about a specific cluster.                                                             |
| GET         | <a href="#">GET /v3/clusters/{string: cluster_id}/topics</a> on page 4107                                                                                     | Retrieves a list of topic names on the specific cluster.                                                 |
| POST        | <a href="#">POST /v3/clusters/{string: cluster_id}/topics</a> on page 4116                                                                                    | Creates a new topic on the specific cluster.                                                             |
| DELETE      | <a href="#">DELETE /v3/clusters/{string: cluster_id}/topics/{string: topic_name}</a> on page 4117                                                             | Deletes a topic from the specific cluster.                                                               |
| GET         | <a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}</a> on page 4109                                                                | Retrieves metadata about a specific topic within a cluster.                                              |
| GET         | <a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions</a> on page 4110                                                     | Retrieves a list of partitions for the topic within a cluster.                                           |
| GET         | <a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}</a> on page 4112                              | Retrieves metadata about a specific partition within a topic and a cluster.                              |
| GET         | <a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas</a> on page 4114                     | Retrieves a list of replicas within a partition, a topic and a cluster.                                  |
| GET         | <a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas/{string: broker_id}</a> on page 4115 | Retrieves metadata about a specific replica within a partition, a topic and a cluster.                   |

### API v2: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

| HTTP Method | URI                                                                                     | Description                                                                                                                                                                        |
|-------------|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GET         | /topics                                                                                 | Retrieves a list of topic names.                                                                                                                                                   |
| GET         | /topics/{string: topic_name}                                                            | Retrieves metadata about a specific topic.                                                                                                                                         |
| POST        | /topics/{string: topic_name}                                                            | Produces messages to a topic.                                                                                                                                                      |
| GET         | /topics/{string: topic_name}/partitions                                                 | Retrieves a list of partitions for the topic.                                                                                                                                      |
| GET         | /topics/{string: topic_name}/partitions/{string: partition_id}                          | Retrieves metadata about a specific partition within a topic.                                                                                                                      |
| GET         | GET /topics/{string: topic_name}/partitions/{string: partition_id}/offsets on page 4094 | Returns a summary with beginning and end offsets for the given topic and specific partition. Supported as of Kafka Rest 6.0.0.0.                                                   |
| POST        | /topics/{string: topic_name}/partitions/{string: partition_id}                          | Produces messages into a partition of a topic.                                                                                                                                     |
| POST        | /consumers/{string: group_name}                                                         | Creates a new consumer instance in the consumer group.                                                                                                                             |
| DELETE      | /consumers/{string: group_name}/instances/{string: instance_id}                         | Destroys the consumer instance.                                                                                                                                                    |
| POST        | /consumers/{string: group_name}/instances/{string: consumer_instance_id}/offsets        | Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.                               |
| GET         | /consumers/{string: group_name}/instances/{string: instance_id}/offsets                 | Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).                                                                 |
| POST        | /consumers/{string: group_name}/instances/{string: instance_id}/subscription            | Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription. |
| GET         | /consumers/{string: group_name}/instances/{string: instance_id}/subscription            | Gets the current subscribed list of topics.                                                                                                                                        |
| DELETE      | /consumers/{string: group_name}/instances/{string: instance_id}/subscription            | Unsubscribes from topics currently subscribed to.                                                                                                                                  |
| POST        | /consumers/{string: group_name}/instances/{string: instance_id}/assignments             | Manually assigns a list of partitions to a consumer.                                                                                                                               |
| GET         | /consumers/{string: group_name}/instances/{string: instance_id}/assignments             | Retrieves the list of partitions manually assigned to this consumer.                                                                                                               |
| POST        | /consumers/{string: group_name}/instances/{string: instance_id}/positions               | Overrides the fetch offsets that the consumer will use for the next set of records to fetch.                                                                                       |
| POST        | /consumers/{string: group_name}/instances/{string: instance_id}/positions/beginning     | Seek to the first offset for each of the given partitions.                                                                                                                         |
| POST        | /consumers/{string: group_name}/instances/{string: instance_id}/positions/end           | Seek to the last offset for each of the given partitions.                                                                                                                          |
| GET         | GET /consumers/{string: group_name}/instances/{string: instance_id}/records             | Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.                                                                                        |

| HTTP Method | URI                                                   | Description                                   |
|-------------|-------------------------------------------------------|-----------------------------------------------|
| GET         | <a href="#">/streams/{string: stream_name}/topics</a> | Retrieves a list of topics in a given stream. |

### API v1: Kafka REST Proxy Summary

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

 **Note:** Kafka REST 6.0.0.0 does not support API v1. Kafka REST 6.0.0.0 supports API v1 and v2 only.

| HTTP Method | URI                                                                                                            | Description                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| GET         | <a href="#">/topics</a>                                                                                        | Retrieves a list of topic names.                                                               |
| GET         | <a href="#">/topics/{topic: string}</a>                                                                        | Retrieves metadata about a specific topic.                                                     |
| POST        | <a href="#">/topics/{topic: string}</a>                                                                        | Produces a message into a topic.                                                               |
| GET         | <a href="#">/topics/{topic: string}/partitions</a>                                                             | Retrieves a list of partitions for the topic.                                                  |
| GET         | <a href="#">/topics/{topic: string}/partitions/{partition_id: string}</a>                                      | Retrieves metadata about specific partition in a topic.                                        |
| POST        | <a href="#">/topics/{topic: string}/partitions/{partition_id: string}</a>                                      | Produces messages to one partition of the topic.                                               |
| GET         | <a href="#">/topics/{topic: string}/partition/{partition_id: string}/messages?offset={int}&amp;count={int}</a> | Consumes messages from one partition of the topic.                                             |
| GET         | <a href="#">/stream/{stream: string}/topics</a>                                                                | Retrieves a list of topics in a given stream.                                                  |
| POST        | <a href="#">/consumers/{group: string}</a>                                                                     | Creates a new consumer instance in the consumer group.                                         |
| POST        | <a href="#">/consumers/{group: string}/instances/{instance: string}/offsets</a>                                | Commits offsets for the consumer. Returns a list of the partitions with the committed offsets. |
| DELETE      | <a href="#">/consumers/{group: string}/instances/{instance: string}</a>                                        | Destroys the consumer instance.                                                                |
| GET         | <a href="#">/consumers/{group: string}/instances/{instance: string}/topics/{topic: string}</a>                 | Consumes messages from a topic.                                                                |

### API v2 HTTP Methods and URIs

GET [/topics](#)  
Retrieves a list of topic names.

#### Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4078

#### Table

| Parameters Defined                             | Response                                                                                                |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined | Returns a list of topic names in the default stream.<br>Returns topic names that contain a stream path. |

Table (Continued)

| Parameters Defined                                 | Response                                                                                                                                                                                             |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is not defined | Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"} |

**Syntax**

```
http://<host>:8082/topics
```

**Request Example**

```
$ curl "Content-Type: application/vnd.kafka.v2+json" "http://localhost:8082/topics"
```

**Response Example**

```
[
 "streaming_data/stream:testtopic1",
 "streaming_data/stream:testtopic2"
]
```

GET /topics/{string: topic\_name}  
Retrieves metadata about a specific topic.

**Description**

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4078

Table

| Parameters Defined                                 | Response                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Gets metadata about a specific HPE Ezmeral Data Fabric Event Streams topic. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, <code>topic1</code> is equivalent to <code>default_stream:topic1</code> |
| <code>streams.default.stream</code> is not defined | Gets metadata about a specific HPE Ezmeral Data Fabric Event Streams topic. A fully qualified topic name is passed that contains the stream path.                                                                                                                                                                                |

**Note:** The full name for the HPE Ezmeral Data Fabric Event Streams topic contains characters such as a forward slash (/) and a colon (:), therefore, it should be encoded. For example, `/streaming_data/stream:topic-1` is equivalent to `%2Fstreaming_data%2Fstream%3Atopic-1`.

Table

| Parameters                       | Description                              |
|----------------------------------|------------------------------------------|
| <code>topic_name</code> (string) | Name of the topic to get metadata about. |

## Syntax

Syntax for a topic in a default stream where the default stream is configured:

```
http://<host>:8082/topics/<topic_string>
```

Syntax for a topic where the fully qualified topic name is specified:

```
http://<host>:8082/topics/%2F<streaming_data>%2F<stream>%3A<topic1>
```

## Request Example

```
curl "http://localhost:8082/topics/test"
```

## Response Example

```
{
 "name": "test",
 "configs": null,
 "partitions":
 [
 {
 "partition": 0,
 "leader": 0,
 "replicas":
 [
 {"broker": 0, "leader": true, "in_sync": true},
 {"broker": 0, "leader": false, "in_sync": true}
]
 }
]
}
```

POST /topics/{string: topic\_name}  
Produces messages to a topic.

## Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4078

### Table

| Parameters Defined                                 | Response                                                                                                                                                              |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Produces messages into specific HPE Ezmeral Data Fabric Event Streams topics. If the topic name does not contain a stream path, then the default stream path is used. |
| <code>streams.default.stream</code> is not defined | Produces messages into a HPE Ezmeral Data Fabric Event Streams topic. The topic name should contain a stream path and be encoded.                                     |

**Note:** If the topic does not exist, the following error results: [{"error\_code":40401, "message": "Topic not found."}]. New topics are not created by the POST operation.

### Table

| Parameters                                | Description                                   |
|-------------------------------------------|-----------------------------------------------|
| <code>topic_name</code> ( <i>string</i> ) | Name of the topic to produce the messages to. |

## Syntax

```
http://<host>:8082/topics/<topic_string>
```

## Request Example

This example produces a message using binary embedded data with the value, Kafka, to the topic, test.

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2" --data
'{"records":[{"value":"S2Fma2E="}]}' "http://localhost:8082/topics/test"
```

## Response Example

```
{
 "offsets":
 [
 {
 "partition": 0,
 "offset": 1,
 "error_code": null,
 "error": null
 }
],
 "key_schema_id": null,
 "value_schema_id": null
}
```

GET /topics/{string: topic\_name}/partitions  
Retrieves a list of partitions for the topic.

## Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4078.

Table

| Parameters Defined                                 | Response                                                                                                                                                                                                                                                         |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Gets metadata about specific HPE Ezmeral Data Fabric Event Streams partitions within a topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path. |
| <code>streams.default.stream</code> is not defined | Gets metadata about specific HPE Ezmeral Data Fabric Event Streams partitions within topic. The user could only pass fully qualified topic name that contains stream path.                                                                                       |

Table

| Parameters                                | Description        |
|-------------------------------------------|--------------------|
| <code>topic_name</code> ( <i>string</i> ) | Name of the topic. |

## Syntax

```
http://<host>:8082/topics/<topic_name>/partitions
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
"http://localhost:8082/topics/testtopic1/partitions"
```

### Response Example

```
[
 {
 "partition":0,
 "leader":0,
 "replicas":
 [{
 "broker":0,
 "leader":true,
 "in_sync":true
 }]
 },
 {
 "partition":1,
 "leader":0,
 "replicas":
 [{
 "broker":0,
 "leader":true,
 "in_sync":true
 }]
 }
]
```

GET /topics/{string: topic\_name}/partitions/{string: partition\_id}  
 Retrieves metadata about a specific partition within a topic.

### Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4078.

Table

| Parameters Defined                                 | Response                                                                                                                                                                                                                                                          |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Gets metadata about a specific partition within a HPE Ezmeral Data Fabric Event Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path. |
| <code>streams.default.stream</code> is not defined | Gets metadata about specific HPE Ezmeral Data Fabric Event Streams partitions within a topic. The user could only pass fully qualified topic names that contains stream path.                                                                                     |

Table

| Parameters                                | Description                     |
|-------------------------------------------|---------------------------------|
| <code>topic_name</code> ( <i>string</i> ) | Name of the topic.              |
| <code>partition_id</code> ( <i>int</i> )  | ID of the partition to inspect. |

### Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/
partitions/0
```

### Response Example

```
{
 "partition":0,
 "leader":0,
 "replicas":
 [{
 "broker":0,
 "leader":true,
 "in_sync":true
 }]
}
```

GET /topics/{string: topic\_name}/partitions/{string: partition\_id}/offsets

Returns a summary with beginning and end offsets for the given topic and specific partition.

### Description

Information retrieved varies depending on the configuration. See the `streams.default.stream` in [Configuration Parameters](#) on page 4078.

#### Table

| Parameters Defined                                 | Response                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Gets summary with beginning and end offsets for the specific partition of the HPE Ezmeral Data Fabric Event Streams topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path. |
| <code>streams.default.stream</code> is not defined | Gets summary with beginning and end offsets for the specific HPE Ezmeral Data Fabric Event Streams partition within a topic. You can only pass the fully qualified topic names that contain the stream path.                                                                             |

#### Table

| Parameter                                 | Description                     |
|-------------------------------------------|---------------------------------|
| <code>topic_name</code> ( <i>string</i> ) | Name of the topic.              |
| <code>partition_id</code> ( <i>int</i> )  | ID of the partition to inspect. |

### Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>/offsets
```

### Request Example

```
curl -X GET -H "Content-Type:
application/vnd.kafka.v2" http://localhost:8082/topics/
%2Fstreaming_data%2Fstream%3Atesttopic1/partitions/0/offsets
```

## Response Example

```
{
 "beginning_offset":0,
 "end_offset":0
}
```

POST /topics/{string: topic\_name}/partitions/{string: partition\_id}

Produces messages into a partition of a topic.

## Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4078.

## Table

| Parameters Defined                                 | Response                                                                                                                                                                                                                                             |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Produces messages into a partition of HPE Ezmeral Data Fabric Event Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, messages are produced into topics in the default stream path. |
| <code>streams.default.stream</code> is not defined | Produces messages into a partition within HPE Ezmeral Data Fabric Event Streams topic. The user could only pass fully qualified topic name that contains stream path.                                                                                |

## Table

| Parameters                                | Description                           |
|-------------------------------------------|---------------------------------------|
| <code>topic_name</code> ( <i>string</i> ) | Topic to produce the messages to.     |
| <code>partition_id</code> ( <i>int</i> )  | Partition to produce the messages to. |

## Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2+json" --data
'{"records":[{"key":"a2v5","value":"Y29uZmx1ZW50"}]}'
"http://localhost:8082/topics/testtopic1/partitions/0"
```

## Response Example

```
{
 "offsets":
 [{
 "partition":0,
 "offset":1,
 "error_code":null,"error":null}
],
 "key_schema_id":null,
 "value_schema_id":null
}
```

POST /consumers/{string: group\_name}

Creates a new consumer instance in the consumer group.

## Description

Table

| Parameters                                  | Description                                                                                                                                                                                                                                                                                |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>group_name</b> ( <i>string</i> )         | The name of the consumer group to join.                                                                                                                                                                                                                                                    |
| <b>name</b> ( <i>string</i> )               | Name for the consumer instance, which will be used in URLs for the consumer. This must be unique, at least within the proxy process handling the request. If omitted, falls back on the automatically generated ID. Using automatically generated names is recommended for most use cases. |
| <b>format</b> ( <i>string</i> )             | The format of consumed messages, which is used to convert messages into a JSON-compatible form. Valid values: "binary", "avro", "json". If unspecified, defaults to "binary".                                                                                                              |
| <b>auto.offset.reset</b> ( <i>string</i> )  | Sets the <b>auto.offset.reset</b> setting for the consumer. Values: latest, earliest, none                                                                                                                                                                                                 |
| <b>auto.commit.enable</b> ( <i>string</i> ) | Sets the <b>auto.commit.enable</b> setting for the consumer.                                                                                                                                                                                                                               |

**Note:** You cannot set the time-to-live (TTL) for consumer instances or consumer groups. However, consumers can be configured to be deleted after some idle time. The amount of idle time before a consumer instance is automatically destroyed is set by the `consumer.instance.timeout.ms` property in the **kafka-rest.properties** file. See [Configuration Parameters](#) on page 4078.

## Syntax

```
http://<host>:8082/consumers/<group_name>
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json"
--data '{"name":"user","format":"binary","auto.offset.reset":
"earliest"}'
http://localhost:8082/consumers/groupptest
```

## Response Example

The response JSON object is in the following form:

- **instance\_id** (*string*) – Unique ID for the consumer instance in this group. The `instance_id` is automatically generated if the `name` parameter is not specified.
- **base\_uri** (*string*) – Base URI used to construct URIs for subsequent requests against this consumer instance. This will be of the form `http://hostname:port/consumers/consumer_group/instances/instance_id`.

```
{
 "instance_id": "user",
 "base_uri": "http://localhost:8082/consumers/groupptest/instances/
user"
}
```

DELETE /consumers/{string: group\_name}/instances/{string: instance\_id}  
Destroys the consumer instance.

## Description

The request must be made to the specific REST proxy instance holding the consumer instance.

### Table

| Parameters                          | Description                     |
|-------------------------------------|---------------------------------|
| <b>group_name</b> ( <i>string</i> ) | The name of the consumer group. |
| <b>instance</b> ( <i>string</i> )   | The ID of the consumer instance |

## Syntax

```
http://<host>:8082/topics/<group_name>/instances/<instance_string>
```

## Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/consumers/my_binary_consumer/instances/
rest-consumer-11561681-
8ba5-4b46-bed0-905ae1769bc6
```

## Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: consumer\_instance\_id}/offsets

Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.

## Parameters

### Table

| Parameters                                 | Description                                 |
|--------------------------------------------|---------------------------------------------|
| <b>group_name</b> ( <i>string</i> )        | The name of the consumer group.             |
| <b>instance_id</b> ( <i>string</i> )       | The ID of the consumer instance.            |
| <b>offsets</b>                             | A list of offsets to commit for partitions. |
| <b>offsets[i].topic</b> ( <i>string</i> )  | Name of the topic                           |
| <b>offsets[i].partition</b> ( <i>int</i> ) | Partition ID                                |
| <b>offset</b>                              | The offset to commit.                       |

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_instance_id>/
offsets
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic":
"/mystream:first", "partition": 0, "offset": 5}]}'
https://node2:8082/consumers/groupptest/instances/user/offsets
```

## Response Example

```
HTTP/1.1 200 OK
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/offsets

Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).

## Parameters

Table

| Parameter                                     | Description                                              |
|-----------------------------------------------|----------------------------------------------------------|
| <b>group_name</b> ( <i>string</i> )           | Name of the consumer group.                              |
| <b>instance</b> ( <i>string</i> )             | ID of the consumer instance.                             |
| <b>partitions</b>                             | A list of partitions to find the last committed offsets. |
| <b>partitions[i].topic</b> ( <i>string</i> )  | Name of the topic.                                       |
| <b>partitions[i].partition</b> ( <i>int</i> ) | Partition ID                                             |

## Syntax

```
http://localhost:8082/consumers/<group_name>/instances/<consumer_name>/offsets
```

## Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.binary.v2+json" --data '{"partitions":[{"topic":"/stream:topic","partition":0}]}' https://node2:8082/consumers/groupptest/instances/user/offsets
```

## Response Example

The response JSON object is in the following form:

- offsets - A list of committed offsets.
- offsets[i].topic (string) – Name of the topic for which an offset was committed
- offsets[i].partition (int) – Partition ID for which an offset was committed
- offsets[i].offset (int) – Committed offset
- offsets[i].metadata (string) – Metadata for the committed offset

```
{ "offsets" :
 [
 {
 "topic": "/stream:topic",
 "partition": 0,
 "offset": 21,
 "metadata": ""
 }
]
}
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/subscription

Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.

### Parameters

Table

| Parameter                    | Description                  |
|------------------------------|------------------------------|
| group_name ( <i>string</i> ) | Name of the consumer group.  |
| instance ( <i>string</i> )   | ID of the consumer instance. |

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/subscription
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data '{"topics":["/stream:first","/stream:second"]}' https://localhost:8082/consumers/groupptest/instances/user/subscription
```

### Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/subscription

Gets the current subscribed list of topics.

### Parameters

Table

| Parameter                    | Description                  |
|------------------------------|------------------------------|
| group_name ( <i>string</i> ) | Name of the consumer group.  |
| instance ( <i>string</i> )   | ID of the consumer instance. |

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/subscription
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json" https://localhost:8082/consumers/groupptest/instances/user/subscription
```

### Response Example

The response JSON object is in the following form:

- topics – A list of subscribed topics

- topics[i] (string) – Name of the topic

```
{
 "topics": [
 "/stream:first",
 "/stream:second"
]
}
```

DELETE /consumers/{string: group\_name}/instances/{string: instance\_id}/subscription  
Unsubscribes from topics currently subscribed to.

### Parameters

#### Table

| Parameter                           | Description                  |
|-------------------------------------|------------------------------|
| <b>group_name</b> ( <i>string</i> ) | Name of the consumer group.  |
| <b>instance</b> ( <i>string</i> )   | ID of the consumer instance. |

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/subscription
```

### Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

### Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/assignments  
Manually assigns a list of partitions to a consumer.

### Parameters

#### Table

| Parameter                           | Description                  |
|-------------------------------------|------------------------------|
| <b>group_name</b> ( <i>string</i> ) | Name of the consumer group.  |
| <b>instance</b> ( <i>string</i> )   | ID of the consumer instance. |

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/assignments
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions":[{"topic":"first","partition":0}]}'
https://localhost:8082/consumers/groupptest/instances/user/assignments
```

## Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/assignments  
Retrieves the list of partitions currently assigned to this consumer.

## Parameters

### Table

| Parameter                           | Description                  |
|-------------------------------------|------------------------------|
| <b>group_name</b> ( <i>string</i> ) | Name of the consumer group.  |
| <b>instance</b> ( <i>string</i> )   | ID of the consumer instance. |

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

## Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/assignments
```

## Response Example

The response JSON object is in the following form:

- partitions – A list of partitions assigned to this consumer.
- partitions[i].topic (*string*) – Name of the topic.
- partitions[i].partition (*int*) – Partition ID

```
{
 "partitions": [
 {
 "topic": "test",
 "partition": 0
 },
 {
 "topic": "test",
 "partition": 1
 }
]
}
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions  
Overrides the fetch offsets that the consumer will use for the next set of records to fetch.

## Parameters

### Table

| Parameter                                  | Description                                          |
|--------------------------------------------|------------------------------------------------------|
| <b>group_name</b> ( <i>string</i> )        | Name of the consumer group.                          |
| <b>instance</b> ( <i>string</i> )          | ID of the consumer instance.                         |
| <b>offsets</b>                             | A list of offsets                                    |
| <b>offsets[i].topic</b> ( <i>string</i> )  | Name of the topic                                    |
| <b>offsets[i].partition</b> ( <i>int</i> ) | Partition ID                                         |
| <b>offsets[i].offset</b> ( <i>int</i> )    | Seek to offset for the next set of records to fetch. |

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/positions
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data '{"offsets": [{"topic": "/stream:first", "partition": 0, "offset": 3}]}' https://localhost:8082/consumers/groupptest/instances/user/positions
```

### Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions/beginning  
Seek to the first offset for each of the given partitions.

## Parameters

### Table

| Parameter                                     | Description                  |
|-----------------------------------------------|------------------------------|
| <b>group_name</b> ( <i>string</i> )           | Name of the consumer group.  |
| <b>instance</b> ( <i>string</i> )             | ID of the consumer instance. |
| <b>partitions</b>                             | A list of partitions.        |
| <b>partitions[i].topic</b> ( <i>string</i> )  | Name of the topic            |
| <b>partitions[i].partition</b> ( <i>int</i> ) | Partition ID                 |

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/positions/beginning
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data '{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
```

```
https://localhost:8082/consumers/groupptest/instances/user/positions/
beginning
```

### Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions/end  
Seek to the last offset for each of the given partitions.

### Parameters

#### Table

| Parameter                                     | Description                  |
|-----------------------------------------------|------------------------------|
| <b>group_name</b> ( <i>string</i> )           | Name of the consumer group.  |
| <b>instance</b> ( <i>string</i> )             | ID of the consumer instance. |
| <b>partitions</b>                             | A list of partitions.        |
| <b>partitions[i].topic</b> ( <i>string</i> )  | Name of the topic            |
| <b>partitions[i].partition</b> ( <i>int</i> ) | Partition ID                 |

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/end
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
https://localhost:8082/consumers/groupptest/instances/user/positions/end
```

### Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/records  
Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.

### Parameters

The format of the embedded data returned by this request is determined by the format specified in the initial consumer instance creation request and must match the format of the Accept header.

**Note:** This request *must* be made to the specific REST proxy instance holding the consumer instance.

#### Table

| Parameter                           | Description                  |
|-------------------------------------|------------------------------|
| <b>group_name</b> ( <i>string</i> ) | Name of the consumer group.  |
| <b>instance</b> ( <i>string</i> )   | ID of the consumer instance. |

Table (Continued)

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timeout</b>   | The number of milliseconds for the underlying client library poll(timeout) request to fetch the records. Default: 5000ms.                                                                                                                                                                                                                                        |
| <b>max_bytes</b> | The maximum number of bytes of unencoded keys and values that should be included in the response. This provides approximate control over the size of responses and the amount of memory required to store the decoded response. The actual limit is the minimum of this setting and the server-side configuration consumer.request.max.bytes. Default: unlimited |

**Syntax**

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/records
```

**Request Example**

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/records
```

**Response Example**

```
[
 {
 "topic": "test",
 "key": "a2V5",
 "value": "Y29uZmx1ZW50",
 "partition": 1,
 "offset": 100,
 },
 {
 "topic": "test",
 "key": "a2V5",
 "value": "a2Fma2E=",
 "partition": 2,
 "offset": 101,
 }
]
```

GET /streams/{string: stream\_name}/topics  
Retrieves a list of topics in a given stream.

**Description**

Stream names contain characters such as backslashes (/) and colons (:), and, therefore, should be encoded.

Table

| Parameters                           | Description             |
|--------------------------------------|-------------------------|
| <b>stream_name</b> ( <i>string</i> ) | The name of the stream. |

**Syntax**

```
http://<host>:8082/streams/<stream_name>/topics
```

**Request Example**

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/streams/%2Fstreaming_data%2Fstream/topics
```

**Response Example**

```
[
 "/streaming_data/stream:testtopic1",
 "/streaming_data/stream:testtopic2"
]
```

**API v3 HTTP Methods and URIs****GET /v3/clusters**

Retrieves a list of metadata about the cluster.

**Description**

Retrieves one cluster only. Always retrieves the current HPE Ezmeral Data Fabric cluster.

**Syntax**

```
http://<host>:8082/v3/clusters
```

**Request Example**

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/
clusters
```

**Response Example**

```
{
 "kind": "KafkaClusterList",
 "metadata":
 {
 "self": "http://node1.cluster.com:8082/v3/clusters",
 "next": null
 },
 "data":

}
}

```

GET /v3/clusters/{string: cluster\_id}/topics  
 Retrieves a list of topic names on the specific cluster.

**Description**

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4078.

Table

| Parameters Defined                                 | Response                                                                                                                                                                                                   |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Returns a list of topic names and metadata in the default stream. Returns topic names and metadata that contains a stream path.                                                                            |
| <code>streams.default.stream</code> is not defined | Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}. |

Table

| Parameters                                | Description   |
|-------------------------------------------|---------------|
| <code>cluster_id</code> ( <i>string</i> ) | Cluster's id. |

## Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

## Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics"
```

## Response Example

```
{

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}  
 Retrieves metadata about a specific topic within a cluster.

**Description**

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4078.

**Table**

| Parameters Defined                                 | Response                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Gets metadata about a specific HPE Ezmeral Data Fabric Event Streams topic on this cluster. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, <code>topic1</code> is equivalent to <code>default_stream:topic1</code> . |
| <code>streams.default.stream</code> is not defined | Gets metadata about a specific HPE Ezmeral Data Fabric Event Streams topic on this cluster. A fully qualified topic name is passed that contains the stream path.                                                                                                                                                                                  |

 **Note:** The full name for the HPE Ezmeral Data Fabric Event Streams topic contains characters such as a forward slash (/) and a colon (:). Therefore, the topic should be encoded. For example, `/streaming_data/stream:topic-1` is equivalent to `%2Fstreaming_data%2Fstream%3Atopic-1`.

**Table**

| Parameters                                | Description        |
|-------------------------------------------|--------------------|
| <code>cluster_id</code> ( <i>string</i> ) | Cluster's id.      |
| <code>topic_name</code> ( <i>string</i> ) | Name of the topic. |

**Syntax**

```

http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>

```

### Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics/tp-2"
```

### Response Example

```
{
 "kind": "KafkaTopic",
 "metadata": {
 {
 "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2",

 }
 }
 }
 }
 }
}
```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions  
Retrieves a list of partitions for the topic within a cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4078.

Table

| Parameters Defined                                 | Response                                                                                                                                                                                                                                                                         |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Gets metadata about specific HPE Ezmeral Data Fabric Event Streams partitions within a topic on this cluster. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path. |
| <code>streams.default.stream</code> is not defined | Gets metadata about specific HPE Ezmeral Data Fabric Event Streams partitions within topic on this cluster. The user could only pass fully qualified topic name that contains stream path.                                                                                       |

Table

| Parameters                          | Description        |
|-------------------------------------|--------------------|
| <b>cluster_id</b> ( <i>string</i> ) | Cluster's id.      |
| <b>topic_name</b> ( <i>string</i> ) | Name of the topic. |

### Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions
```

### Request Example

```

 }
]
 }
 }
}

```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions/{string: partition\_id}/replicas/{string: broker\_id}

Retrieves metadata about a specific replica within a partition, a topic, and a cluster.

**Description**

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4078.

**Table**

| Parameters Defined                                 | Response                                                                                                                                                                                                                                                                 |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Gets metadata about specific broker of the HPE Ezmeral Data Fabric Event Streams partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path. |
| <code>streams.default.stream</code> is not defined | Gets metadata about specific broker of the HPE Ezmeral Data Fabric Event Streams partition within a topic. The user could only pass fully qualified topic name that contains stream path.                                                                                |

**Table**

| Parameters                                | Description                     |
|-------------------------------------------|---------------------------------|
| <code>cluster_id</code> ( <i>string</i> ) | Cluster's id.                   |
| <code>topic_name</code> ( <i>string</i> ) | Name of the topic.              |
| <code>partition_id</code> ( <i>int</i> )  | ID of the partition to inspect. |
| <code>broker_id</code> ( <i>int</i> )     | ID of the broker to inspect.    |

**Syntax**

```

http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas/<broker_id>

```

### Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics/tp-2/partitions/1/replicas/0"
```

### Response Example

```
{
 "kind": "KafkaReplica",
 "metadata": {

```

POST /v3/clusters/{string: cluster\_id}/topics  
Creates a new topic on the specific cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4078

#### Table

| Parameters Defined                                 | Response                                                                                                                                                                                                   |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Creates a topic in the default stream and returns its metadata.                                                                                                                                            |
| <code>streams.default.stream</code> is not defined | Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}. |

#### Table

| Parameters                                | Description   |
|-------------------------------------------|---------------|
| <code>cluster_id</code> ( <i>string</i> ) | Cluster's id. |

### Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

### Request Example

```
$ curl -X POST -H "Content-Type: application/json" --data '{"topic_name": "new-topic", "partitions_count": 4}' "http://localhost:8082/v3/clusters/682798077049224619/topics"
```

### Request Response

```
{
 "kind": "KafkaTopic",

 }
 }
 }
 }
 }
}
```

**DELETE /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}**  
 Deletes a topic from the specific cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4078.

**Table**

| Parameters Defined                                 | Response                                                                                                                                                                                                   |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>streams.default.stream</code> is defined     | Deletes topic from the default stream.                                                                                                                                                                     |
| <code>streams.default.stream</code> is not defined | Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}. |

**Table**

| Parameters                                | Description        |
|-------------------------------------------|--------------------|
| <code>cluster_id</code> ( <i>string</i> ) | Cluster's id.      |
| <code>topic_name</code> ( <i>string</i> ) | Name of the topic. |

## Syntax

```
http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>
```

## Request Example

```
$ curl -X DELETE -H "Content-Type: application/json" "http://
localhost:8082/v3/clusters/682798077049224619/topics/new-topic"
```

## Response Example

```
HTTP/1.1 204 No Content
```

## Kafka Connect

Kafka Connect is a utility for streaming data between HPE Ezmeral Data Fabric Event Streams and other storage systems.

Examples of other systems include:

- Relational databases
- Logs and metrics
- Hadoop and data warehouses
- NoSQL data stores

Kafka Connect makes it easy to integrate all your data via Kafka, making it available as realtime streams. For example, you can use Kafka Connect to:

- Stream changes from a relational database to make events available with low latency for stream processing applications.
- Import realtime logs and metrics into HPE Ezmeral Data Fabric Event Streams and process them to detect anomalies.
- Implement a process of loading data into HPE Ezmeral Data Fabric Event Streams from your primary data storage systems, performing filtering, transformations, and enrichment with a stream processing framework, and publish the data to the HPE Ezmeral Data Fabric File Store.

**Note:** Built-in security is not available.

## Architecture of Kafka Connect

Kafka Connect for HPE Ezmeral Data Fabric Event Streams has the following major models in its design: connector, worker, and data.

### Connector Model

A connector is defined by specifying a Connector class and configuration options to control what data is copied and how to format it.

- Each Connector instance is responsible for defining and updating a set of Tasks that actually copy the data.
- Kafka Connect manages the Tasks; the Connector is only responsible for generating the set of Tasks and indicating to the framework when they need to be updated.

- Source and Sink Connectors/Tasks are distinguished in the API to ensure the simplest possible API for both.

There are two types of tasks:

- **Source** - Source tasks ingest data from data storage systems and stream the data to HPE Ezmeral Data Fabric Event Streams.
- **Sink** - Sink tasks stream data from HPE Ezmeral Data Fabric Event Streams to other storage systems.

HPE Ezmeral Data Fabric supports the following connectors:

- JDBC Source Connector

The Kafka JDBC source connector is a type connector used to stream data from relational databases into HPE Ezmeral Data Fabric Event Streams topics. JDBC Source Connector for HPE Ezmeral Data Fabric Event Streams supports integration with Hive 2.1.

- JDBC Sink Connector

The Kafka JDBC sink connector is a type connector used to stream data from HPE Ezmeral Data Fabric Event Streams topics to relational databases that have a JDBC driver.

- HDFS Sink Connector

The Kafka HDFS sink connector is a type connector used to stream data from HPE Ezmeral Data Fabric Event Streams to filesystem. By default, the resulting data is produced to filesystem in Avro format. In addition, Parquet files can be written to filesystem.

### Worker Model

A Kafka Connect for HPE Ezmeral Data Fabric Event Streams cluster consists of a set of Worker processes that are containers that execute Connectors and Tasks. A worker is a JVM process with a REST API that is able to execute streaming tasks.

- Workers automatically coordinate with each other to distribute work and provide scalability and fault tolerance.
- The Workers distribute work among any available processes, but are not responsible for management of the processes;
- Any process management strategy can be used for Workers. For example, cluster management tools like YARN or Mesos, configuration management tools like Chef or Puppet, or direct management of process lifecycles.

### Data Model

Connectors copy streams of messages from a partitioned input stream to a partitioned output stream, where at least one of the input or output is *always* Kafka.

- Each of these streams is an ordered set messages where each message has an associated offset.
- The format and semantics of these offsets are defined by the Connector to support integration with a wide variety of systems; however, to achieve certain delivery semantics in the face of faults requires that offsets are unique within a stream and streams can seek to arbitrary offsets.
- Message contents are represented by Connectors in a serialization-agnostic format.
- Pluggable Converters are available for storing this data in a variety of serialization formats.

- Schemas are built-in, allowing important metadata about the format of messages to be propagated through complex data pipelines. However, schema-free data can also be use when a schema is simply unavailable.

### Connectors, Tasks, and Workers

Describes how Kafka Connect for HPE Ezmeral Data Fabric Event Streams works and how connectors, tasks, offsets, and workers are associated.

#### Connectors

Connectors (or a **connector instance**) are logical jobs that are responsible for managing the copying of data between HPE Ezmeral Data Fabric Event Streams and another systems. Each connector instantiates a set of **tasks** that copies the data. By allowing the connector to break a single job into many tasks, support is built-in for parallelism and scalable data copying with very little configuration. **Connector plugins** are jars that add the classes that implement a connector.

#### Offsets

As connectors run, Kafka Connect tracks **offsets** for each one so that connectors can resume from their previous position in the event of failures or graceful restarts for maintenance. They track the current position in the stream of data being copied and because each connector may need to track many offsets for different **partitions** of the stream. For example, when loading data from a database, the offset might be a transaction ID that identifies a position in the database change log.

Users generally do not need to worry about the format of offsets, especially since they differ from connector to connector. However, Kafka Connect does require persistent storage for offset data to ensure it can recover from faults. This storage for offset data is configurable. See [Standalone Worker Configuration Options](#) on page 4125 and [Distributed Worker Configuration Options](#) on page 4125.

#### Workers

Connectors and tasks are logical units of work and must be scheduled to execute in a process. Kafka Connect calls these processes **workers**. With Kafka Connect for MapR streams, the worker processors run as a service. This service can be run in either standalone mode or distributed mode.

- In standalone mode, the cluster consists of a single worker that is supplied with tasks that are useful for testing and debugging purposes.
- In distributed mode, the cluster consisting from multiple workers with the same group.id, offset.storage.topic, and config.storage.topic. Connector tasks are submitted via the Kafka Connect REST API.

The following list the location of the standalone and distributed worker configuration files:

```
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**Note:** Distributed mode is supported on MapR 5.2.1 and above

**Note:** Port 8083 is the default port.

**Note:** If you running multiple workers on the same node, the rest.port parameter must be different for each worker.

#### *Configuring in Standalone Mode*

The section describes how to configure and execute workers in Kafka connect standalone mode.

Standalone mode is the simplest mode, where a single process is responsible for executing all connectors and tasks. Since it is a single process, it requires minimal configuration.

Configuring and running in standalone mode, involves configuring the standalone properties and connector parameters before executing the standalone shell command along with the properties files on the command line.

The following parameters must be provided in the **connect-standalone.properties** file.

- `offset.storage.file.filename` - Storage for connector offsets which are stored on the local filesystem in standalone mode. Using the same file leads to offset data being deleted or overwritten with different values.
- `rest.port` - Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this parameter must have different values for each instance.

**Note:** If you are running multiple standalone instances on the same host, these parameters must be different for each instances. Therefore, an additional properties file is created for the instance with different parameter values.

To run a worker in standalone mode:

1. Edit the **./config/connect-standalone.properties** file and add the name of the local file that will store the connector offsets.
2. Edit the **quickstart-sqlite.properties** file (JDBC connector configuration file).
3. Run the **./bin/connect-standalone.sh** command along with the properties files on the command line.

For example:

```
cd /opt/mapr/kafka/kafka-<version>
./bin/connect-standalone.sh
./config/connect-standalone.properties
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
```

The first parameter is always a configuration file for the worker. This configuration gives you control over settings such as which cluster to use and the serialization format. See [JDBC Connector](#) on page 4130 for more information. All additional parameters should be connector configuration files. Each file contains a single connector configuration.

### *Configuring in Distributed Mode*

This section describes how to configure and run workers in Kafka Connect distributed mode.

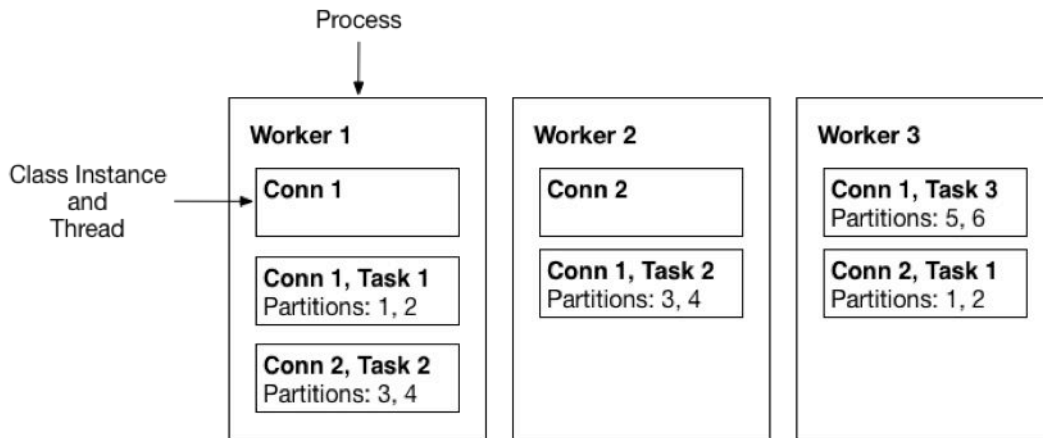

Distributed mode provides scalability and automatic fault tolerance for Kafka Connect. In distributed mode, multiple worker processes are started using the same `group.id`. These processes automatically coordinate to schedule execution of connectors and tasks across all available workers. If a worker is added, shuts down, or fails unexpectedly, the rest of the workers detect this and automatically coordinate to redistribute connectors and tasks across the updated set of available workers.

**Note:** Distributed mode is available as of EEP 2.0.1.

The following diagrams illustrates a three-node Kafka Connect distributed mode cluster where:

- Connectors are monitoring the source or sink system for changes that require reconfiguring tasks.
- Tasks are automatically balanced across the active workers by copying a subset of a connector's data.
- The division of work between tasks is shown by the partitions that each task is assigned.

Interaction with a distributed-mode cluster is via the REST API (rather than on the command line). To create a connector, the workers are started and then REST request is made to create a connector. See [REST API](#) on page 4146.

 **Note:** Kafka Connect workers do not have a special “leader” process that you have to interact with to use the REST API. All nodes can respond to REST requests, including creating, listing, modifying, and destroying connectors.

To run the worker in distributed mode:

1. In the `connect-distributed.properties` file, define the topics that will store the connector state, task configuration state, and connector offset state.

In distributed mode, the workers need to be able to discover each other and have shared storage for connector configuration and offset data. In addition to the usual worker settings, ensure you have configured the following for the cluster:

- **group.id** - ID that uniquely identifies the cluster these workers belong to. Ensure this is unique for all groups that work with a cluster.
  - **config.storage.topic** - Topic to store the connector and task configuration state in. Although this topic can be auto-created if your cluster has auto topic creation enabled, it is highly recommended that you create it before starting the cluster. This topic should **always** have a single partition and be highly replicated (3x or more).
  - **offset.storage.topic** - Topic to store the connector offset state in. To support large HPE Ezmeral Data Fabric Event Streams clusters, this topic should have a large number of partitions (for example, 25 or 50 partitions and highly replicated (3x or more)).
  - **rest.port** - Port where the REST interface listens for HTTP requests. If you run more than one worker per host (for example, if you are testing distributed mode locally during development), this setting must have different values for each instance.
2. Set the `group.id` value for all of the workers in the cluster.

**Note:** All workers that belong to the same cluster must have the same `group.id` value.

3. Start the Kafka Connect service in distributed mode:

```
maprcli node services -name kafka-connect -action start -nodes
<node_list>
```

For more information, see [Managing Kafka Connect Services](#) on page 4140.

**Note:** >Distributed mode does not have any additional command line parameters. If other instances are already running, new workers either start a new group or join an existing one, and then wait for work to do. For information on managing the connectors running in the cluster, see [REST API](#) on page 4146.

### Connector Configuration

This section describes how and where connectors are configured.

Connector configurations are key-value mappings. For standalone mode, these parameters are defined in a properties file and passed to the Connect process on the command line. In distributed mode, they will be included in the JSON payload for the request that creates (or modifies) the connector. Most configurations are connector dependent, but there are a few settings common to all connectors:

- `name` - Unique name for the connector. Attempting to register again with the same name will fail.
- `connector.class` - The Java class for the connector
- `tasks.max` - The maximum number of tasks that should be created for this connector. The connector may create fewer tasks if it cannot achieve this level of parallelism.

Sink connectors also have one additional option to control their input:

- `topics` - A list of topics to use as input for this connector

For other options, consult the documentation for the JDBC and HDFS connectors. See [JDBC Connector](#) on page 4130 and [HDFS Connector](#) on page 4140.

### Worker Configuration

This section describes how and where to configure workers.

Whether you're running standalone or distributed mode, Kafka Connect workers are configured by passing a properties file containing any required or overridden options as the first parameter to the worker process.

#### *Common Worker Configuration Options*

You can set common worker configuration options for standalone or distributed mode in the `connect-<standalone/distributed>.properties` file. The options control basic functionality, including which cluster to communicate with and data format.

### Setting the Schema Registry URL for the Avro Converter

Set the Schema Registry URL for the converter through the following properties:

- `key.converter.schema.registry.url=<URL:PORT>`
- `value.converter.schema.registry.url=<URL:PORT>`
- For Avro, use `io.confluent.connect.avro.AvroConverter`.
- For Protobuf, use `io.confluent.connect.protobuf.ProtobufConverter`.
- For JSON Schema, use `io.confluent.connect.json.JsonSchemaConverter`.

If you do not set these properties, the Schema Registry URL is taken from ZooKeeper.

The following table describes the common worker configuration parameters:

| Parameter                        | Description                                                                                                                                                                                                                                                                                                  |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>plugin.path</b>               | The comma-separated list of paths to directories that contain Kafka Connect plugins. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: empty</li> </ul>                                                                                                                                  |
| <b>key.converter</b>             | Converter class for key Connect data. This controls the format of the data that will be written to HPE Ezmeral Data Fabric Event Streams for source connectors or read from MapR Streams for sink connectors. <ul style="list-style-type: none"> <li>Type: class</li> <li>Default: empty</li> </ul>          |
| <b>value.converter</b>           | Converter class for value Connect data. This controls the format of the data that will be written to HPE Ezmeral Data Fabric Event Streams for source connectors or read from MapR Streams for sink connectors. <ul style="list-style-type: none"> <li>Type: class</li> <li>Default: empty</li> </ul>        |
| <b>internal.key.converter</b>    | Converter class for internal key Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> <li>Type: class</li> <li>Default:</li> </ul>                                                                                    |
| <b>internal.value.converter</b>  | Converter class for offset value Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> <li>Type: class</li> <li>Default:</li> </ul>                                                                                    |
| <b>offset.flush.interval.ms</b>  | Interval (milliseconds) at which to try committing offsets for tasks. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 60000</li> </ul>                                                                                                                                                   |
| <b>offset.flush.timeout.ms</b>   | Maximum number of milliseconds to wait for records to flush and partition offset data to be committed to offset storage before cancelling the process and restoring the offset data to be committed in a future attempt. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000</li> </ul> |
| <b>rest.advertised.host.name</b> | If set, this is the hostname that will be given out to other workers to connect to. <ul style="list-style-type: none"> <li>Type: string</li> </ul>                                                                                                                                                           |
| <b>rest.advertised.port</b>      | If set, this is the port that will be given out to other workers to connect to. <ul style="list-style-type: none"> <li>Type: int</li> </ul>                                                                                                                                                                  |

| Parameter                                       | Description                                                                                                                                                                                                                                                                         |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rest.host.name</b>                           | Hostname for the REST API. If this is set, it will only bind to this interface. <ul style="list-style-type: none"> <li>Type: string</li> </ul>                                                                                                                                      |
| <b>rest.port</b>                                | Port for the REST API to listen on. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 8083</li> </ul>                                                                                                                                                              |
| <b>task.shutdown.graceful.timeout.ms</b>        | Amount of time to wait (milliseconds) for tasks to shutdown gracefully. This is the total amount of time, not per task. All task have shutdown triggered, then they are waited on sequentially. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000</li> </ul> |
| <b>streams.consumer.streams.default.stream</b>  | If set, topic names can be used in the Sink task configuration without the stream name. The defined default stream is used.                                                                                                                                                         |
| <b>streams.producer.producer.default.stream</b> | If set, topic names can be used in the Source task configuration without the stream name. The defined default stream is used.                                                                                                                                                       |

#### *Standalone Worker Configuration Options*

This section describes worker parameters that are specific to standalone configurations.

The `offset.storage.file.filename` and `rest.port` parameter are specific to the standalone worker configuration. These parameters are sent in the `connect-standalone.properties` file.

#### Table

| Parameter                           | Description                                                                                                                                                                                                |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rest.port</b>                    | Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this setting must have different values for each instance. Type: int. Default: 8083       |
| <b>offset.storage.file.filename</b> | The file to store connector offsets in. By storing offsets on disk, a standalone process can be stopped and started on a single node and resume where it previously left off. Type: string. Default: empty |

#### *Distributed Worker Configuration Options*

This topic describes the worker parameters that are specific to distributed configurations.

In addition to the common worker configuration options, the following are available in distributed mode. These parameters are set in the `connect-distributed.properties` file.

#### Table

| Parameter                   | Description                                                                                                                                                                                                                                                      | Type   | Default |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|---------|
| <b>group.id</b>             | A unique string that identifies the Connect cluster group that the worker belongs to.                                                                                                                                                                            | string | ""      |
| <b>config.storage.topic</b> | The name of the HPE Ezmeral Data Fabric Event Streams topic to store connector and task configuration data in. This <i>must</i> be the same for all workers with the same <code>group.id</code> .<br><br>For example: <code>/path/to/stream:topic-prefix-</code> | string | ""      |

Table (Continued)

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Type   | Default |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|---------|
| <b>status.storage.topic</b>     | The name of the HPE Ezmeral Data Fabric Event Streams topic where connector and task configuration updates are stored. This <i>must</i> be the same for all workers with the same group.id.                                                                                                                                                                                                                                                                            | string | ""      |
| <b>offset.storage.topic</b>     | The HPE Ezmeral Data Fabric Event Streams topic to store offset data for connectors in. This <i>must</i> be the same for all workers with the same group.id.<br><br>For example: /path/to/stream:topic-prefix-                                                                                                                                                                                                                                                         | string | ""      |
| <b>heartbeat.interval.ms</b>    | The expected time between heartbeats to the group coordinator when using Kafka's group management facilities.<br><br>Heartbeats are used to ensure that the worker's session stays active and to facilitate rebalancing when new members join or leave the group. The value must be set lower than session.timeout.ms, but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances. | int    | 3000    |
| <b>session.timeout.ms</b>       | The timeout used to detect failures when using Kafka's group management facilities.                                                                                                                                                                                                                                                                                                                                                                                    | int    | 30000   |
| <b>connections.max.idle.ms</b>  | Close idle connections after the number of milliseconds specified by this config.                                                                                                                                                                                                                                                                                                                                                                                      | long   | 540000  |
| <b>receive.buffer.bytes</b>     | The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.                                                                                                                                                                                                                                                                                                                                                                                               | int    | 32768   |
| <b>request.timeout.ms</b>       | The configuration controls the maximum amount of time the client will wait for the response of a request.<br><br>If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.                                                                                                                                                                                              | int    | 40000   |
| <b>send.buffer.bytes</b>        | The size of the TCP send buffer (SO_SNDBUF) to use when sending data.                                                                                                                                                                                                                                                                                                                                                                                                  | int    | 131072  |
| <b>worker.sync.timeout.ms</b>   | When the worker is out of sync with other workers and needs to resynchronize configurations, wait up to this amount of time before giving up, leaving the group, and waiting a backoff period before rejoining.                                                                                                                                                                                                                                                        | int    | 3000    |
| <b>worker.unsync.backoff.ms</b> | When the worker is out of sync with other workers and fails to catch up within worker.sync.timeout.ms, leave the Connect cluster for this long before rejoining.                                                                                                                                                                                                                                                                                                       | int    | 300000  |
| <b>client.id</b>                | An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just IP/port by allowing a logical application name to be included in server-side request logging.                                                                                                                                                                                                                                   | string | ""      |
| <b>metadata.max.age.ms</b>      | The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.                                                                                                                                                                                                                                                                          | long   | 300000  |

Table (Continued)

| Parameter                       | Description                                                                                                                                                                                                                      | Type | Default |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| <b>metric.reporters</b>         | A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics. | list | []      |
| <b>metrics.num.samples</b>      | The number of samples maintained to compute metrics.                                                                                                                                                                             | int  | 2       |
| <b>metrics.sample.window.ms</b> | The number of samples maintained to compute metrics.                                                                                                                                                                             | long | 30000   |
| <b>reconnect.backoff.ms</b>     | The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.                 | long | 50      |
| <b>retry.backoff.ms</b>         | The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.                                                              | long | 100     |

*Security Configuration Options*

Describes Kafka Connect security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Kafka Connect REST API clients and the Kafka Connect REST Gateway. By default, Kafka Connect is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka Connect.

Starting in EEP 7.0.0 (Core 6.2.0 and KAKFA Connect 5.2.1.0) impersonation and authentication are disabled, by default, in insecure clusters.

Configure security for Kafka Connect through the security parameters in the `connect-distributed.properties` file.

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**Note:** Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

Table

| Parameter                        | Description                                                                                                                                                                                                                                                                                           | Type    | Default        |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|----------------|
| listeners                        | Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. If a listener uses HTTPS, the appropriate SSL configuration parameters need to be set as well. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8082</code> | list    | none           |
| ssl.cipher.suites                | A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.                                                                                                                                                                                                 | list    | none           |
| authentication.enable            | Enable authentication. MapR supports multiple authentication methods at same time: Basic and MapR SASL.                                                                                                                                                                                               | boolean | false          |
| authentication.cookie.expiration | The option is used to specify expiration time (in seconds) for authentication cookie.                                                                                                                                                                                                                 | long    | 7200 (2 hours) |

Table (Continued)

| Parameter                             | Description                                                                                                                                                                                                                                                                       | Type    | Default                                                                                                                                     |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------|
| impersonation.enable                  | Whether or not to enable impersonation, if disabled - all manipulation will be performed from the admin of cluster user.                                                                                                                                                          | boolean | false                                                                                                                                       |
| headers.file                          | The option is used to specify XML file that contains security and custom headers. The headers will be added to a response by Jetty server.                                                                                                                                        | string  | none                                                                                                                                        |
| hadoop.http.authentication.types      | A list of hadoop authentication types for MultiMechsAuthenticationHandler                                                                                                                                                                                                         | list    | mapauth, basic                                                                                                                              |
| ssl.cipher.suites.exclude             | A list of disabled SSL cipher suites. This is a comma-separated list.                                                                                                                                                                                                             | list    | <ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .*DES.*</li> <li>• .*MD5.*</li> <li>• .*RC4.*</li> </ul> |
| ssl.disabled.protocols                | The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.                                                                                                                                                                                   | list    | <ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>                                                                |
| ssl.enabled.protocols                 | The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.                                                                                                                                             | list    | empty                                                                                                                                       |
| ssl.endpoint.identification.algorithm | The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=http s. Leave blank to use Jetty's default. | string  | none                                                                                                                                        |
| ssl.key.password                      | The password of the private key in the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.                                                                                                                                  | string  | empty                                                                                                                                       |
| ssl.keymanager.algorithm              | The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.                                                                                                                                                                            | string  | none                                                                                                                                        |
| ssl.keystore.location                 | Location of the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.                                                                                                                                                         | string  | empty                                                                                                                                       |
| ssl.keystore.password                 | The store password for the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.                                                                                                                                              | string  | empty                                                                                                                                       |
| ssl.keystore.type                     | The type of keystore file.                                                                                                                                                                                                                                                        | string  | JKS                                                                                                                                         |
| ssl.protocol                          | The SSL protocol used to generate the SslContextFactory.                                                                                                                                                                                                                          | string  | TLSv1.2                                                                                                                                     |
| ssl.provider                          | The SSL security provider name. Leave blank to use Jetty's default.                                                                                                                                                                                                               | string  | none                                                                                                                                        |

Table (Continued)

| Parameter                  | Description                                                                                              | Type   | Default |
|----------------------------|----------------------------------------------------------------------------------------------------------|--------|---------|
| ssl.trustmanager.algorithm | The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default. | string | none    |
| ssl.truststore.location    | Location of the trust store. Required only to authenticate HTTPS clients.                                | string | empty   |
| ssl.truststore.password    | The store password for the trust store file.                                                             | string | empty   |
| ssl.truststore.type        | The type of trust store file.                                                                            | string | JKS     |

### SSL Security Configuration

Describes how to configure Kafka Connect security on a HPE Ezmeral Data Fabric cluster.

### Secure by Default

As of Core 6.0, the Installer performs the Kafka Connect configuration for new installations. This means that:

- If core is installed as *secure*, then Kafka Connect is also installed as *secure*.
- If core is installed as *unsecure*, then Kafka Connect is also installed as *unsecure*.

### Manually Securing Kafka Connect Only

 **CAUTION:** This configuration is *not* a typical configuration.

If you have an *unsecure* HPE Ezmeral Data Fabric cluster, and you want to *secure* Kafka Connect, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `connect-distributed.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8083
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka Connect.

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8083/connectors --cacert <certificate-path>
```

### Manually Unsecuring Kafka Connect

 **Warning:** This scenario is *NOT* recommended or supported.

If you have a *secure* HPE Ezmeral Data Fabric cluster, and you want to *unsecure* Kafka Connect, do the following:

1. In the `connect-distributed.properties` configuration file, change `https://` to `http://` for the listeners and remove the `ssl.*` properties. For example:

```
listeners=http://0.0.0.0:8083
```

2. Restart Kafka Connect.

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

### *User Impersonation*

Describes how to disable, enable, and use impersonation with Kafka Connect.

User impersonation enables Kafka Connect jobs to be submitted as a particular user. Without impersonation, Kafka Connect submits jobs as the user that started the worker

On a HPE Ezmeral Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation and PAM authentication in Kafka Connect are enabled on all types of security.

### **Disabling User Impersonation**

To disable user impersonation, disable the PAM authentication and impersonation properties in the `opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties` file.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable impersonation, set `impersonation.enable=false`.

### **JDBC Connector**

The topics describes the JDBC connector, drivers, and configuration parameters.

The JDBC connector allows you to import data from any relational database into HPE Ezmeral Data Fabric Event Streams and export data from HPE Ezmeral Data Fabric Event Streams to any relational database with a JDBC driver. By using JDBC, this connector can support a wide variety of databases without requiring custom code for each one.

The JDBC connector provides flexibility regarding which databases you can import data from and how that data is imported. JDBC connector implements the data copying functionality on the generic JDBC APIs, and relies on JDBC drivers to handle the database-specific implementation of those APIs.

The supported relational databases include:

- MySQL
- Oracle
- PostgreSQL
- SQLite
- SQL Server
- Hive is supported for the JDBC Source Connector

### *JDBC Driver*

Kafka Connect for HPE Ezmeral Data Fabric Event Streams provides a JDBC driver jar along with the connector configuration.

The JDBC driver (kafka-connect-jdbc) is set up by specifying the CLASSPATH variable. See [Installing HPE Ezmeral Data Fabric Event Streams Tools](#) on page 194.

The packaged connector is installed in the **share/java/kafka-connect-jdbc** directory, relative to the installation directory.

Alternatively, to add a new driver to the CLASSPATH,

1. Put the classpath of the connectors in the **kafka-connect-jdbc** directory:

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<connector version>/
share/java/kafka-connect-jdbc/
```

2. Create a symlink into the **share/java/kafka-connect-jdbc/** directory.

#### JDBC Configuration Options

Use the following parameters to configure the Kafka Connect for HPE Ezmeral Data Fabric Event Streams JDBC connector; they are modified in the `quickstart-sqlite.properties` file.

#### Configuration Modes

In *standalone* mode, JDBC connector configuration is specified in the **quickstart-sqlite.properties** file. Additional configurations such as the offset storage location and the port for the REST interface are specified in the **connect-standalone.properties** file. See [Configuring in Standalone Mode](#) on page 4120.

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 4148 and [PUT /connectors/\(string:name\)/config](#) on page 4150 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See [Configuring in Distributed Mode](#) on page 4121 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

#### JDBC Source Configuration Options

Table

| Parameters             | Description                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>connection.url</b>  | JDBC connection URL for the database to load. <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul> |
| <b>connection.user</b> | JDBC connection user. <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: NULL</li> </ul>                       |

Table (Continued)

| Parameters                       | Description                                                                                                                                                                                                                                                           |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>connection.password</b>       | JDBC connection password. <ul style="list-style-type: none"> <li>Type: password</li> <li>Default: NULL</li> </ul>                                                                                                                                                     |
| <b>connection.attempts</b>       | Maximum number of attempts to retrieve a valid JDBC connection. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 3</li> </ul>                                                                                                                       |
| <b>connection.backoff.ms</b>     | Backoff time in milliseconds between connection attempts. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 10000</li> </ul>                                                                                                                        |
| <b>table.whitelist</b>           | List of tables to include in copying. If specified, table.blacklist may not be set. <ul style="list-style-type: none"> <li>Type: list</li> <li>Default: []</li> </ul>                                                                                                 |
| <b>table.blacklist</b>           | List of tables to exclude from copying. If specified, table.whitelist may not be set. <ul style="list-style-type: none"> <li>Type: list</li> <li>Default: []</li> </ul>                                                                                               |
| <b>numeric.precision.mapping</b> | Whether or not to attempt mapping <i>numeric</i> values by precision to integral types. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>                                                                                       |
| <b>schema.pattern</b>            | Schema pattern to fetch table metadata from the database. <p>" " - Retrieves those without a schema.</p> <p>* - NULL (default) means that the schema name should not be used to narrow the search, all tables metadata would be fetched, regardless their schema.</p> |

| Parameters                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b>                  | <p>The mode for updating a table each time it is polled. Options include:</p> <ul style="list-style-type: none"> <li>• bulk - perform a bulk load of the entire table each time it is polled.</li> <li>• incrementing - use a strictly incrementing column on each table to detect only new rows. Note that this will not detect modifications or deletions of existing rows.</li> <li>• timestamp - use a timestamp (or timestamp-like) column to detect new and modified rows. This assumes the column is updated with each write, and that values are monotonically incrementing, but not necessarily unique.</li> <li>• timestamp+incrementing - use two columns, a timestamp column that detects new and modified rows and a strictly incrementing column which provides a globally unique ID for updates so each row can be assigned a unique stream offset.</li> </ul> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul> <p>Valid Values: [, bulk, timestamp, incrementing, timestamp+incrementing]</p> <p>The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an autoincrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul> <p> <b>Note:</b> If you are using Hive JDBC with incrementing or timestamp mode, you should set the <code>validate.non.null</code> property to false because there are no "not null" columns in Hive.</p> |
| <b>timestamp.column.name</b> | <p>The name of the timestamp column to use to detect new or modified rows. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>validate.non.null</b>     | <p>By default, the JDBC connector will validate that all incrementing and timestamp tables have NOT NULL set for the columns being used as their ID/timestamp. If the tables don't, JDBC connector will fail to start. Setting this to false will disable these checks.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: true</li> </ul> <p> <b>Note:</b> If this parameter is false, specify exactly all columns that need to be imported to HPE Ezmeral Data Fabric Event Streams in the query parameter. For example instead of "query" : "select * from table", use "query" : "select col1, col2 from table"</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Table (Continued)

| Parameters                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>incrementing.column.name</b> | <p>The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an auto-incrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                               |
| <b>query</b>                    | <p>If specified, the query to perform to select new or updated rows. Use this setting to join tables, select subsets of columns in a table, or filter data. If used, this connector will only copy data using this query – whole-table copying will be disabled. Different query modes may still be used for incremental updates, but in order to properly construct the incremental query, it must be possible to append a WHERE clause to this query (i.e. no WHERE clauses may be used). If you use a WHERE clause, it must handle incremental queries itself.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul> |
| <b>poll.interval.ms</b>         | <p>Frequency (milliseconds) to poll for new data in each table.</p> <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 5000</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>batch.max.rows</b>           | <p>Maximum number of rows to include in a single batch when polling for new data. This setting can be used to limit the amount of data buffered internally in the connector.</p> <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 100</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>table.poll.interval.ms</b>   | <p>Frequency (milliseconds) to poll for new or removed tables, which may result in updated task configurations to start polling for data in added tables or stop polling for data in removed tables.</p> <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 60000</li> </ul>                                                                                                                                                                                                                                                                                                                                                             |
| <b>topic.prefix</b>             | <p>Prefix to prepend to table names to generate the name of the Kafka topic to publish data to, or in the case of a custom query, the full name of the topic to publish to. For example: <code>/path/to/stream:topic-prefix-</code>.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                              |

| Parameters               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>insert.mode</b>       | <p>The insertion mode to use.</p> <ul style="list-style-type: none"> <li>• INSERT - Use standard SQL INSERT statements.</li> <li>• UPSERT - Use the appropriate upsert semantics for the target database if it is supported by the connector. For example: INSERT or IGNORE</li> <li>• UPDATE - Use the appropriate update semantics for the target database if it is supported by the connector. For example: UPDATE</li> <li>• Type: string</li> <li>• Default: INSERT</li> <li>• Valid Values: insert, upsert, update</li> </ul>                                       |
| <b>batch.size</b>        | <p>Specifies how many records to attempt to batch together for insertion into the destination table, when possible.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 3000</li> <li>• Valid Values: 0,...</li> </ul>                                                                                                                                                                                                                                                                                                                             |
| <b>table.name.format</b> | <p>A format string for the destination table name, which may contain <code>\${topic}</code> as a placeholder for the originating topic name. For example, <code>table_\${topic}</code> for the topic <code>orders</code> maps to the table name <code>table_orders</code>.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: <code>\${topic}</code></li> </ul>                                                                                                                                                                                |
| <b>pk.mode</b>           | <p>The primary key mode, also refer to <code>pk.fields</code> documentation for interplay. Supported modes are:</p> <ul style="list-style-type: none"> <li>• none - No keys utilized.</li> <li>• kafka - Kafka coordinates are used as the PK.</li> <li>• record_key - Field(s) from the record key are used, which may be a primitive or a struct.</li> <li>• record_value - Field(s) from the record value are used, which must be a struct.</li> <li>• Type: string</li> <li>• Default: none</li> <li>• Valid Values: none, kafka, record_key, record_value</li> </ul> |

Table (Continued)

| Parameters              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pk.fields</b>        | <p>List of comma-separated primary key field names. The runtime interpretation of this config depends on the pk.mode:</p> <ul style="list-style-type: none"> <li>• none - Ignored as no fields are used as primary key in this mode.</li> <li>• kafka - Must be a trio representing the Kafka coordinates. Defaults to __connect_topic,__connect_partition,__connect_offset if empty.</li> <li>• record_key - If empty, all fields from the key struct will be used, otherwise used to extract the desired fields - for primitive key only a single field name must be configured.</li> <li>• record_value - If empty, all fields from the value struct will be used, otherwise used to extract the desired fields.</li> <li>• Type: list</li> <li>• Default: ""</li> </ul> |
| <b>fields.whitelist</b> | <p>List of comma-separated record value field names. If empty, all fields from the record value are utilized, otherwise used to filter to the desired fields. Note: pk.fields is applied independently in the context of which field(s) form the primary key columns in the destination database, while this configuration is applicable for the other columns.</p> <ul style="list-style-type: none"> <li>• Type: list</li> <li>• Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                   |
| <b>auto.create</b>      | <p>Whether to automatically create the destination table based on record schema if it is found to be missing by issuing CREATE.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: false</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>auto.evolve</b>      | <p>Whether to automatically add columns in the table schema when found to be missing relative to the record schema by issuing ALTER.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: false</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>max.retries</b>      | <p>The maximum number of times to retry on errors before failing the task.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 10</li> <li>• Valid Values: 0,..</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>retry.backoff.ms</b> | <p>The time in milliseconds to wait following an error before a retry attempt is made.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 3000</li> <li>• Valid Values: 0,..</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### Whitelists and Custom Query JDBC Examples

This section provides common usage scenarios using whitelists and custom queries.

#### Using Whitelists

Use a whitelist to limit changes to a subset of tables in a MySQL database, using id and modifiedcolumns that are standard on all whitelisted tables to detect rows that have been modified. This mode is the most robust because it can combine the unique, immutable row IDs with modification timestamps to guarantee modifications are not missed even if the process dies in the middle of an incremental update query.

The following is an example of a whitelist.

**Note:** Before running this example, you need to create the stream `/kafka-connect`

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector tasks.max=10
connection.url=jdbc:mysql://mysql.example.com:3306/my_database?
user=alice&password=secret
table.whitelist=users,products,transactions
mode=timestamp+incrementing
timestamp.column.name=modified
incrementing.column.name=id
topic.prefix=/kafka-connect:mysql-

```

#### Using Custom Queries

Use a custom query instead of loading tables to join data from multiple tables. As long as the query does not include its own filtering, you can still use the built-in modes for incremental queries (in this case, using a timestamp column).

**Note:** This limits you to a single output per connector and because there is no table name, the topic “prefix” is actually the full topic name in this case.

The following is an example of a custom query.

**Note:** Before running this example, you need to create the stream `/kafka-connect`

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector
tasks.max=10
connection.url=jdbc:postgresql://postgres.example.com/test_db?
user=bob&password=secret&ssl=true
query=SELECT users.id,
users.name,
transactions.timestamp,
transactions.user_id,
transactions.payment FROM users JOIN transactions ON (users.id =
transactions.user_id)
mode=timestamp
timestamp.column.name=timestamp
topic.prefix=/kafka-connect:mysql-joined-data

```

### Streaming Data JDBC Examples

This section provides common usage scenarios of streaming data between different databases to or from HPE Ezmeral Data Fabric Event Streams.

## Streaming Data from HPE Ezmeral Data Fabric Event Streams to a MySQL Database

The following is example code for streaming data from HPE Ezmeral Data Fabric Event Streams stream topics to a MySQL database.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-sink-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSinkConnector",
"connection.url": "jdbc:mysql://hostname:3306/mysql_db?
user=<user>&password=<password>",
"auto.create": "true",
"topics": "/kafka-connect:topic1",
"tasks.max": "2",
"insert.mode": "insert"
}}
```

## Streaming Data from a MySQL Database to HPE Ezmeral Data Fabric Event Streams

The following is example code for streaming data from a MySQL database to HPE Ezmeral Data Fabric Event Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-source-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url": "jdbc:mysql://hostname:3306/newdb?
user=<user>&password=<password>"
"mode": "incrementing",
"incrementing.column.name": "id",
"topic.prefix": "/kafka-connect:mysql-",
"tasks.max": "1"
}}
```

## Streaming Data from a Hive Database to HPE Ezmeral Data Fabric Event Streams

The following is example code for streaming data from a Hive database to HPE Ezmeral Data Fabric Event Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "hive-source-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url": "jdbc:hive2://hostname:10000/
database_name;user=<user>;password=<pa
ssword>",
"mode": "bulk",
"topic.prefix": "/kafka-connect:hive-",
"tasks.max": "1"
}}
```

 **Note:** For a secure HPE Ezmeral Data Fabric cluster, use next connection.url jdbc:hive2://hostname:10000/database\_name;auth=maprsasl

### Managing Kafka Connect Services

Lists the commands you use to start, stop, or restart Kafka Connect Services

Use the `maprcli node services` command with the `-action` parameter as follows:

```
maprcli node services -name kafka-connect -action start -nodes <node_list>
```

```
maprcli node services -name kafka-connect -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-connect -action restart -nodes
<node_list>
```

For more information see [node services](#) on page 1939

### HDFS Connector

These topics describe the Kafka Connect for HPE Ezmeral Data Fabric Event Streams HDFS connector, driver, and configuration parameters.

The HDFS connector allows you to export data from HPE Ezmeral Data Fabric Event Streams topics to filesystem or HDFS files in a variety of formats. In addition, Hive integration is available, which can be use to make data immediately available for querying with HiveQL.

#### *HDFS Configuration Options*

Use the following parameters to configure the Kafka Connect for HPE Ezmeral Data Fabric Event Streams HDFS connector.

 **Note:** For the HDFS connector, both Avro and Parquet files can be written.

In *standalone* mode, specify the HDFS connector configuration in the **quickstart-hdfs.properties** file. You can also configure the offset storage location and the port for the REST interface, which are specified in the **connect-standalone.properties** file. See [Configuring in Standalone Mode](#) on page 4120.

```
/opt/mapr/kafka-connect-hdfs/kafka-connect-hdfs-<version>/etc/
kafka-connect-hdfs/quickstart-hdfs.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 4148 and [PUT /connectors/\(string:name\)/config](#) on page 4150 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See [Configuring in Distributed Mode](#) on page 4121 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**Table**

| Parameter         | Description                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>flush.size</b> | Number of records written to the filesystem before invoking file commits. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: ""</li> </ul> |

Table (Continued)

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>hdfs.url</i></b>                     | The filesystem connection URL. This configuration has the format of maprfs://hostname:port and specifies the MapR filesystem to export data to. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                        |
| <b><i>connect.hdfs.keytab</i></b>          | The path to the keytab file for the HDFS connector principal. This keytab file should only be readable by the connector user. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                          |
| <b><i>connect.hdfs.principal</i></b>       | The principal used when the filesystem is using Kerberos for authentication. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                           |
| <b><i>format.class</i></b>                 | The format class used when writing data to the filesystem. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.avro.AvroFormat"</li> </ul> <p> <b>Note:</b> If you want to write to a Parquet set, use "io.confluent.connect.hdfs.parquet.ParquetFormat"</p> |
| <b><i>hadoop.conf.dir</i></b>              | The Hadoop configuration directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                    |
| <b><i>hadoop.home</i></b>                  | The Hadoop home directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                             |
| <b><i>hdfs.authentication.kerberos</i></b> | Specifies whether the filesystem uses Kerberos for authentication. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>                                                                                                                                                                                                                                 |
| <b><i>hdfs.namenode.principal</i></b>      | The Kerberos principal for CLDB. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                       |
| <b><i>hive.conf.dir</i></b>                | The Hive configuration directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                      |

Table (Continued)

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>hive.database</i></b>        | The database used when the connector creates tables in Hive. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "default"</li> </ul>                                                                                                                                                                                                                                                                                                                                                                            |
| <b><i>hive.home</i></b>            | The Hive home directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b><i>hive.integration</i></b>     | Specifies whether Hive is integrated when running the connector. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>                                                                                                                                                                                                                                                                                                                                                                           |
| <b><i>hive.metastore.uris</i></b>  | The Hive metastore URIs. Can be an IP address or fully-qualified domain name and port of the metastore host. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                   |
| <b><i>logs.dir</i></b>             | Top-level filesystem directory to store the write ahead logs. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "logs"</li> </ul>                                                                                                                                                                                                                                                                                                                                                                              |
| <b><i>partitioner.class</i></b>    | The partitioner used when writing data to the filesystem. You can use DefaultPartitioner, which preserves the Kafka partitions; FieldPartitioner, which partitions the data to different directories according to the value of the partitioning field specified in partition.field.name; TimeBasedPartitioner, which partitions data according to the time ingested to the filesystem. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.partitioner.DefaultPartitioner"</li> </ul> |
| <b><i>rotate.interval.ms</i></b>   | The time interval (milliseconds) before invoking file commits. This configuration ensures that file commits are invoked every configured interval. This configuration is useful when data ingestion rate is low and the connector didn't write enough messages to commit files. The default value -1 means that this feature is disabled. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: -1</li> </ul>                                                                                                        |
| <b><i>schema.compatibility</i></b> | The schema compatibility rule used when the connector is observing schema changes. The supported configurations are NONE, BACKWARD, FORWARD and FULL. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "NONE"</li> </ul>                                                                                                                                                                                                                                                                                      |

Table (Continued)

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>topics</b>                | A list of topics to use as input for the HDFS connector. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                                  |
| <b>topics.dir</b>            | Top-level filesystem directory to store the data ingested from Kafka. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "topics"</li> </ul>                                                                                                                                                                                                                                                                                                                               |
| <b>locale</b>                | The locale used when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                              |
| <b>partition.duration.ms</b> | The duration of a partition (milliseconds) used by TimeBasedPartitioner. The default value -1 means that TimeBasedPartitioner is not being used. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: -1</li> </ul>                                                                                                                                                                                                                                                            |
| <b>partition.field.name</b>  | The name of the partitioning field when FieldPartitioner is used. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                         |
| <b>path.format</b>           | This configuration is used to set the format of the data directories when partitioning with TimeBasedPartitioner. The format set in this configuration converts the Unix timestamp to proper directories strings. For example, if you set <code>path.format='year'=YYYY/'month'=MM/'day'=dd/'hour'=HH/</code> , the data directories will have the format <code>/year=2015/month=12/day=07/hour=15</code> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul> |
| <b>shutdown.timeout.ms</b>   | Clean shutdown timeout. This makes sure that asynchronous Hive metastore updates are completed during connector shutdown. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 3000</li> </ul>                                                                                                                                                                                                                                                                                 |
| <b>timezone</b>              | The timezone to use when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>                                                                                                                                                                                                                                                                                                                                          |

Table (Continued)

| Parameter                                     | Description                                                                                                                                                                                                                                                              |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>filename.offset.zero.pad.width</i></b>  | Sets the width to the zero-pad offsets in the filesystem filenames. If the offsets are too short it provides fixed width filenames that can be ordered by simple lexicographic sorting. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 10</li> </ul> |
| <b><i>kerberos.ticket.renew.period.ms</i></b> | The period in milliseconds to renew the Kerberos ticket. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 3600000 (milliseconds)</li> </ul>                                                                                                           |
| <b><i>retry.backoff.ms</i></b>                | Used to notify Kafka Connect to retry delivering a message batch or performing recovery in case of transient exceptions. The retry backoff is in milliseconds. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000 (milliseconds)</li> </ul>        |
| <b><i>schema.cache.size</i></b>               | The sized of the schema cache used in the Avro converter. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 1000</li> </ul>                                                                                                                             |
| <b><i>storage.class</i></b>                   | The underlying storage layer. The default is MapR-FS. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.storage.HdfsStorage"</li> </ul>                                                                                   |

### *HDFS Examples*

These examples provides sample code for streaming data to and from filesystem.

### **Streaming Data from HPE Ezmeral Data Fabric Event Streams to filesystem**

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Event Streams to filesystem.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
 "name": "maprfs-sink-connector",
 "config": {
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "1",
 "topics": "/kafka-connect:topic1",
 "hdfs.url": "maprfs://",
 "flush.size": "5",
 "rotate.interval.ms": "1000"
 }
}
```

## Streaming Data from HPE Ezmeral Data Fabric Event Streams to filesystem in Parquet

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Event Streams to filesystem in Parquet.

```
POST /connectors HTTP/1.1
 Host: connect.example.com
 Content-Type: application/json
 Accept: application/json

 {
 "name": "hdfs-connector-parquet",
 "config": {

```

### Hive Integration

This topic describes how to integrate a Hive database with Kafka Connect for HPE Ezmeral Data Fabric Event Streams.

Kafka Connect for HPE Ezmeral Data Fabric Event Streams supports Hive integration. If a Hive database is enabled, an external Hive table is created and that can be queried via Hive shell.

**Note:** As of Kafka Connect 4.0.0 for HPE Ezmeral Data Fabric Event Streams Hive 2.1 is supported.

The Hive table name is constructed using a topic name in the following manner:

- In the HPE Ezmeral Data Fabric Event Streams topic, /stream\_path:topic-name, the first forward slash (/) is removed, all other slashes are translated to underscores ( \_ ), and the colon (:) is translated to an underscore ( \_ ).
- All non-alphanumeric and non-underscore characters are removed from the string representing the Hive table name.

### Renaming Topics for Hive usage

The following example shows a topic named /test-12:test1 is renamed for Hive usage.

```
$ hadoop fs -ls -R /topics
drwxr-xr-x - mapr mapr 1 2016-10-05 19:46 /topics/+tmp
drwxr-xr-x - mapr mapr 1 2016-10-05 19:46 /topics/+tmp/
test12_test1
drwxr-xr-x - mapr mapr 0 2016-10-05 19:50 /topics/+tmp/
test12_test1/partition=1
drwxr-xr-x - mapr mapr 1 2016-10-05 19:46 /topics/
test12_test1
drwxr-xr-x - mapr mapr 2 2016-10-05 19:50 /topics/
test12_test1/partition=1
-rwxr-xr-x 3 mapr mapr 241 2016-10-05 19:47 /topics/
test12_test1/partition=1/test12_test1+1+0000000078+0000000080.avro
-rwxr-xr-x 3 mapr mapr 241 2016-10-05 19:50 /topics/
test12_test1/partition=1/test12_test1+1+0000000081+0000000083.avro
```

The following query and results shows the topic data in the Hive table.

```
> select * from test12_test1;
 OK
16/10/05 20:06:59 INFO mapred.FileInputFormat: Total input paths to
process : 2

```

### Streaming Data from HPE Ezmeral Data Fabric Event Streams to the Hive database

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Event Streams to the Hive database.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
 "name": "hdfs-connector-hive",
 "config": {
 "hive.integration": "true",
 "hive.database": "db3",
 "hive.conf.dir": "/opt/mapr/hive/hive-1.2/conf",
 "hive.metastore.uris": "thrift://localhost:9083",
 "schema.compatibility": "BACKWARD",
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "1",
 "topics": "/kafka-connect:topic3",
 "hdfs.url": "maprfs:///",
 "flush.size": "1"
 }
}
```

### REST API

The Kafka Connect REST API for HPE Ezmeral Data Fabric Event Streams manages connectors.

In standalone mode, a connector request is submitted on the command line. This mode is useful for getting status information, adding and removing connectors without stopping the process, and testing and debugging.

In distributed mode, the REST API is the primary interface to the cluster. Requests can be made to any cluster member where the REST API automatically forwards requests.

### Content Types

The REST API supports application/json as both the request and response entity content type. For example:

```
Accept: application/json
Content-Type: application/json
```

### Status & Errors

The REST API returns standards-compliant HTTP statuses.

**Note:** By default, the Kafka Connect REST API for HPE Ezmeral Data Fabric Event Streams service in run on port 8083.

Table

| HTTP   | URI                                                           | Description                                                                                                                                                                                 |
|--------|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GET    | /connectors                                                   | Gets a list of active connectors.                                                                                                                                                           |
| POST   | /connectors                                                   | Creates a new connector, returning the current connector information is successful.                                                                                                         |
| GET    | /connectors/{string:name}                                     | Gets information about the connector.                                                                                                                                                       |
| GET    | /connectors/{string:name}/config                              | Gets the configuration for the connector.                                                                                                                                                   |
| PUT    | /connectors/{string:name}/config                              | Creates a new connector using the given configuration or updates the configuration for an existing connector.                                                                               |
| GET    | /connectors/{string:name}/tasks                               | Gets a list of tasks current running for the connector.                                                                                                                                     |
| DELETE | /connectors/{string:name}/                                    | Deletes a connector, halting all tasks and deleting its configuration.                                                                                                                      |
| GET    | /connector-plugins                                            | Lists the connector plugins available on this worker,                                                                                                                                       |
| POST   | /connectors/{string:name}/restart                             | Restarts a connector and its tasks.                                                                                                                                                         |
| GET    | /connectors/{string:name}/tasks/{int:taskId}/status           | Gets the status for a task.                                                                                                                                                                 |
| POST   | /connectors/{string:name}/tasks/{int:number of tasks}/restart | Restarts an individual task.                                                                                                                                                                |
| PUT    | /connectors/{string:name}/pause                               | Pauses the connector and its tasks, which stops message processing until the connector is resumed.                                                                                          |
| PUT    | /connectors/{string:name}/resume                              | Resumes a paused connector or do nothing if the connector is not paused.                                                                                                                    |
| GET    | /connectors/{string:name}/status                              | Get current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks. |

*GET /connectors*

Gets a list of active connectors.

### Syntax

```
http://<host>:8083/connectors
```

### Request Example

```
GET /connectors HTTP/1.1 Host: connect.example.com Accept: application/json
```

### Response Example

The response JSON object is in the following form:

- **connectors** (*array*) – List of connector names.

```
HTTP/1.1 200 OK Content-Type: application/json ["my-jdbc-source", "my-hdfs-sink"]
```

*POST /connectors*

Creates a new connector, returning the current connector information if successful.

**Description**

The POST request along with the parameters is used to create connectors in distributed mode.

The following table provides the parameters needed to create a new connector.

**Table**

| Parameters                                  | Description                                                                                                                                                            |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>name</b> ( <i>string</i> )               | Name of the created connector                                                                                                                                          |
| <b>config</b> ( <i>map</i> )                | Configuration parameters for the connector. See <a href="#">HDFS Connector</a> on page 4140 and <a href="#">JDBC Connector</a> on page 4130 for configuration options. |
| <b>tasks</b> ( <i>array</i> )               | List of active tasks generated by the connector.                                                                                                                       |
| <b>tasks[i].connector</b> ( <i>string</i> ) | Name of the connector that the task belongs to.                                                                                                                        |
| <b>tasks[i].task</b> ( <i>int</i> )         | Task ID within the connector.                                                                                                                                          |

**Syntax**

```
http://<host>:8083/connectors/?
name=<connector_name>&config=<config_parameters>
```

**Request Example**

```
POST /connectors HTTP/1.1 Host: connect.example.com Content-Type:
application/json Accept: application/json
{
 "name": "hdfs-sink-connector",
 "config": {
 "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "1",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 }
}
```

**Response Example**

The response JSON object is in the following form:

- **name** (*string*) – Name of the connector to create.
- **config** (*map*) – Configuration parameters for the connector. All values should be strings.
- **tasks** (*array*) – List of active tasks generated by the connector.

```
HTTP/1.1 201 Created Content-Type: application/json
{
 "name": "hdfs-sink-connector",
 "config":
```

```

 {
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 },
 "tasks": [
 { "connector": "hdfs-sink-connector", "task": 1 },
 { "connector": "hdfs-sink-connector", "task": 2 },
 { "connector": "hdfs-sink-connector", "task": 3 }
]
 }
}

```

*GET /connector/(string:name)*

Gets information about a specific connector.

### Description

#### Table

| Parameters                                  | Description                                      |
|---------------------------------------------|--------------------------------------------------|
| <b>name</b> ( <i>string</i> )               | Name of the created connector.                   |
| <b>config</b> ( <i>map</i> )                | Configuration parameters for the connector.      |
| <b>tasks</b> ( <i>array</i> )               | List of active tasks generated by the connector. |
| <b>tasks[i].connector</b> ( <i>string</i> ) | Name of the connector the task belongs to.       |
| <b>tasks[i].task</b> ( <i>int</i> )         | Task ID within the connector.                    |

### Syntax

```
http://<host>:8083/connectors/<name>
```

### Request Example

```
GET /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
Accept: application/json
```

### Response Example

```

HTTP/1.1 200 OK Content-Type: application/json
{
 "name": "hdfs-sink-connector",
 "config": {
 "connector.class":
 "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 },
 "tasks": [
 { "connector": "hdfs-sink-connector", "task": 1 },

```

```
{
 "connector": "hdfs-sink-connector", "task": 2 },
 "connector": "hdfs-sink-connector", "task": 3 }
]
```

*GET /connectors/(string:name)/config*

Gets the configuration for the connector.

### Description

#### Table

| Parameters                   | Description                                 |
|------------------------------|---------------------------------------------|
| <b>config</b> ( <i>map</i> ) | Configuration parameters for the connector. |

### Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

### Request Example

```
GET /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
```

### Response Example

```
HTTP/1.1 200 OK Content-Type: application/json
{
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
}
```

*PUT /connectors/(string:name)/config*

Creates a new connector using the given configuration or updates the configuration for an existing connector. Returns information about the connector after the change has been made.

### Description

The PUT request along with the parameters is used to create connectors in distributed mode.

#### Table

| Parameters                                  | Description                                                                                                                                                            |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>name</b> ( <i>string</i> )               | Name of the created connector.                                                                                                                                         |
| <b>config</b> ( <i>map</i> )                | Configuration parameters for the connector. See <a href="#">HDFS Connector</a> on page 4140 and <a href="#">JDBC Connector</a> on page 4130 for configuration options. |
| <b>tasks</b> ( <i>array</i> )               | List of active tasks generated by the connector.                                                                                                                       |
| <b>tasks[i].connector</b> ( <i>string</i> ) | Name of the connector that the task belongs to.                                                                                                                        |
| <b>tasks[i].task</b> ( <i>int</i> )         | Task ID within the connector.                                                                                                                                          |

## Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

## Request Example

```
PUT /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
{
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
}
```

## Response Example

The response JSON object is in the following form:

- config (map) – Configuration parameters for the connector. All values should be strings.

**Note:** In this example, the return status indicates that the connector was created. In the case of a configuration update, the status would be 200 OK.

```
HTTP/1.1 201 Created Content-Type: application/json

```

*GET /connectors/(string:name)/tasks*

Gets a list of tasks currently running for the connector.

## Description

### Table

| Parameters                           | Description                                                  |
|--------------------------------------|--------------------------------------------------------------|
| <b>tasks</b> ( <i>array</i> )        | List of active task configurations created by the connector. |
| <b>tasks[i].id</b> ( <i>string</i> ) | ID of the task.                                              |

Table (Continued)

| Parameters                                           | Description                                     |
|------------------------------------------------------|-------------------------------------------------|
| <code>tasks[i].id.connector</code> ( <i>string</i> ) | Name of the connector that the task belongs to. |
| <code>tasks[i].id.task</code> ( <i>int</i> )         | Task ID within the connector.                   |
| <code>tasks[i].config</code> ( <i>map</i> )          | Configuration parameters for the task.          |

**Syntax**

```
http://<host>:8083/connectors/<connector_name>/tasks
```

**Request Example**

```
GET /connectors/hdfs-sink-connector/tasks HTTP/1.1 Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK
[
 {
 "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 },
 {
 "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 }
]
```

**DELETE /connectors/(string:name)/**

Deletes a connector by halting all tasks and deleting its configuration.

**Syntax**

```
http://<host>:8083/connectors/<connector_name>/
```

**Request Example**

```
DELETE /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 204 No Content
```

**GET /connector-plugins**

Lists the connector plugins available on this worker.

## Syntax

```
http://<host>:8083/connector-plugins>
```

## Request Example

```
GET /connector-plugins/ HTTP/1.1
Host: connect.example.com
```

## Response Example

```
HTTP/1.1 200 OK

[
 {
 "class": "io.confluent.connect.hdfs.HdfsSinkConnector"
 },
 {
 "class": "io.confluent.connect.jdbc.JdbcSourceConnector"
 }
]
```

## *POST /connectors/(string:name)/restart*

Restarts a connector and its tasks.

## Syntax

```
http://<host>:8083/connectors/<string_name>/restart
```

## Request Example

```
POST /connectors/hdfs-sink-connector/restart HTTP/1.1
Host: connect.example.com
```

## Response Example

Return 409 (Conflict) if rebalance is in process.

```
HTTP/1.1 200 OK
```

## *GET /connectors/(string:name)/tasks/(int:taskId)/status*

Gets the status for a task.

## Syntax

```
http://<host>:8083/connectors/<string_name>/tasks/<task ID>/status
```

## Request Example

```
GET /connectors/hdfs-sink-connector/tasks/1/status HTTP/1.1
Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK
{"state": "RUNNING", "id": 1, "worker_id": "192.168.86.101:8083"}
```

*POST /connectors/(string:name)/tasks/(int:number of tasks)/restart*  
Restarts an individual task.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/tasks/<number of tasks>/restart
```

**Request Example**

```
GET /connectors/hdfs-sink-connector/tasks/1/restart HTTP/1.1
Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK
```

*PUT /connectors/(string:name)/pause*  
Pauses the connector and its tasks, which stops message processing until the connector is resumed.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/pause
```

**Note:** This call is asynchronous and the tasks will not transition to PAUSED state at the same time.

**Request Example**

```
PUT /connectors/hdfs-sink-connector/pause HTTP/1.1
Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 202 Accepted
```

*PUT /connectors/(string:name)/resume*  
Resumes a paused connector or do nothing if the connector is not paused.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/resume
```

**Note:** This call is asynchronous and the tasks will not transition to RUNNING state at the same time.

## Request Example

```
PUT /connectors/hdfs-sink-connector/resume HTTP/1.1
Host: connect.example.com
```

## Response Example

```
HTTP/1.1 202 Accepted
```

### *GET /connectors/(string:name)/status*

Gets current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

## Syntax

```
http://<host>:8083/connectors/<string_name>/status
```

## Request Example

```
GET /connectors/hdfs-sink-connector/status HTTP/1.1
Host: connect.example.com
```

## Response Example

The response JSON object includes the following:

- name (string) – Name of the connector
- connector (map) – Map containing connector status
- tasks[i] (map) – Map containing the task status

```
HTTP/1.1 200 OK

{
 "name": "hdfs-sink-connector",
 "connector": {
 "state": "RUNNING",
 "worker_id": "localhost:8083"
 },
 "tasks":
 [
 {
 "id": 0,
 "state": "RUNNING",
 "worker_id": "localhost:8083"
 },
 {
 "id": 1,
 "state": "FAILED",
 "worker_id": "localhost:8083",
 "trace":
 "org.apache.kafka.common.errors.RecordTooLargeException\n"
 }
]
}
```

### Saving Kafka Connect Configurations

Describes how Kafka Connect configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka Connect is stored in a folder with a timestamp.

- Files are saved *and* overwritten by new configuration files:
  - when upgrading from 4.1.0 to 5.1.2.
  - when upgrading from 5.1.2 to 10.0.0.
- Files are saved only (*not* overwritten):
  - when upgrading from 5.1.2 to 5.1.2.

### Example

The following example shows the list of configuration files that are saved when upgrading from `mapr-kafka-connect 5.1.2 (EEP 7.0.0)` to `mapr-kafka-connect 5.1.2 (EEP 7.0.1)`:

```
ls /opt/mapr/kafka/
kafka-2.1.1 kafka-2.1.1.0.202009090438 kafkaversion

ls /opt/mapr/kafka/kafka-2.1.1.0.202009090438/config/
connect-console-sink.properties connect-distributed.properties
connect-file-source.properties connect-standalone.properties
connect-console-source.properties connect-file-sink.properties
connect-log4j.properties
```

### Kafka Schema Registry

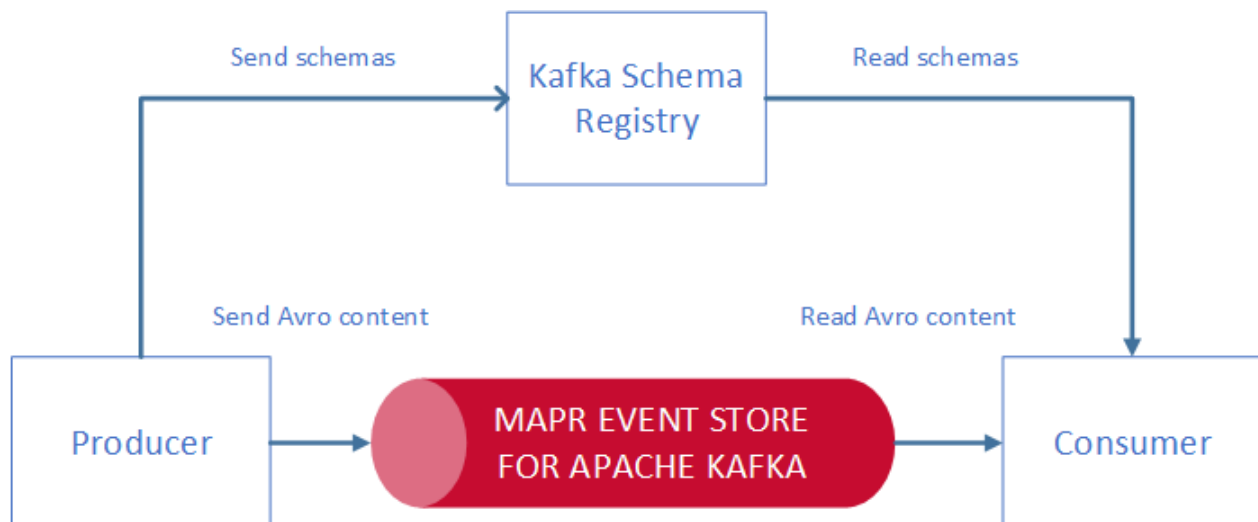

Kafka Schema Registry provides a RESTful interface for storing and retrieving schemas.

Schema Registry can store and retrieve Avro schemas.

Starting in version 6.0.0, Schema Registry can store and retrieve Avro, JSON Schema, and Protobuf schemas.

When you implement Kafka Schema Registry for your data schemas, they can self-evolve for compatibility with downstream consumers.

Kafka Schema Registry acts as a standalone serving layer for metadata, interacting with both the producer and consumer. It stores schemas for keys and values of records.

Kafka Schema Registry enables you to perform the following tasks:

- Store a versioned history of all schemas.
- Provide multiple compatibility settings.
- Support schema evolution according to the configured compatibility settings and the expanded support for the schema format.
- Provide serializers that interface with Kafka clients and manage schema storage and retrieval for Kafka messages that are sent in one of the supported schema formats.
- Develop your own custom formats to use with this interface.

You can also perform these tasks:

- List schemas by subject and also list all versions of a subject (schema).
- Retrieve a schema by version or ID.
- Retrieve the latest version of a schema.
- Verify that a schema is compatible with a certain version.

### Architecture

Kafka Schema Registry is designed to be distributed with a single master architecture. ZooKeeper coordinates the master election, based on the configuration. Kafka-coordinated master election is not currently supported.

HPE Ezmeral Data Fabric Event Streams is designed to be the durable backend for schema registry, providing a write-ahead change log for the state of schema registry and the schemas it contains.

### Interoperability

Kafka Schema Registry can interface with the following components:

- Kafka Client (producer, consumer APIs)
- KStreams
- KSQL
- Kafka Connect
- Kafka REST

### Performance and Scalability Impact

You can improve performance by decreasing the size of the message payload. Without Kafka Schema Registry, the message payload contains the user data and the schema metadata. With the Kafka Schema Registry, the message payload contains the user data and only the schema ID that is unique for each schema.

For scalability, you can launch Kafka Schema Registry on several nodes.

### For More Information

- [Installing Kafka Schema Registry](#)
- [Confluent Schema Registry documentation](#)

### Building and Deploying Kafka Schema Registry

To build and deploy Kafka Schema Registry with Maven, you must first install development versions of Kafka `common` and `rest-utils` utilities.

You can run Kafka Schema Registry instances on several cluster nodes. One node is the primary node and the other ones are secondary nodes.

Kafka Schema Registry requires ZooKeeper and HPE Ezmeral Data Fabric Event Streams.

The REST interface to schema registry includes a built-in Jetty server. The wrapper scripts `bin/schema-registry-start` and `bin/schema-registry-stop` are the recommended methods for starting and stopping the service.

In Apache Kafka, a schema is produced when:

- A message is produced and there is no equivalent schema in the schema registry
- A schema is created for key or value portion of the message

The associated schema subject is a “topic-key”:

- Each schema is associated with a version
- Every schema gets a globally unique ID

The consumer gets the messages’ schema using the schema ID:

```
$ curl -X GET http://localhost:8087/schemas/ids/1
{"schema": "\"string\""}

```

You can also query a schema for a given topic using the associated schema subject. For example, for `topic1` (for either key or value), `schema`, `all`, `latest`, or `specific` schema versions can be queried using the following REST commands:

```
$ curl -X GET http://localhost:8087/subjects/topic1-value/versions
[1]
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}

```

For a complete list of supported APIs, see [Confluent Schema Registry API Reference](#).

### Kafka Schema Registry Limitations

Describes the limitations related to the Kafka Schema Registry.

- **No Replication Support**

Replication for Kafka Schema Registry is not supported.

- **Manually Configure Kafka REST, KSQL, and Kafka Connect to work with Schema Registry**

You must manually modify the Kafka REST, KSQL, and Kafka Connect configuration files if you want them to work with the Schema Registry.

### Kafka Schema Registry Security

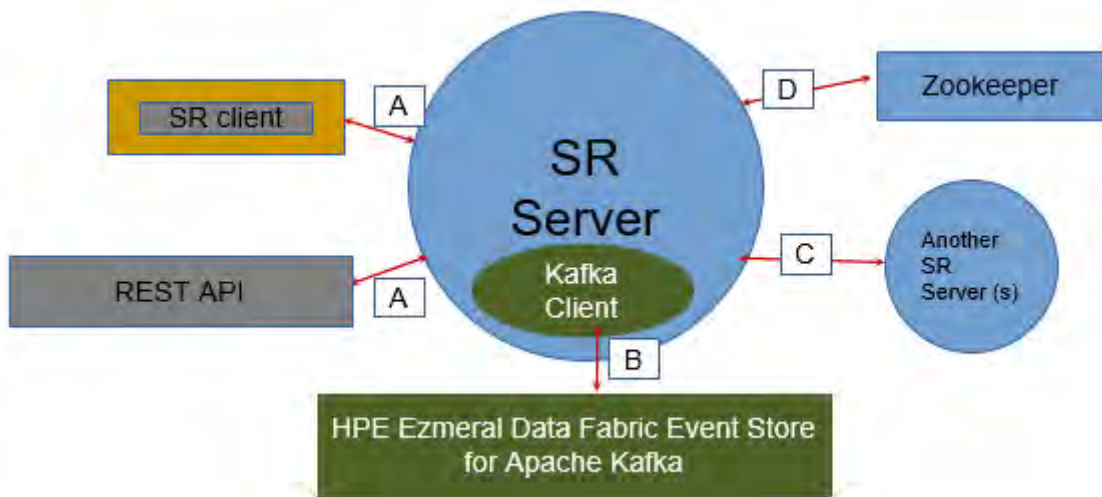

Describes security mechanisms for Kafka Schema Registry.

By default, Schema Registry is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, impersonation, and authorization for Schema Registry. For encryption, SSL/TLS protocols are supported.

If you install Schema Registry in an insecure cluster, you can enable security through security parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file, as described in [Security Parameters](#) on page 4160.

**Schema Registry Communication Paths**

The following image depicts the Schema Registry communication paths:

The following table lists the supported security mechanisms for the Schema Registry communication paths:

**Note:** Path B does not have a network connection and therefore does not need to be secured. However, impersonation works seamlessly for this path through Schema Registry Server.

| Security Features     | Supported Mechanisms                     | Communication Paths Secured                           |
|-----------------------|------------------------------------------|-------------------------------------------------------|
| <b>Authentication</b> | Data Fabric SASL (ticket-based security) | D – Schema Registry Server and ZooKeeper              |
|                       |                                          | A - Schema Registry Client and Schema Registry Server |
|                       | Basic (PAM)                              | C – Schema Registry Server and Schema Registry Server |
|                       |                                          | A - Schema Registry Client and Schema Registry Server |
| <b>Encryption</b>     | Data Fabric SASL (ticket-based security) | C – Schema Registry Server and Schema Registry Server |
|                       |                                          | A - Schema Registry Client and Schema Registry Server |
|                       | SSL/TLS                                  | D - Schema Registry Server and ZooKeeper              |
|                       |                                          | C - Schema Registry Server and Schema Registry Server |
| <b>Authorization</b>  | Based on filesystem permissions.         | A - Schema Registry Client and Schema Registry Server |
| <b>Impersonation</b>  | User impersonation                       | A - Schema Registry Client and Schema Registry Server |

|                 |               |                                                               |
|-----------------|---------------|---------------------------------------------------------------|
|                 |               | <b>B</b> – Schema Registry Server to Streams for Apache Kafka |
|                 |               | <b>C</b> - Schema Registry Server and Schema Registry Server  |
| <b>Auditing</b> | Not supported | --                                                            |

### Kafka Schema Registry Configuration

Describes how to configure the Kafka Schema Registry for HPE Ezmeral Data Fabric Event Store.

Set the Schema Registry configuration parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file.

**schema.registry.service.id**

This parameter indicates the ID of the schema registry service. The default setting for this parameter is `default_`.

See [Schema Registry Configuration Options](#) for additional Schema Registry parameters.

By default, the Schema Registry service runs on port 8087.

#### Security Parameters

Describes Schema Registry security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Schema Registry REST API clients and the Schema Registry Server. In secure clusters, Schema Registry is secured by default. In insecure clusters, you can enable security through the security parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file.

**Requirement:** Before you configure Schema Registry security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table lists the Schema Registry security parameters:

| Parameter                        | Description                                                                                                                                                                                            | Type    | Default        |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|----------------|
| authorization.enable             | Set 'true' or 'false' to enable or disable authorization for Schema Registry service. See <a href="#">Schema Registry Authorization</a> on page 4162.                                                  | boolean | false          |
| authentication.cookie.expiration | Authentication cookie expiration time in seconds.                                                                                                                                                      | long    | 7200 (2 hours) |
| authentication.enable            | Whether or not to enable authentication.                                                                                                                                                               | boolean | false          |
| impersonation.enable             | Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See <a href="#">Schema Registry Impersonation</a> on page 4163.                | boolean | false          |
| listeners                        | Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8087</code> | list    | none           |

|                                       |                                                                                                                                                                                                                                                                                                                                                            |         |                                                                                                                                       |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------|
| ssl.cipher.suites                     | A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.                                                                                                                                                                                                                                                      | list    | none                                                                                                                                  |
| ssl.cipher.suites.exclude             | A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.                                                                                                                                                                                                                                                  | list    | <ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul> |
| ssl.client.auth                       | Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.                                                                                                                                                                                                                                                         | boolean | false                                                                                                                                 |
| ssl.disabled.protocols                | The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.                                                                                                                                                                                                                                                            | list    | <ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>                                                          |
| ssl.enabled.protocols                 | The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.                                                                                                                                                                                                                      | list    | empty                                                                                                                                 |
| ssl.endpoint.identification.algorithm | The endpoint identification algorithm to validate the server hostname using the server certificate.<br>IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.                                                          | string  | none                                                                                                                                  |
| ssl.key.password                      | The password of the private key in the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file. <b>Note:</b> If the <code>ssl-client.xml</code> file is changed, Schema Registry must be restarted. | string  | empty                                                                                                                                 |
| ssl.keymanager.algorithm              | The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.                                                                                                                                                                                                                                                     | string  | empty                                                                                                                                 |

|                            |                                                                                                                                                                                                                                                                                                         |         |       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------|
| ssl.keystore.location      | Location of the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. <b>Note:</b> If the ssl-client.xml file is changed, Schema Registry must be restarted.            | string  | empty |
| ssl.keystore.password      | The store password for the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. <b>Note:</b> If the ssl-client.xml file is changed, Schema Registry must be restarted. | string  | empty |
| ssl.keystore.type          | The type of keystore file.                                                                                                                                                                                                                                                                              | string  | JKS   |
| ssl.protocol               | The SSL protocol used to generate the SslContextFactory.                                                                                                                                                                                                                                                | string  | TLS   |
| ssl.provider               | The SSL security provider name. Leave blank to use Jetty's default.                                                                                                                                                                                                                                     | string  | none  |
| ssl.trustmanager.algorithm | The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.                                                                                                                                                                                                | string  | none  |
| ssl.truststore.location    | Location of the trust store. Required only to authenticate HTTPS clients.                                                                                                                                                                                                                               | string  | empty |
| ssl.truststore.password    | The store password for the trust store file.                                                                                                                                                                                                                                                            | string  | empty |
| ssl.truststore.type        | The type of trust store file.                                                                                                                                                                                                                                                                           | string  | JKS   |
| ssl.trustallcerts.enable   | Set to true if you want to disable certificates verification.                                                                                                                                                                                                                                           | boolean | false |
| headers.file               | The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.                                                                                                                                                      | string  | empty |

### *Schema Registry Authorization*

Describes authorization for Kafka Schema Registry.

In secure clusters, authorization is enabled by default. In insecure clusters, authorization is disabled by default.

You can enable or disable authorization for the Schema Registry in the `<schema-registry-dir>/etc/schema-registry/schema-registry.properties` file through the following option:

```
authorization.enable=[true|false]
```

## Permissions

Permissions grant access to internal data in the Schema Registry, such as schemas, subjects, and server configurations. *Read* permission grants access to view data. *Modify* permission grants access to add, update, and remove data.

The following sections describe operations that require *read* and *modify* access.

**Note:** To avoid any unexpected behaviours when using Schema Registry with KSQL, Kafka Rest, Kafka Connect, or custom Java applications, both *read* and *modify* permissions are required.

## REST API Operations that Require Read Access

|                                                                                     |                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GET</b> /schemas/ids/{int: id}                                                   | Get the schema string identified by the input ID.                                                                                                                                                                |
| <b>GET</b> /subjects/                                                               | Get a list of versions registered under the specified subject.                                                                                                                                                   |
| <b>GET</b> /subjects/(string: subject)/versions/(versionId: version)                | Get a specific version of the schema registered under this subject.                                                                                                                                              |
| <b>GET</b> /subjects/(string: subject)/versions/(versionId: version)/schema         | Get the avro schema for the specified version of this subject.                                                                                                                                                   |
| <b>GET</b> /config                                                                  | Get global compatibility level.                                                                                                                                                                                  |
| <b>GET</b> /config/(string: subject)                                                | Get compatibility level for a subject.                                                                                                                                                                           |
| <b>POST</b> /subjects/(string: subject)                                             | Check if a schema has already been registered under the specified subject. If so, this returns the schema string along with its globally unique identifier, its version under this subject and the subject name. |
| <b>POST</b> /compatibility/subjects/(string: subject)/versions/(versionId: version) | Test input schema against a particular version of a subject's schema for compatibility.                                                                                                                          |

## REST API Operations that Require Modify Access

|                                                                         |                                                                                     |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>DELETE</b> /subjects/(string: subject)                               | Deletes the specified subject and its associated compatibility level if registered. |
| <b>POST</b> /subjects/(string: subject)/versions                        | Register a new schema under the specified subject.                                  |
| <b>DELETE</b> /subjects/(string: subject)/versions/(versionId: version) | Deletes a specific version of the schema registered under this subject.             |
| <b>PUT</b> /config                                                      | Update global compatibility level.                                                  |
| <b>PUT</b> /config/(string: subject)                                    | Update compatibility level for the specified subject.                               |

### *Schema Registry Impersonation*

Describes impersonation for Kafka Schema Registry.

Impersonation authorizes the impersonated user to perform permission-sensitive operations on the Schema Registry. In secure clusters, impersonation is enabled by default. In insecure clusters, impersonation is disabled by default.

**Requirement:** For impersonation to work, Schema Registry authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands

run as the authenticated user instead of the Schema Registry principal. The Schema Registry principal is the user that started the Schema Registry server.

You can enable or disable impersonation for the Schema Registry in the `<schema-registry-client>/etc/schema-registry/schema-registry.properties` file through the following option:

```
impersonation.enable=[true|false]
```

### Related concepts

[Schema Registry Authorization](#) on page 4162

Describes authorization for Kafka Schema Registry.

### Kafka Schema Registry Use Cases

Describes typical use cases to register and query a schema and serialize and deserialize data.

#### Use Case 1: Registering and Querying a Schema for a Kafka Topic

While Kafka topics do not have a schema, having an external store that tracks this metadata for a given Kafka topic helps answer the following questions:

- What are the different events in any given Kafka topic?
- What can I put into a given Kafka topic?
- Do all Kafka events have a similar type of schema?
- How do I parse and use the data in a given Kafka topic?

#### Sample workflow code:

The following sample commands register and query a schema in a Kafka topic:

```
Register a new version of a schema under the subject "Kafka-key"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
 --data '{"schema": "{\"type\": \"string\"}'}' \
 http://localhost:8087/subjects/Kafka-key/versions
 {"id":1}

Register a new version of a schema under the subject "Kafka-value"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
 --data '{"schema": "{\"type\": \"string\"}'}' \
 http://localhost:8087/subjects/Kafka-value/versions
 {"id":1}

List all subjects
$ curl -X GET http://localhost:8087/subjects
 ["Kafka-value", "Kafka-key"]

List all schema versions registered under the subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions
 [1]

Fetch a schema by globally unique id 1
$ curl -X GET http://localhost:8087/schemas/ids/1
 {"schema": "\"string\""}

```

```
Fetch version 1 of the schema registered under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
 {"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}
Fetch the most recently registered schema under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
 {"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}

```

## Use Case 2: Serializing and Deserializing Data in a Kafka Topic

Schema Registry 5.1.2 works with the Avro format only. Schema Registry 6.0.0 works with the Avro format and also JSON Schema and Protobuf formats.

In addition to storing the schema metadata for a topic, Kafka Schema Registry also provides mechanisms for reading and writing data to a Kafka topic in supported formats.

You can plug the appropriate Serializer into the KafkaProducer to send messages to Kafka. A Serializer is available for each of the supported formats.

For Avro, use the `KafkaAvroSerializer`.

For JSON Schema, use the `KafkaJsonSchemaSerializer`.

For Protobuf, use the `KafkaProtobufSerializer`.

Currently, primitive types of `null`, `Boolean`, `Integer`, `Long`, `Float`, `Double`, `String`, `byte[]`, and the complex `IndexedRecord` type are supported.

Sending data of other types to `KafkaAvroSerializer` causes a `SerializationException` to occur. Typically, `IndexedRecord` is used for the value of the Kafka message. If used, the key of the Kafka message is often of one of the primitive types.

For example, when sending a message to a topic `t`, the schema for the key and the value is automatically registered in the Kafka Schema Registry under the subject `t-key` and `t-value`, respectively, if the compatibility test passes. The only exception is when the null type is never registered in the Kafka Schema Registry.

For consuming messages from a Kafka topic, the deserializer can be plugged analogically to the serializer.

## Use Case 3: Supporting KSQL Streams or Tables in Supported formats

KSQL requires that you use the Kafka Schema Registry to create KSQL Streams or Tables in supported formats.

Schema Registry supports Avro format. Specify `VALUE_FORMAT='AVRO'` to work with topics that contain messages in Avro format.

Starting in version 6.0.0, Schema Registry supports JSON Schema and Protobuf in addition to Avro. For JSON Schema and Protobuf, specify either `VALUE_FORMAT='JSON_SR'` or `VALUE_FORMAT='PROTOBUF'` to work with topics that contain messages in JSON Schema or Protobuf format.

### Sample workflow code:

The following commands create and register a schema using an Avro console producer:

```
Create a stream
$ maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p
Use Avro console producer to create and register a schema

```

```

/sample-stream:pageviews-avro-topic

CREATE STREAM pageviews WITH (KAFKA_TOPIC='pageviews-avro-topic',
VALUE_FORMAT='AVRO');

CREATE TABLE users WITH (KAFKA_TOPIC='users-avro-topic',
VALUE_FORMAT='AVRO',
KEY='userid');

```

### Managing Kafka Schema Registry

Describes how to manage the internal stream for Kafka Schema Registry.

#### Schema Registry Internal Stream

By default, the `schema-registry-internal-stream` topic stores the schemas.

The `schema-registry-internal-stream` topic is located in `/apps/schema-registry/schema-registry-internal-stream`. The `kafkastore.stream` property in the `SR_CONF_DIR/schema-registry.properties` file sets the internal stream topic.

By default, the `kafkastore.stream` property is set to `/apps/schema-registry/schema-registry-internal-stream`.

The internal stream is automatically created if it does not already exist. If the internal stream already exists and has the same permissions as the default, the system returns a warning. If `kafkastore.stream` is set to a value other than the default, the system returns an error if the stream does not exist. You must explicitly set permissions on the stream you designate as the Schema Registry internal stream.

You can use Warden and `/opt/mapr/server/configure.sh` to manage and configure Kafka Schema Registry. Any time you change Schema Registry configurations, run `configure.sh` for changes to take effect.

#### Secure Cluster Default Permissions on the Internal Stream

By default, the internal stream is readable by all the users and writable only by the cluster administrator. For secure clusters, the default permissions are:

- `-produceperm u:$CLUSTER_ADMIN`
- `-consumeperm p`
- `-topicperm u:$CLUSTER_ADMIN`

The cluster admin is typically `mapr` or the value set for `MAPR_USER`.

#### Insecure Cluster Default Permissions on the Internal Stream

The stream has both read and write permissions for all users. The default permissions can be modified by means of the `maprcli stream` API. For insecure clusters, the default permissions are:

- `-produceperm p`
- `-consumeperm p`
- `-topicperm p`

#### Log Compaction for the Schema Registry Internal Stream

Log compaction is the process of purging messages previously published to a topic partition while retaining the latest version. Log compaction for the Schema Registry internal stream is enabled by default.

-  **Important:** Log compaction requires a gateway on the same cluster as the Schema Registry internal stream. Also, TTL should be disabled because it can interfere with log compaction.

### Installing a Gateway

Run the command appropriate for your system:

- RedHat/CentOS

```
yum install mapr-gateway
```

- Ubuntu

```
apt-get install mapr-gateway
```

- SLES

```
zypper install mapr-gateway
```

### Related concepts

[Log Compaction](#) on page 604

Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record.

### Related information

[Preparing Clusters for Log Compaction](#) on page 1257

Describes how to prepare your environment so you can use log compaction.

### Enabling High Availability for Kafka Schema Registry

You can enable high availability by installing multiple instances of schema registry on the same cluster.

One node in the cluster acts as the primary instance. Only the primary instance can publish writes to the underlying Kafka log. The primary node can also manage read requests.

All other secondary nodes manage only read requests. These nodes serve registration requests indirectly by forwarding them to the current primary node and returning any response supplied by the primary node.

1. Install schema registry on several nodes. For installation instructions, see [Installing Kafka Schema Registry](#).
2. Configure high availability for the ensemble of ZooKeeper nodes. You can find the steps for this in the [open source documentation](#), section Clustered (Multi-Server) Setup.
3. Modify the schema registry configuration file on each node to specify the `kafkastore.connection.url` property with the ZooKeeper nodes that form the HA ensemble.
4. Run the `configure.sh -R` command on each schema registry node.

### Schema Registry Demos

Provides demonstrations for using Kafka Schema Registry to store and retrieve schemas.

The following topics demonstrate how to use Kafka Schema Registry to store and retrieve schemas in the supported formats:

*Kafka Schema Registry Demo for Avro*

Implements a Kafka Schema Registry demo example that stores and retrieves Avro schemas.

## Maven Dependencies

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
 <repository>
 <id>confluent</id>
 <url>http://packages.confluent.io/maven/</url>
 </repository>
 <repository>
 <id>mapr-maven</id>
 <url>https://repository.mapr.com/maven/</url>
 <releases><enabled>true</enabled></releases>
 <snapshots><enabled>true</enabled></snapshots>
 </repository>
</repositories>
```

The following dependencies are needed for Avro and Kafka:

```
<dependency>
 <groupId>org.apache.avro</groupId>
 <artifactId>avro</artifactId>
 <version>1.9.2</version>
</dependency>
<dependency>
 <groupId>io.confluent</groupId>
 <artifactId>kafka-avro-serializer</artifactId>
 <version>5.1.2.0-mapr-700</version>
</dependency>
```

## Creating a Java class that corresponds to the Avro schema

Add the following plugins to the pom.xml file:

- Plugin to build code:

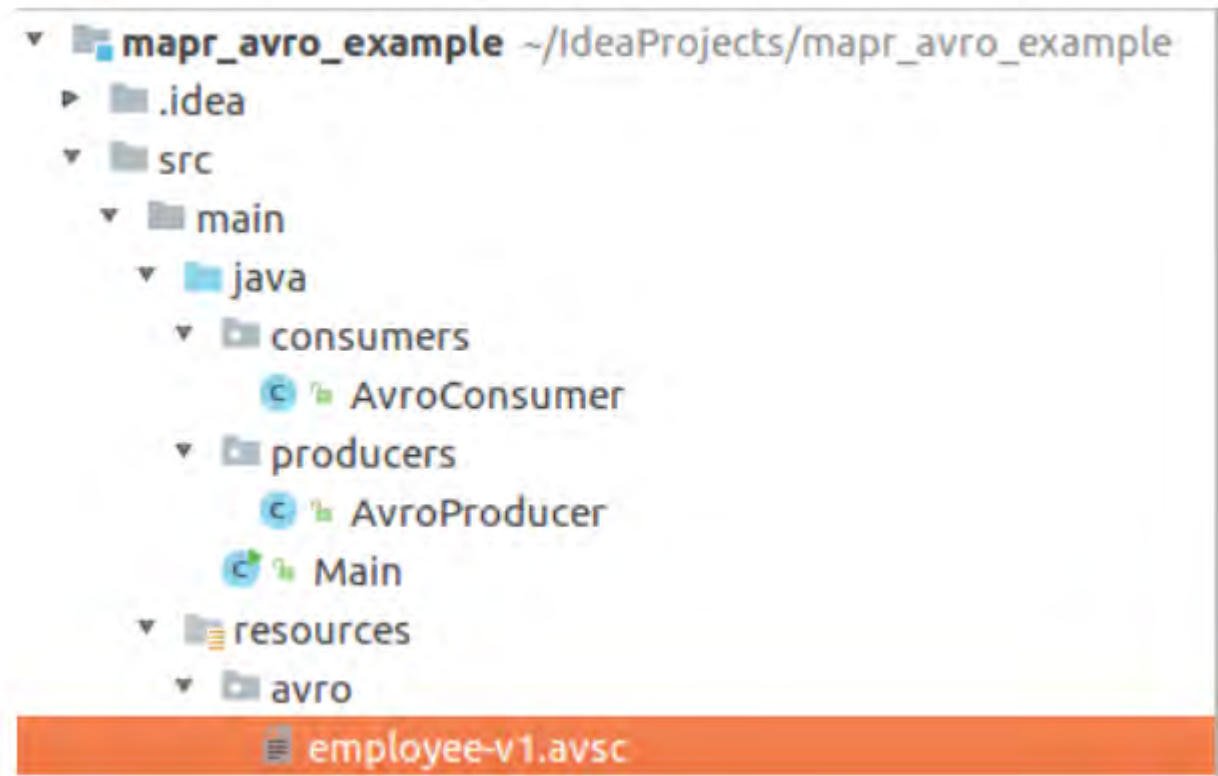

```
<plugin>
 <groupId>org.apache.avro</groupId>
 <artifactId>avro-maven-plugin</artifactId>
 <version>1.8.2</version>
 <executions>
 <execution>
 <phase>generate-sources</phase>
 <goals>
 <goal>schema</goal>
 <goal>protocol</goal>
 <goal>idl-protocol</goal>
 </goals>
 <configuration>
 <sourceDirectory>${project.basedir}/src/main/resources/avro/</
sourceDirectory>
 <stringType>String</stringType>
 <createSetters>>false</createSetters>
 <enableDecimalLogicalType>>true</enableDecimalLogicalType>
 <fieldVisibility>private</fieldVisibility>
 </configuration>
 </execution>
 </executions>
</plugin>
```

- Plugin to force the discovery of the generated classes:

```
<plugin>
 <groupId>org.codehaus.mojo</groupId>
 <artifactId>build-helper-maven-plugin</artifactId>
 <version>3.0.0</version>
 <executions>
 <execution>
 <id>add-source</id>
 <phase>generate-sources</phase>
 <goals>
 <goal>add-source</goal>
 </goals>
 <configuration>
 <sources>
 <source>target/generated-sources/avro</source>
 </sources>
 </configuration>
 </execution>
 </executions>
</plugin>
```

- Create a file with filename extension `.avsc` in the `src/main/resources` directory.

An example of an Avro schema is as follows:

```
{
 "namespace": "com.example",
 "type": "record",
 "name": "Employee",
 "doc": "Represents an Employee at a company",
 "fields": [
 { "name": "firstName", "type": "string", "doc": "The persons given name" },
],
}
```

```

 {"name": "lastName", "type": "string"},
 {"name": "age", "type": "int", "default": -1},
 {"name": "emails", "default": [], "type": {"type": "array", "items":
"string"}},
 {"name": "phoneNumber", "type": "string"}
]
}

```

The `Employee.class` Java class is auto-generated in the `target/classes/com/example` directory after executing the following commands:

```

$ mvn clean
$ mvn package

```

You can use this class in your program after performing these steps.

### Creating an Avro Producer

1. Import the following properties for the Kafka Producer:

```

import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroSerializer;
import io.confluent.kafka.serializers.KafkaAvroSerializerConfig;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.ArrayList;
import java.util.List;
import java.util.Properties;

```

2. Configure the following properties for Event Data Streams:

```

Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
 IntegerSerializer.class.getName());

// Configure the KafkaAvroSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
 KafkaAvroSerializer.class.getName());

//Schema registry location.
properties.setProperty(KafkaAvroSerializerConfig.SCHEMA_REGISTRY_URL_CONF
IG,
 "http://localhost:8087");

KafkaProducer<Integer, Employee> producer =
 new KafkaProducer<>(properties);

```

- The following code sends  $n$  different objects of class `Employee.java` to the topic `avro_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
Employee employee;

for (int i = 0; i < n; i++) {

 List<String> emails = new ArrayList<>();
 for (int j = 0; j < i; j++) {
 emails.add("john" + j + ".doe" + i + "@mail.com");
 }

 employee = Employee.newBuilder()
 .setFirstName("John" + i)
 .setLastName("Doe")
 .setAge(i + 5)
 .setEmails(emails)
 .setPhoneNumber("+1-202-555-" + i + i + i + i)
 .build();

 ProducerRecord<Integer, Employee> record =
 new ProducerRecord(topic, i, employee);

 producer.send(record, (recordMetadata, e) -> {
 if (e == null) {
 System.out.println("Success! ");
 System.out.println(recordMetadata.toString());
 } else {
 e.printStackTrace();
 }
 });
}

producer.flush();
producer.close();
```

## Creating an Avro Consumer

- Import the following properties for the Kafka Consumer:

```
import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroDeserializer;
import io.confluent.kafka.serializers.KafkaAvroDeserializerConfig;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.util.Collections;
import java.util.Properties;
```

2. The properties to configure are similar to the Kafka producer, only Deserializers must be used instead of Serializers. Add one more property called `KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG`:

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
 IntegerDeserializer.class.getName());

//Use Kafka Avro Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
 KafkaAvroDeserializer.class.getName());

//Use Specific Record or else you get Avro GenericRecord.
properties.put(KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG,
 "true");

//Schema registry location.
properties.put(KafkaAvroDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
 "http://localhost:8087");

KafkaConsumer<Integer, Employee> consumer =
 new KafkaConsumer<>(properties);
```

3. The following code reads objects of the `Employee.java` class from the `avro_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
consumer.subscribe(Collections.singletonList(topic));

try {
 while (true) {
 ConsumerRecords<Integer, Employee> records =
 consumer.poll(Duration.ofMillis(100));
 records.forEach(record -> {

 Employee employeeRecord = record.value();

 System.out.printf("%s %d %d %s \n", record.topic(),
 record.partition(), record.offset(), employeeRecord);
 });
 }
} finally {
 consumer.close();
}
```

### *Kafka Schema Registry Demo for JSON Schema*

Implements a Kafka Schema Registry demo example that stores and retrieves schemas in JSON Schema format.

### **Maven Dependencies**

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
 <repository>
 <id>confluent</id>
 <url>http://packages.confluent.io/maven/</url>
 </repository>
 <repository>
 <id>mapr-maven</id>
```

```

 <url>https://repository.mapr.com/maven/</url>
 <releases><enabled>true</enabled></releases>
 <snapshots><enabled>true</enabled></snapshots>
 </repository>
</repositories>

```

The following dependencies are needed for JSON Schema and MapR Kafka:

```

<dependency>
 <groupId>com.fasterxml.jackson.core</groupId>
 <artifactId>jackson-annotations</artifactId>
 <version>2.10.5</version>
</dependency>

<dependency>
 <groupId>io.confluent</groupId>
 <artifactId>kafka-json-schema-serializer</artifactId>
 <version>6.0.0.0-eep-800</version>
</dependency>

```

### Create a Java class that corresponds to JSON Schema

Create a Java class that includes Jackson annotations, for example:

```

import com.fasterxml.jackson.annotation.JsonProperty;

public class User {
 @JsonProperty
 public String firstName;
 @JsonProperty
 public String lastName;
 @JsonProperty
 public short age;
 public User() {}
 public User(String firstName, String lastName, short age) {
 this.firstName = firstName;
 this.lastName = lastName;
 this.age = age;
 }
 public String toString() {
 return String.format("first name: " + firstName
 + "; last name: " + lastName + "; age: " + age);
 }
}

```

### Create a JSON Schema Producer

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

## 2. Configure the following properties for the Event Data Streams:

```
Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
 IntegerSerializer.class.getName());

// Configure the KafkaJsonSchemaSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
 KafkaJsonSchemaSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaJsonSchemaSerializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
 "http://localhost:8087");

KafkaProducer<Integer, User> producer =
 new KafkaProducer<>(properties);
```

## 3. Use the following code to send n different objects of class User.java to the topic json-schema\_example in the /sample-stream stream:

```
String topic = "/sample-stream:json-schema_example";

for (int i = 0; i < n; i++) {
 User user = new User("John" + i, "Doe", (short) (i + 30));

 ProducerRecord<Integer, User> record =
 new ProducerRecord(topic, i, user);

 producer.send(record, (recordMetadata, e) -> {
 if (e == null) {
 System.out.println("Success!");
 System.out.println(recordMetadata.toString());
 } else {
 e.printStackTrace();
 }
 });
}

producer.flush();
producer.close();
```

## Create a JSON Schema Consumer

### 1. Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
 IntegerDeserializer.class.getName());

//Use Kafka JSON Schema Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
 KafkaJsonSchemaDeserializer.class.getName());

//A class that the message value should be deserialized to.
properties.put(KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE,
 User.class.getName());

//Schema registry location.
properties.put(KafkaJsonSchemaDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
 "http://localhost:8087");

KafkaConsumer<Integer, User> consumer =
 new KafkaConsumer<>(properties);
```

3. Use the following code to read objects of the `User.java` class from the `json-schema_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:json-schema_example";
consumer.subscribe(Collections.singletonList(topic));

try {
 while (true) {
 ConsumerRecords<Integer, User> records =
 consumer.poll(Duration.ofMillis(100));

 records.forEach(record -> {

 User userRecord = record.value();

 System.out.printf("%s %d %d %s \n", record.topic(),
 record.partition(), record.offset(),
 userRecord);
 });
 }
} finally {
 consumer.close();
}
```

### *Kafka Schema Registry Demo for Protobuf*

Implements a Kafka Schema Registry demo example that stores and retrieves Protobuf schemas.

### **Maven Dependencies**

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
 <repository>
 <id>confluent</id>
 <url>http://packages.confluent.io/maven/</url>
 </repository>
```

```

<repository>
 <id>mapr-maven</id>
 <url>https://repository.mapr.com/maven/</url>
 <releases><enabled>true</enabled></releases>
 <snapshots><enabled>true</enabled></snapshots>
</repository>
</repositories>

```

The following dependencies are needed for Protobuf and MapR Kafka:

```

<dependency>
 <groupId>com.google.protobuf</groupId>
 <artifactId>protobuf-java</artifactId>
 <version>3.17.3</version>
</dependency>

<dependency>
 <groupId>io.confluent</groupId>
 <artifactId>kafka-protobuf-serializer</artifactId>
 <version>6.0.0.0-eep-800</version>
</dependency>

```

### Create a Java class that corresponds to the Protobuf schema

Add the following plugin to the pom.xml file:

```

<plugin>
 <groupId>com.github.os72</groupId>
 <artifactId>protoc-jar-maven-plugin</artifactId>
 <version>3.11.4</version>
 <executions>
 <execution>
 <phase>generate-sources</phase>
 <goals>
 <goal>run</goal>
 </goals>
 <configuration>
 <inputDirectories>
 <include>src/main/resources/</include>
 </inputDirectories>
 <outputTargets>
 <outputTarget>
 <type>java</type>
 <addSources>none</addSources>
 <outputDirectory>src/main/java/</outputDirectory>
 </outputTarget>
 </outputTargets>
 </configuration>
 </execution>
 </executions>
</plugin>

```

Create a file with the .proto extension in the src/main/resources/proto directory. For example, person.proto. An example of a Protobuf schema is as follows:

```

syntax = "proto3";
package io.demo.example;
option java_outer_classname = "PersonImpl";

message Person {
 int32 id = 1;

```

```

string firstName = 2;
string lastName = 3;
string email = 4;
}

```

The `PersonImpl.class` Java class is auto-generated in the `src/main/java/io/demo/example` directory after running the following commands:

```

$ mvn clean
$ mvn package

```

You can use this class in your program to manage the class `Person.class`.

### Create a Protobuf Producer

To create a Protobuf producer:

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

2. Configure the following properties for the Event Data Streams:

```

Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
 IntegerSerializer.class.getName());

// Configure the KafkaProtobufSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
 KafkaProtobufSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaProtobufSerializerConfig.SCHEMA_REGISTRY_URL_
CONFIG,
 "http://localhost:8087");

KafkaProducer<Integer, Person> producer =
 new KafkaProducer<>(properties);

```

- Use the following code to send  $n$  different objects of class `Person.java` to the topic `proto_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:proto_example";
Person person;

for (int i = 0; i < n; i++) {
 Person person = Person.newBuilder()
 .setId(i)
 .setFirstName("John")
 .setLastName("Doe")
 .setEmail("john" + i + ".doe@mail.com")
 .build();

 ProducerRecord<Integer, Person> record =
 new ProducerRecord(topic, i, person);

 producer.send(record, (recordMetadata, e) -> {
 if (e == null) {
 System.out.println("Success! ");
 System.out.println(recordMetadata.toString());
 } else {
 e.printStackTrace();
 }
 });
}

producer.flush();
producer.close();
```

### Create a Protobuf Consumer

To create a Protobuf consumer:

- Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
 IntegerDeserializer.class.getName());

//Use Kafka Protobuf Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
 KafkaProtobufDeserializer.class.getName());

//A class generated by Protocol buffers that the message value should be
deserialized to.
properties.put(KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TY
PE,
 Person.class.getName());

//Schema registry location.
properties.put(KafkaProtobufDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG
,
 "http://localhost:8087");

KafkaConsumer<Integer, Person> consumer =
 new KafkaConsumer<>(properties);
```

3. Use the following code to read objects of the `Person.java` class from the `proto_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:proto_example";
consumer.subscribe(Collections.singletonList(topic));

try {
 while (true) {
 ConsumerRecords<Integer, Person> records =
 consumer.poll(Duration.ofMillis(100));

 records.forEach(record -> {

 Person personRecord = record.value();

 System.out.printf("%s %d %d %s \n", record.topic(),
 record.partition(), record.offset(),
 personRecord);
 });
 }
} finally {
 consumer.close();
}
```

### Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

### Related Links

Spark streaming is integrated with HPE Ezmeral Data Fabric Event Streams for Apache Kafka.

- [MapR Event Store For Apache Kafka Clients and Tools](#)

**Prerequisites for Using Structured Streaming in Spark**

To deploy a structured streaming application in Spark, you must create a MapR Streams topic and install a Kafka client on all nodes in your cluster.

*Creating a MapR Streams Topic*

- Create a MapR Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

*Installing a Kafka Client*

- Install a kafka-client on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

**Using Structured Streaming to Create a Word Count Application**

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

*Using Apache Kafka***Scala**

```
val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCount")
 .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.servers", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS STRING)")
 .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split(" ")).groupBy("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
 .outputMode("complete")
 .format("console")
 .option("checkpointLocation", checkpointLocation)
 .start()

query.awaitTermination()
```

**Java**

```
SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructuredKafkaWordCount")
 .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
```

```

Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap
.servers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value
AS STRING)")
 .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
 .outputMode("complete")
 .format("console")
 .start();

query.awaitTermination();

```

## Python

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWor
dCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.ser
vers", bootstrapServers)\
 .option(subscribeType,
topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

```

```
#Run the query that prints the
running counts to the console
query = wordCounts\
 .writeStream\
 .outputMode('complete')\
 .format('console')\
 .start()

query.awaitTermination()
```

### Using MapR Event Store for Apache Kafka

For MapR Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val dfl = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
 "maprdemo:9092").option("subscribe", topic).option("group.id",
 "testgroup").option("startingOffsets",
 "earliest").option("failOnDataLoss",
 false).option("maxOffsetsPerTrigger", 1000).load()
```

### Writing a Structured Spark Stream to HPE Ezmeral Data Fabric Database JSON Table

The example in this section writes a structured stream in Spark to HPE Ezmeral Data Fabric Database JSON table.

To write a structured Spark stream to HPE Ezmeral Data Fabric Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

#### Scala

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
 .writeStream
 .format(MapRDBSourceConfig.Format)
 .option(MapRDBSourceConfig.TablePathOption, "/table/path")
 .option(MapRDBSourceConfig.IdFieldPathOption, "value")
 .option(MapRDBSourceConfig.CreateTableOption, true)
 .option(MapRDBSourceConfig.BulkModeOption, true)
 .option(MapRDBSourceConfig.SampleSizeOption, 1000)
 .outputMode("append")
}
```

**Java**

```

import
com.mapr.db.spark.streaming.MapRDBSourceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
org.apache.spark.sql.streaming.DataStreamReader;
import
org.apache.spark.sql.streaming.DataStreamWriter;
import
org.apache.spark.sql.streaming.StreamingQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
 return df.selectExpr("CAST(value
AS STRING) as _id")
 .writeStream()
 .format(MapRDBSourceConfig
.Format())
 .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
 .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
 .option(MapRDBSourceConfig
.CreateTableOption(), true)
 .option(MapRDBSourceConfig
.BulkModeOption(), true)
 .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
 .outputMode("append");
}

```

**Python**

```

from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
 return df.selectExpr("CAST(value AS
STRING) as _id") \
 .writeStream \
 .format("com.mapr.db.spark.
streaming") \
 .option("checkpointLocation
", checkpoint_dir) \
 .option("tablePath",
table_path) \
 .option("idFieldPath",
"value") \
 .option("createTable",
True) \
 .option("bulkMode", True) \
 .option("sampleSize", 1000)

```

**Writing a Spark Stream Word Count Application to HPE Ezmeral Data Fabric Database**

The example in this section writes a Spark stream word count application to HPE Ezmeral Data Fabric Database.

**Scala**

```

val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCount")
 .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.servers", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS STRING)")
 .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
 .format(MapRDBSourceConfig.Format)
 .option(MapRDBSourceConfig.TablePathOption, resultTable)
 .option(MapRDBSourceConfig.CreateTableOption, true)
 .option(MapRDBSourceConfig.IdFieldPathOption, "value")
 .outputMode("complete")
 .start()

query.awaitTermination()

```

**Java**

```

SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructuredKafkaWordCount")
 .getOrCreate();

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap.servers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value AS STRING)")
 .as(Encoders.STRING());

```

```

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
 .format(MapRDBSourceConfig
.Format())
 .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
 .option(MapRDBSourceConfig
.CreateTableOption(), true)
 .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
 .outputMode("complete");
 .start();

query.awaitTermination();

```

## Python

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWo
rdCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.ser
vers", bootstrapServers)\
 .option(subscribeType,
topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB

```

```

query = wordCounts\
 .writeStream\
 .format("com.mapr.db.spark.streaming") \
 .option("tablePath",
table_path) \
 .option("createTable",
True) \
 .option("idFieldPath",
"value") \
 .outputMode('complete')\
 .start()

query.awaitTermination()

```

## S3 Gateway

The S3 gateway is a service that provides an S3-compatible interface to expose data in HPE Ezmeral Data Fabric as objects. The S3 gateway manages all inbound S3 API requests to put data into and get data out of cloud storage.

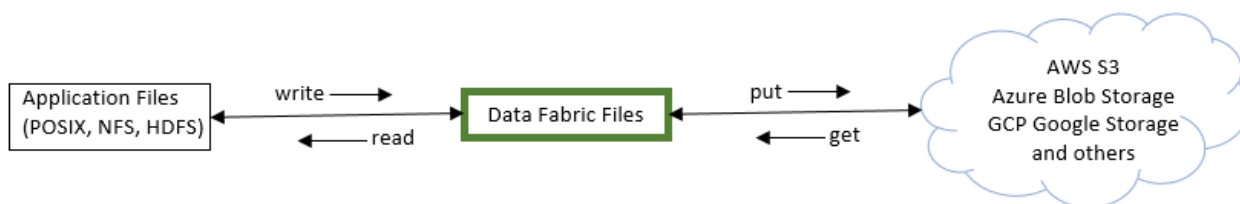

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

The S3 gateway can expose data generated through multiple data protocols, such as NFS, POSIX, S3, and HDFS as objects.

The HPE Ezmeral Data Fabric filesystem stores an object as a file. The file can be of any data type, but must have a unique name as part of the S3 API call. Files can be accessed by the S3 API requests and by HPE Ezmeral Data Fabric file interfaces. Data objects are grouped into a logical container called a bucket. A bucket correlates with a folder in HPE Ezmeral Data Fabric.

The following image shows the flow of data to and from HPE Ezmeral Data Fabric:

You can use the S3 API to create, list, or delete a bucket. You can also use it to get, put, list, or delete a data object within a bucket. The first time the S3 API accesses a file, it generates metadata. Metadata is required to fulfill the API requests.

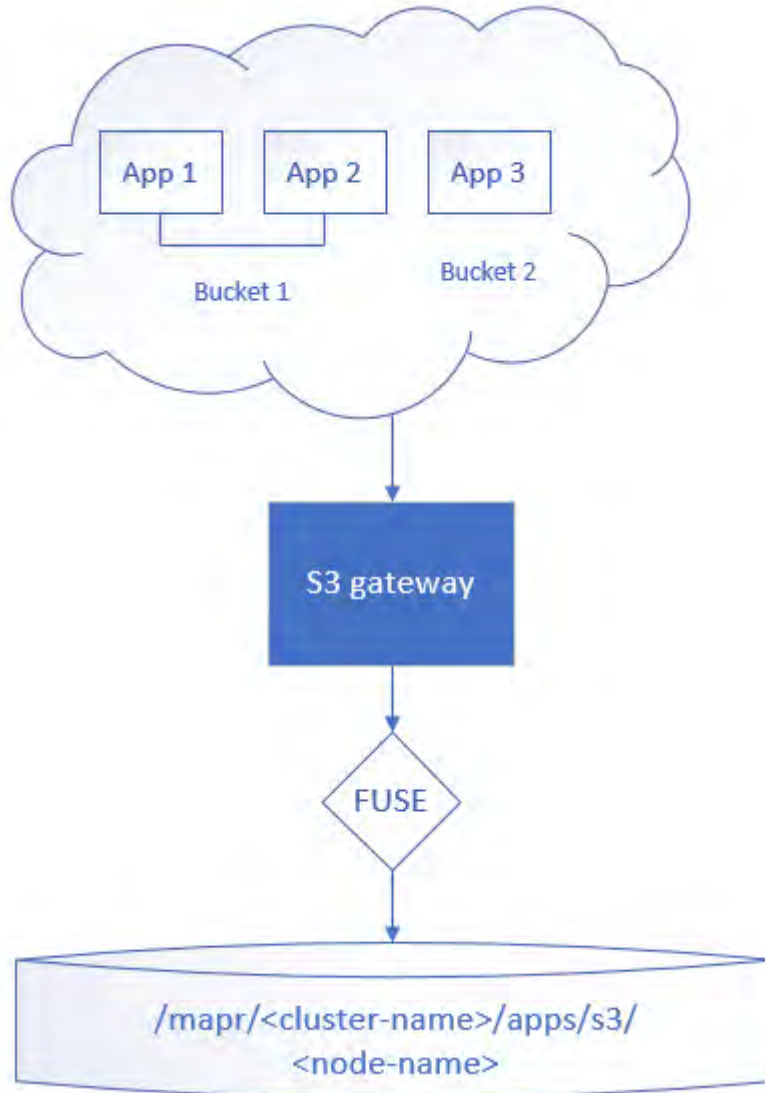

The S3 gateway also supports object notification through HPE Ezmeral Data Fabric Event Streams. See [Using the HPE Ezmeral Data Fabric Event Streams for S3 Bucket Event Notifications](#) on page 4206.

## S3 Deployment Mode

The S3 gateway only supports the *Amazon S3 standalone deployment mode* because each instance of the S3 gateway can only interact with one bucket or set of buckets at a time.

When you use the S3 API in standalone mode, each S3 gateway instance must have its own back-end directory in the HPE Ezmeral Data Fabric filesystem. You can either map a volume mount point to the directory or use the directory path itself. An S3 instance exclusively uses the allocated directory or volume in the filesystem to serve an exclusive set of buckets.

The following deployment scenario shows one S3 gateway per cluster that supports multiple applications and multiple buckets with bucket sharing:

This scenario is useful if you want an application to access multiple buckets without knowing about bucket locations beforehand. The single S3 gateway instance serves all requests without having to partition any buckets.

If you need to migrate buckets to another S3 instance, you can move or copy the buckets to another directory or volume. See [AWS CLI](#). If a bucket does not exist, an application can create a bucket through any S3 gateway; however, the bucket created will only be served through the one gateway.

### Authorization to Access Data

By default, the S3 gateway provides a two-tier authorization model that starts with an S3 bucket policies check at the S3 REST API level, followed by a file permissions check on the HPE Ezmeral Data Fabric.

When an S3 gateway instance receives a request from a tenant to access a bucket or object, it first checks for bucket policies that reference that particular tenant. If the tenant does not have access via the bucket policy, the request fails and no other checks are performed.

If the tenant has access via the bucket policy, the filesystem performs the next check using the mapped UID and GID credentials for the tenant.

[Configuring S3 Gateway](#) on page 4188 describes how to modify the type of authorization, configure tenants and credentials, and secure data.

### High Availability (HA)

S3 gateway 2.0.0 and later supports working from several instances with the same mount folder on different nodes. If several instances use the same mount folder on different nodes, caching in FUSE should be disabled. For more information, see [S3 Gateway Limitations](#) on page 4208.

To implement HA, you must configure a load balancer in front of the S3 gateway instances and make the corresponding changes in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file for all instances.

If a multi-part upload feature is used, the load balancer must hash the request's source and send requests from each unique host to the same node.

After any administrative change to the S3 gateway configuration using the MinIO client (for example, to add new users, groups, policies, or notifications), you must restart all instances manually to avoid collisions on different instances.

- For information about object tiering (archiving files in the cloud), see [Data Tiering](#) on page 425.

### Configuring S3 Gateway

Describes how to configure the S3 gateway.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

EEP 7.1.0 and later supports S3 gateway version 2.1.0 and higher. S3 gateway 2.2.0.0 is available starting in EEP 8.0.0.

Add the S3 gateway `superadmin` and change the deployment mode in the `minio.json` file. After you update and save the file, restart the `objectstore` service.

### Global Configuration

To change the global configuration of the S3 gateway update the configuration file located in `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json`.

The configuration file for S3 gateway 2.1.0 and later differs from previous versions; it includes LDAP, distributed mode, and skip secure verification configuration updates.

### S3 gateway version 2.1.0 and later configuration example

```
{
 "version": "2",
 "fsPath": "/mapr/${cluster}/apps/s3/${node}",
 "deploymentMode": "S3",
 "distributedHosts": "",
 "accessKey": "minioadmin",
 "secretKey": "minioadmin",
 "oldAccessKey": "",
 "oldSecretKey": "",
 "port": "9000",
```

```

 "domain": "",
 "logPath": "/opt/mapr/objectstore-client/objectstore-client-<version>/
logs/minio.log",
 "logLevel": 4,
 "insecureSkipVerify": false,
 "ldap": {
 "serverAddr": "",
 "usernameFormat": "",
 "userDNSearchBaseDN": "",
 "userDNSearchFilter": "",
 "groupSearchFilter": "",
 "groupSearchBaseDn": "",
 "lookUpBindDN": "",
 "lookUpBindPassword": "",
 "stsExpiry": "",
 "tlsSkipVerify": "",
 "serverStartTls": "",
 "serverInsecure": ""
 }
}

```

### S3 gateway version 2.0.x configuration example

```

{
 "fsPath": "/mapr/${cluster}/apps/s3/${node}",
 "deploymentMode": "S3",
 "accessKey": "minioadmin",
 "secretKey": "minioadmin",
 "oldAccessKey": "",
 "oldSecretKey": "",
 "port": "9000",
 "domain": "",
 "logPath": "/opt/mapr/objectstore-client/objectstore-client-2.0.0/logs/
minio.log",
 "logLevel": 4,
 "ldap": {
 "serverAddr": "",
 "usernameFormat": "",
 "usernameSearchFilter": "",
 "groupSearchFilter": "",
 "groupSearchBaseDn": "",
 "usernameSearchBaseDn": "",
 "groupNameAttribute": "",
 "stsExpiry": "",
 "tlsSkipVerify": "",
 "serverStartTls": "",
 "severInsecure": ""
 }
}

```

To change the port and log path requires you to reconfigure Warden for the server node and restart the S3 gateway. Other properties require only an S3 gateway restart.

### Setting the `superadmin` Credentials

You can configure the `superadmin` user name and password with properties `accessKey` and `secretKey`. If you configure the S3 gateway for the first time, then it is enough just to change them. If you would like to change the `superadmin` credentials on an already configured instance, you also have to set previous values `oldAccessKey` to the and `oldSecretKey`.

## Setting the Deployment Mode

The deployment mode sets the type of authorization being used. The default deployment mode is `S3`. To change the deployment mode setting, you can edit the `deploymentMode` parameter in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file.

The S3 gateway supports the following deployment modes:

| Option | Deployment Mode | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1      | FS              | <p>Enforced by filesystem file permissions only. The S3 bucket policy is disabled. Access is granted based on the bucket owner UID and GID (not on read, write, or execute permissions).</p> <ul style="list-style-type: none"> <li>Configuration maps the application key or secret to a data-fabric ID.</li> <li>S3 policy is not used, and the policy check is skipped.</li> <li>Data Fabric file security validates inbound mapped UID and GID to authorize read or write file permissions.</li> </ul> <p>You must <a href="#">Set the Path to Mount the Filesystem</a>.</p> |
| 2      | S3              | <p>Enforced by S3 bucket policy only:</p> <ul style="list-style-type: none"> <li>Access is controlled by the secret access key and the key ID.</li> <li>Read-write permissions and the owner of the file are ignored while granting access.</li> </ul> <p> <b>Important:</b> To prevent unauthorized access to data, upload the corresponding S3 policies after S3 gateway starts.</p>                                                                                                         |

## Setting the Path to Mount the Filesystem

If you use the `FS` deployment mode, you must set the path to mount the file system:

| Node Type   | How to Set the Path                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Server node | <p>In the <code>minio.json</code> file, set the <code>fsPath</code> parameter to the file-system mount path. By default, the path is set to <code>/mapr/&lt;clustername&gt;/apps/s3/&lt;nodename&gt;</code>. If you want to share existing folders with users, set the <code>fsPath</code> parameter to point to the directory with the folders that you want to share. All the folders in the directory to which <code>fsPath</code> points are accessible as buckets.</p> <p> <b>Important:</b> All folders in the parent folder (<code>fsPath</code> parameter) will be accessible as buckets. Set filesystem permissions on folders to prevent unauthorized access to data.</p> |
| Edge node   | <p>If you completed the edge-node installation <a href="#">steps</a>, no action is required. This is because you already set the path to mount the filesystem when you ran the S3 gateway <code>configure.sh</code> script with the <code>--path</code> parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Distributed Mode

S3 gateway 2.1.0 and later supports distributed mode. S3 gateway 2.0.x does not support distributed mode.

Note the following points related to S3 gateway 2.1.0 and later in distributed mode:

- In distributed mode, instances of S3 gateway share user and policy information only, as well as locks between nodes.

- Distributed mode does not include proxy or load balancing in front of instances. You must configure and install proxy and load balancing manually.
- Distributed mode only works for S3 mode.
- Three or more nodes is recommended for S3 gateway in distributed mode. If only one node is active, the node will be in read-only mode.

To enable distributed mode for S3 gateway 2.1.0 and later:

1. Configure S3 gateway 2.1.0 or later on three or more nodes.
2. Disable caching in Fuse clients.
3. On each S3 gateway node, update the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file with the `accessKey`, `secretKey`, and `ldap`. The value for each of these properties must be identical across all the `minio.json` files.
4. On all S3 gateway 2.1.0 or later nodes, verify that the `distributedHosts` property contains the list of nodes with mount paths, for example:

```
"distributedHosts": "http(s)://HOST1:PORT1/MOUNT_PATH1 http(s)://
HOST2:PORT2/MOUNT_PATH2"
```

Note that the mount path on all nodes should target the same folder in the filesystem.

5. If the cluster is secure with self-signed certificates, copy the public certificates for each host to the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/certs/CAs` directory. To ignore validation of the certificates, set `"insecureSkipVerify": true`.

### Setting Virtual Hosting of Buckets

You can enable the virtual hosting of buckets by setting the `domain` property in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` configuration file. For more information, see the Domain section in the [MinIO Server Config Guide](#).

### Setting LDAP Integration

Set LDAP integration in the `ldap` section of the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` configuration file. For descriptions and examples of LDAP integration properties, see [MinIO LDAP documentation](#).

For LDAP integration information, refer to [Integrating S3 Gateway with LDAP/AD](#).

#### S3 gateway 2.1.0 and later

In S3 gateway version 2.1.0, you can only set LDAP integration in S3 mode. In S3 gateway version 2.2.0.0, you can set LDAP integration in S3 or FS mode. LDAP integration in FS mode requires that the user have a primary UID and GID. Note that you cannot assign more than one GID to a user. In FS mode, LDAP integration is handled similarly to internal users. The primary UID and GID for the LDAP user are received and injected inside the request.

```
"ldap": {
 "serverAddr": "localhost:389",
 "usernameFormat":
 "cn=%s,dc=mapr,dc=local",
 "userDNSearchBaseDN": "",
 "userDNSearchFilter": "(cn=%s)",
```

```

"groupSearchFilter" :
"(&(objectclass=group)(member=%s))",
"groupSearchBaseDn" :
"dc=mapr,dc=local",
"lookUpBindDN" : "",
"lookUpBindPassword" : "",
"stsExpiry" : "60h",
"tlsSkipVerify" : "on",
"serverStartTls" : "",
"serverInsecure" : "on"
}

```

### S3 gateway 2.0.x

In S3 gateway version 2.0.x, only S3 mode is supported.

```

"ldap" : {
 "serverAddr" : "10.244.0.11:636",

 "usernameFormat" : "uid=%s,ou=users,dc=example,dc=com",

 "usernameSearchFilter" : "(uid=%s)",
 "groupSearchFilter" : "",

 "groupSearchBaseDn" : "ou=users,dc=example,dc=com",
 "usernameSearchBaseDn" : "",
 "groupNameAttribute" : "",
 "stsExpiry" : "60h",
 "tlsSkipVerify" : "on",
 "serverStartTls" : "",
 "serverInsecure" : "off"
}

```

### LDAP Limitations

- Starting from version 2.2.0.0, S3 gateway supports S3 and FS mode. In previous versions, S3 gateway only supports S3 mode (and does not support FS mode).
- LDAP/AD integration does not work with Hadoop and Spark because the HPE Ezmeral Data Fabric implementation of Hadoop and Spark does not support sessionToken.
- In S3 gateway 2.0.0, the MINIO\_IDENTITY\_LDAP\_SERVER\_STARTTLS property is not supported, and its value in the configuration file is ignored.

### About Credentials

In the S3 world, credentials represent the application and not the identity of the end user. The application layer is responsible for end-user verification. The S3 administrator must assign S3 credentials for the application or set of applications and optionally, map those S3 credentials to a data-fabric identity.

As defined in the [Amazon S3 documentation](#), the S3 REST API uses a “key” and “secret” (in a REST-like manner) as credentials to authenticate to the underlying object storage and authorize access to data.

S3 gateway supports a multi-tenant scenario in which the S3 administrator can configure one or more credentials with the appropriate data-fabric credential mapping. The S3 administrator can assign credentials to a user and, optionally, map them to a data-fabric identity.

For an overview of tenants and multi-tenancy, see [Multitenancy on File System](#) on page 450.

### Adding Credentials and Policies

You add credentials and policies from the MinIO Client (mc), which is located here: `/opt/mapr/objectstore-client/objectstore-client-<version>/util/mc`. For examples of using the MinIO Client, see the [MinIO Admin Complete Guide](#).

The only difference is that in the S3 gateway, you can additionally specify the UID and GID for the user to ensure that FS mode is working. For example:

```
mc admin user add SERVER_ALIAS USERNAME PASSWORD UID GID
```

### Restarting the S3 Gateway Service

Start, restart, or stop the S3 gateway by using the command appropriate for the node:

#### Server Node

```
/opt/mapr/bin/maprcli node services -name objectstore -nodes
<node_name> -action [start |
 restart | stop]
```

#### Edge Node

```
sudo /opt/mapr/objectstore-client/objectstore-client-<version>/bin/
objectstore.sh [start |
 stop]
```

### Configuring the S3 Gateway Client

Describes how to configure the client and provides client configuration and operation examples.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

EEP 7.1.0 and later supports S3 gateway 2.1.0 and higher. S3 gateway 2.2.0.0 is available starting in EEP 8.0.0.

The S3 gateway (MinIO) client is located in `/opt/mapr/objectstore-client/objectstore-client-<version>/util/mc`.

Before you complete the tasks described in the following sections, complete the tasks in [Configuring S3 Gateway](#) on page 4188 to configure S3 gateway.

### Add an S3-Compatible Service

To add an S3-compatible service, run the `mc alias set` command, as shown:

```
mc alias set ALIAS HOSTNAME ADMIN_ACCESS_KEY ADMIN_SECRET_KEY
```

#### Example

```
mc alias set myminio http://localhost:9000 minioadmin minioadmin
```

### Create a User

You can create a user with or without a UID and GID. When you create a user without a UID and GID, the UID and GID for the S3 gateway process is used.

- **Creating a user without the UID and GID**

Run the `mc admin user add` command, as shown:

```
mc admin user add ALIAS USERNAME PASSWORD
```

Example

```
mc admin user add myminio test qwerty78
```

- **Creating a user with the UID and GID**

Run the `mc admin user add` command with the UID and GID, as shown:

```
mc admin user add ALIAS/ USERNAME PASSWORD UID GID
```

Example

```
mc admin user add myminio test qwerty78 1000 1000
```

For more information, see [MinIO Admin Complete Guide](#).

## Examples

After you configure the client, you can perform bucket and object operations in S3 through Java, Python, Hadoop, and Spark.

This section provides examples with built-in users. In the examples, the default admin user, `minioadmin`, is used.

The examples demonstrate how to perform the following tasks:

- list buckets
- create a bucket
- delete a bucket
- check that a bucket exists
- list files
- upload a file
- delete a file
- check that a file exists

### Java Example

See [Java Examples](#) on page 4195.

### Python Example

See [Python Examples](#) on page 4199.

### Hadoop Example

For Hadoop, provide the `accessKey`, `secretKey`, `host`, and `port`, as shown:

```
-Dfs.s3a.access.key=ACCESS_KEY -Dfs.s3a.secret.key=PASSWORD -Dfs.s3a.endpoint=http(s)://HOST:PORT -Dfs.s3a.path.style.access=true -Dfs.s3a.impl=org.apache.hadoop.fs.s3a.S3AFileSystem
```

## Spark Example

Since Spark uses Hadoop libraries to work with S3, you must provide the accessKey, secretKey, host, and port, as shown:

```
--conf
spark.hadoop.fs.s3a.access.key=ACCESS_
KEY --conf
spark.hadoop.fs.s3a.secret.key=PASSWOR
D --conf
spark.hadoop.fs.s3a.endpoint=http(s):/
/HOST:PORT --conf
spark.hadoop.fs.s3a.path.style.access=
true --conf
spark.hadoop.fs.s3a.impl=org.apache.ha
doop.fs.s3a.S3AFileSystem
```

## Java Examples

Provides examples that show you how to connect to an S3 storage service and perform bucket and object operations in Java.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

The examples provided show the code for connecting and the following operations:

- list buckets
- create a bucket
- delete a bucket
- verify that a bucket exists
- list files
- upload a file
- delete a file
- verify that a file exists

The examples have the following dependency:

```
com.amazonaws:aws-java-sdk-s3:1.11.754
```

## Connection

```
package org.example.objectstore;

import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.services.s3.AmazonS3;

public class Objectstore {
 private static final String USERNAME = "minioadmin";
 private static final String PASSWORD = "minioadmin";
 private static final String URL = "http://localhost:9000";
 private static final String BUCKET_NAME = "test";
 private static final String FILE_NAME = "file";
```

```

 public static void main(String[] args) {
 AWSCredentials credentials = new BasicAWSCredentials(USERNAME,
PASSWORD);
 AmazonS3 s3 = Operations.getConnection(URL, credentials, true);

 Operations.demo(s3, BUCKET_NAME, FILE_NAME);
 }
}

```

## Operations

```

package org.example.objectstore;

 return True

```

### Integrating S3 Gateway with LDAP/AD

Describes how to configure LDAP/AD for S3 gateway 2.1.0 and later.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

The S3 gateway integration uses MinIO LDAP STS to generate temporary credentials when working with an S3 endpoint through a client with a sessionToken. For complete details, see [AssumeRoleWithLDAPIdentity](#).

**Note:** LDAP/AD integration with S3 gateway 2.1.0 and later does not work with Hadoop and Spark because the HPE Ezmeral Data Fabric implementation of Hadoop and Spark does not support sessionToken.

### Configuring the LDAP/AD Integration for S3 gateway

The following LDAP/AD configuration is based on an example test environment:

```
"ldap": {
 "serverAddr": "localhost:389",
 "usernameFormat": "cn=%s,dc=mapr,dc=local",
 "userDNSearchBaseDN": "",
 "userDNSearchFilter": "(cn=%s)",
 "groupSearchFilter": "(&(objectclass=group)(member=%s))",
 "groupSearchBaseDn": "dc=mapr,dc=local",
 "lookUpBindDN": "",
 "lookUpBindPassword": "",
 "stsExpiry": "60h",
 "tlsSkipVerify": "on",
 "serverStartTls": "",
 "serverInsecure": "on"
}
```

Once you have configured LDAP/AD, apply the policy to users/groups, as shown:

```
mc admin policy set myminio readwrite user="cn=admin,dc=mapr,dc=local"
```

### CLI Example

Make a POST request to get credentials. In the request, replace special symbols in the password with the %HEX\_VALUE of your [ASCII](#) symbol. For example, the password abc@123 translates to abc%40123.

The following example shows the POST request using the converted password:

```
curl -X POST "http://127.0.0.1:9000?
Action=AssumeRoleWithLDAPIdentity&LDAPUsername=admin&LDAPPassword=abc%40123&
Version=2011-06-15" | xmllint --format -
```

The request returns a response similar to the following example response:

```
<?xml version="1.0" encoding="UTF-8"?>
<AssumeRoleWithLDAPIdentityResponse xmlns="https://sts.amazonaws.com/doc/
2011-06-15/">
 <AssumeRoleWithLDAPIdentityResult>
 <Credentials>
 <AccessKeyId>N71HK1WE34R2D7F9FDVP</AccessKeyId>
 <SecretAccessKey>NmrkNOXA696CrblWU+eUn0NBwUv+4oUs2u8noJAA</SecretAccessKey>
 <UID/>
 <GID/>
 <Expiration>2021-04-02T23:24:59Z</Expiration>
 <SessionToken>eyJhbGciOiJIUzUxMiIsInR5cCI6IkpXVCJ9.eyJhbnNlc3NLZXkiOiJONzFIS
zFXRTM0UjJEN0Y5RkRWUCIsImV4cCI6MTYxNzQwNTg5OSwibGRhcFVzZXIiOiJjbj1hZGlpbixkY
zltYXByLGRjPWxvY2FsIn0.KY0i3DyOM- IKXi_BHADxZksC8x2PDqjDNBQVIFG-uxBKjJdHrRCnw
XUy0GSGX4Q_XXvhAO4aKj5IIauDc_UceQ</SessionToken>
 </Credentials>
 </AssumeRoleWithLDAPIdentityResult>
 <ResponseMetadata>
 <RequestId>167169A551AF88C8</RequestId>
 </ResponseMetadata>
</AssumeRoleWithLDAPIdentityResponse>
```

## Java LDAP/AD Integration Example

Demonstrates how to integrate LDAP/AD with S3 gateway version 2.1.0 and higher in Java.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

This example has the following dependencies:

- `com.amazonaws:aws-java-sdk-s3:1.11.754`
- `com.squareup.okhttp3:okhttp:4.2.2`
- `com.fasterxml.jackson.dataformat:jackson-dataformat-xml:2.8.5`

```

package org.example.objectstore;

import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicSessionCredentials;
import com.amazonaws.services.s3.AmazonS3;
import com.fasterxml.jackson.databind.JsonNode;
import com.fasterxml.jackson.dataformat.xml.XmlMapper;
import okhttp3.FormBody;
import okhttp3.OkHttpClient;
import okhttp3.Request;
import okhttp3.Response;

import java.io.IOException;

public class ObjectstoreLdap {
 private static final String USERNAME = "admin";
 private static final String PASSWORD = "abc@123";

 private static final String BUCKET_NAME = "test";
 private static final String FILE_NAME = "file";

 public static void main(String[] args) throws IOException {
 String passwordWithoutSpecialCharacters =
replaceSpecialCharacters(PASSWORD);
 System.out.println("Your password without special characters: " +
passwordWithoutSpecialCharacters);

 AWSCredentials credentials = getTemporaryCredentials(URL, USERNAME,
passwordWithoutSpecialCharacters);
 AmazonS3 s3 = Operations.getConnection(URL, credentials, true);

 Operations.demo(s3, BUCKET_NAME, FILE_NAME);
 }

 private static String replaceSpecialCharacters(String string) {
 StringBuilder result = new StringBuilder();
 for (char val : string.toCharArray()) {
 if ((val >= 'a' && val <= 'z') || (val >= 'A' && val <= 'Z') || (val
>= '0' && val <= '9'))
 result.append(val);
 else
 result.append("%").append(Integer.toHexString(val));
 }

 return result.toString();
 }
}

```

```

private static BasicSessionCredentials getTemporaryCredentials(String
url, String username, String password)
throws IOException {
 String requestUrl = new StringBuilder()
 .append(url)
 .append("?Action=AssumeRoleWithLDAPIdentity")
 .append("&LDAPUsername=")
 .append(username)
 .append("&LDAPPassword=")
 .append(password)
 .append("&Version=2011-06-15")
 .toString();

 System.out.println("POST to " + requestUrl);

 Request request = new Request.Builder()
 .url(requestUrl)
 .addHeader("User-Agent", "OkHttp Bot")
 .post(new FormBody.Builder().build())
 .build();

 OkHttpClient httpClient = new OkHttpClient();
 byte[] result;
 try (Response response = httpClient.newCall(request).execute()) {

 if (!response.isSuccessful()) throw new IOException("Unexpected code
" + response);

 result = response.body().bytes();
 }

 return parseCredentials(result);
}

private static BasicSessionCredentials parseCredentials(byte[] response)
throws IOException {
 XmlMapper mapper = new XmlMapper();

 JsonNode node = mapper.readTree(response);
 node =
node.findValue("AssumeRoleWithLDAPIdentityResult").findValue("Credentials");

 String accessKey = node.findValue("AccessKeyId").asText();
 String secretKey = node.findValue("SecretAccessKey").asText();
 String sessionId = node.findValue("SessionToken").asText();

 System.out.println();
 System.out.println("accessKey: " + accessKey);
 System.out.println("secretKey: " + secretKey);
 System.out.println("sessionToken: " + sessionId);

 return new BasicSessionCredentials(accessKey, secretKey, sessionId);
}
}

```

### Python LDAP/AD Integration S3 gateway

Demonstrates how to integrate LDAP/AD with S3 gateway version 2.1.0 and higher in Python.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

This example has the following dependencies:

- boto3 1.15.13
- botocore 1.16.26
- requests 2.24.0
- xmlltodict 0.12.0
- urllib3 1.24.3

```

import json

import boto3
import requests
import urllib3
import xmlltodict
from botocore.client import Config

from operations import *

def get_credentials(host, username, password):
 url = host + "?Action=AssumeRoleWithLDAPIdentity" \
 "&LDAPUsername=" + username + \
 "&LDAPPassword=" + password + "&Version=2011-06-15"
 print("POST to " + url)
 response = requests.post(url)
 data = response.text
 data = xmlltodict.parse(data)
 data = json.dumps(data)
 data = json.loads(data)
 credentials = data["AssumeRoleWithLDAPIdentityResponse"]
["AssumeRoleWithLDAPIdentityResult"]["Credentials"]
 access = credentials["AccessKeyId"]
 secret = credentials["SecretAccessKey"]
 session = credentials["SessionToken"]
 return access, secret, session

def replace_special_characters(string):
 alphanumeric = ""
 for character in string:
 if character.isalnum():
 alphanumeric += character
 else:
 alphanumeric += "%" + str(format(ord(character), "x"))

 return alphanumeric

if __name__ == '__main__':
 host = "http://localhost:9000"
 username = "admin"
 password = "abc@123"
 bucketName = "test"
 file = "file"

 passwordWithoutSpecialCharacters = replace_special_characters(password)
 print("Your password without special characters: " +
passwordWithoutSpecialCharacters)

 accessKey, secretKey, sessionToken = get_credentials(host, username,

```

```
passwordWithoutSpecialCharacters)
print("\n")
print("accessKey: " + accessKey)
print("secretKey: " + secretKey)
print("sessionToken: " + sessionToken)

urllib3.disable_warnings(urllib3.exceptions.InsecureRequestWarning)
s3 = boto3.client('s3',
 endpoint_url=host,
 aws_access_key_id=accessKey,
 aws_secret_access_key=secretKey,
 aws_session_token=sessionToken,
 config=Config(signature_version='s3v4'),
 region_name='us-east-1',
 verify=False)

demo(s3, bucketName, file)
```

### Using the HPE Ezmeral Data Fabric Event Streams for S3 Bucket Event Notifications

You can use the HPE Ezmeral Data Fabric Event Streams to receive event notifications for buckets. For example, when an object is created in a bucket. Install the event store, create a stream and topic, and then enable notifications through the MinIO client (MC) located in `/opt/mapr/objectstore-client/objectstore-client-<version>/util/mc`.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

### Enabling Bucket Notification

**Note:** S3 gateway 2.1.0 and later does not support integration with HPE Ezmeral Data Fabric Event Streams. The configuration is specifically for S3 gateway 2.0.x only.

To enable bucket-notification functionality, complete the following steps:

1. Install the `mapr-kafka*` package:

```
zypper|yum|apt-get install mapr-kafka
```

2. Create a stream and topic:

```
maprcli stream create -path /path/to/stream
maprcli stream topic create -path /path/to/stream -topic nameOfTopic
```

3. Add a new channel by using MC:

```
mc admin config set myminio notify_kafka:1 queue_dir=""
queue_limit="0" topic="/path/to/stream:nameOfTopic"
```

4. Restart the S3 gateway.

Now you can add events for notifications. For more information, see step 3 in this [MinIO article](#).

### Reading a Topic

To read a topic:

```
/opt/mapr//kafka/kafka-<version>/bin/kafka-console-consumer.sh --topic
/path/to/stream:nameOfTopic --bootstrap-server some:9092 --from-beginning
```

## AWS CLI

You can install and use the AWS Command Line Interface (CLI) with the S3 gateway.

### Installing the AWS CLI

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

To install the AWS CLI on Ubuntu, RedHat/CentOS, or SLES, run:

```
pip install awscli
```

To configure the AWS CLI, use the `AWS configure` command with the values shown in the following table:

| Value                 | Description                                    |
|-----------------------|------------------------------------------------|
| AWS Access Key ID     | Insert the <code>accessKey</code> for the user |
| AWS Secret Access Key | Insert the <code>secretKey</code> for the user |
| Default region name   | Specify 'us-west-1'                            |
| Default output format | Specify <code>json</code>                      |

### Using the AWS CLI

The following table provides examples of commands that can help you manage buckets and files.

**Note:** The `public.crt` file is the public certificate for the node that is generated by Data Fabric.

```
Create a bucket and upload a file
aws s3 mb s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

echo "HelloS3World" > /tmp/helloS3world.txt
aws s3 cp /tmp/helloS3world.txt s3://mybucket/
helloS3world.txt --endpoint-url https://<ip-address>:9000 --ca-bundle /
absolute/path/to/public.crt

Move an object from one bucket to another
aws s3 mv s3://firstbucket/helloS3world.txt s3://mybucket/
helloS3world.txt --endpoint-url https://<ip-address>:9000 --ca-bundle /
absolute/path/to/public.crt

Delete an object from a bucket
aws s3 rm s3://mybucket/helloS3world.txt --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

Delete the bucket
aws s3 rb s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

List all files in the bucket

aws s3 ls s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

Show all files on the filesystem
ls -al /mapr/demo.mapr.com/apps/s3/$(hostname)/mybucket/
```

## AWS CLI Limitations

If you list a folder in FS deployment mode and at least one of the files or buckets has permissions that deny access, an access-deny error is returned.

### Related concepts

[Understanding the Key Store and Trust Store Files](#) on page 1524

Provides a comprehensive listing of the key store and trust store files.

### Related reference

[configure.sh](#) on page 2331

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

## Logs for the S3 Gateway

Logs for the S3 Gateway are available after the first run. You can access logs in `/opt/mapr/objectstore-client/objectstore-client-<version>/logs/`.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

The `minio.log` is rotated daily. Logs from previous days are archived to `minio.log-<date>.gz`.

To change the level of detail (verbosity) displayed in `minio.log`, you can edit the `logLevel` field in the `minio.json` file:

```
/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json
```

Specify a number (1 through 6) to set the log verbosity level:

```
1 - Panic (less detail)
2 - Fatal
3 - Error
4 - Warning
5 - Info
6 - Debug (more detail)
```

## S3 Gateway Limitations

The S3 Gateway has certain limitations and restrictions involving protocol support, object naming, and specific object and bucket APIs that are not supported.

**Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

### POSIX limitations

Because the S3 gateway uses POSIX to access the data-fabric filesystem, any POSIX limitations are applicable to the S3 gateway.

### FUSE-Based POSIX client limitations

If work with data is planned on different nodes, pay attention to the value (0 or 1) of the `fuse.disable.writeback` property. If caching is enabled (0), it can cause an issue with the FUSE clients. For example, if multiple FUSE clients work on the same file, writes to a file by one FUSE client might never be seen by other FUSE clients performing a read because the kernel does not update the attributes of the file unless the file is modified locally. For more information, see [Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client](#) on page 1358.

**S3 gateway instance limitations**

- In S3 gateway 2.0.0, for multiple instances of S3 gateway to use the same mount folder, only one instance of S3 gateway can run as the main instance; all other instances of S3 gateway must be in stand-by mode. This facilitates the simplest realization of High Availability (HA) without distributed mode.

**Object name character restrictions**

You cannot use object names that contain characters `^\*|` are NOT supported in Windows and other file systems which do not support them.

**S3 object APIs not supported**

- ObjectACL (Use bucket policies instead)
- ObjectTorrent
- ObjectVersions

**S3 Bucket APIs not supported**

- BucketACL (Use bucket policies instead)
- BucketCORS (CORS enabled by default on all buckets for all HTTP verbs)
- BucketLifecycle (Not required for Minio erasure coded backend)
- BucketReplication (Use mc mirror instead)
- BucketVersions, BucketVersioning (Use s3git)
- BucketWebsite (Use caddy or nginx)
- BucketAnalytics, BucketMetrics, BucketLogging (Use bucket notification APIs)
- BucketRequestPayment
- BucketTagging

**File deletion limitation**

If you delete a file using S3 gateway, it will delete the metadata file but not the metadata directory of the file.

**Oozie**

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Apache Oozie™ is a workflow scheduler system to manage Apache Hadoop jobs. Using Oozie, you can set up *workflows* that execute MapReduce applications and *coordinators* that manage workflows.

Oozie Workflow jobs are Directed Acyclical Graphs (DAGs) of actions. Oozie Coordinator jobs are recurrent Oozie Workflow jobs triggered by time (frequency) and data availability.

Oozie is integrated with the rest of the Hadoop stack and supports several types of Hadoop jobs out-of-the-box, such as Java map-reduce, Streaming map-reduce, Pig, Hive, Sqoop, and Distcp, as well as system-specific jobs, such as Java programs and shell scripts.

This section contains documentation for Oozie on the MapR Data Platform and provides all relevant details needed to use Oozie. The documentation in this section does not duplicate the documentation on the [Apache Oozie site](#).

### Configure Oozie

This topic describes how to configure Oozie.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

To set up Oozie using a non-default administrative user (non-mapr), set the `yarn.resourcemanager.principal` property to the non-mapr user in the `yarn-site.xml` file. For more information, see [yarn-site.xml](#).

In Oozie 4.3.0, when you modify the `yarn-site.xml` file on Oozie server nodes, you must rebuild the Oozie war file to include the latest changes using one of the following two methods:

#### 1. First method:

##### a. Rebuild the Oozie war files:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh hadoop
<version> /opt/mapr/hadoop/hadoop<version> -secure
```

##### b. Restart Oozie:

```
maprcli node services -name oozie -action restart -nodes <space
delimited list of nodes>
```

#### 2. Second method:

- Or, for EEP 4.x and Oozie 5.1 (EEP 6.x), you can run the following command:

```
/opt/mapr/server/configure.sh -R
```

### Configuring Oozie on a Secure Cluster

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The default configuration for Oozie on a secure cluster uses [MapR tickets](#) to authenticate between the Oozie client and server. The Oozie server uses tickets to authenticate the connection between the YARN components and the JobClient embedded in the Oozie server. Starting in the EEP 4.0 release, for secure clusters, Oozie is also configured to use SSL encryption. This default configuration is in place once Oozie is installed and the security features for your cluster are enabled. See [Enabling and Disabling Security](#). No further configuration is required. See [User Impersonation for Oozie](#) to enable user impersonation for Oozie.

The sections below provide instructions to manually configure Oozie features on a secure cluster:

#### Oozie Server secured by default to use SSL

Starting in EEP 6.0.0, for Oozie 4.3.0 and above, Oozie server uses SSL by default for secured clusters.

1. By default, on a secure cluster, Oozie reads the `ssl-client.xml` file and configures SSL using this file.
2. If you want to use a custom SSL configuration, enable [custom secure](#) on your cluster.

### Configuring the Oozie Server to use SSL (Oozie 5.1.0.0 and above)

Configure the settings necessary for enabling SSL or TLS support in the `oozie-site.xml` file.

1. Set the `oozie.https.enabled` property to `true`:

```
<property>
 <name>oozie.https.enabled</name>
 <value>>true</value>
 <description>Controls whether SSL encryption is enabled.</description>
</property>

<property>
 <name>oozie.https.truststore.file</name>
 <value>/opt/mapr/conf/ssl_truststore</value>
 <description>Path to a TrustStore file.</description>
</property>

<property>
 <name>oozie.https.keystore.file</name>
 <value>/opt/mapr/conf/ssl_keystore</value>
 <description>Path to a KeyStore file.</description>
</property>

<property>
 <name>oozie.https.keystore.pass</name>
 <value><password></value>
 <description>Password to the KeyStore.</description>
</property>
```

**Note:** To configure the Oozie for `http`, set the `oozie.https.enabled` property to `false`.

2. Connect to the Oozie Web UI using SSL (HTTPS):

```
https://oozie.server.hostname:11443/oozie
```

You can also encrypt the [Oozie keystore password](#). For more information, refer to the [open source documentation](#).

### Configuring Oozie Clients to Use SSL (Oozie 4.3.0)

To configure the Oozie clients, follow this step:

- Specify the path to the keystore and password at `/opt/mapr/oozie/oozie-<version>/conf/oozie-client-env.sh`:

```
export
OOZIE_CLIENT_OPTS="{OOZIE_CLIENT_OPTS} -Djavax.net.ssl.trustStore=/opt/
mapr/conf/ssl_truststore"
```

### Using Kerberos to Securely Authenticate Between the Oozie Client and Server

Oozie can use Kerberos to secure authentication between the Oozie client and server. The Oozie server uses the Kerberos principal and keytab information specified in the Java Authentication and Authorization (JAAS) configuration file at `/opt/mapr/conf/mapr.login.conf`. Generate a Kerberos principal of the form `http/<fqdn>@<realm>` and store the keytab in the cluster's keytab file. The default keytab file location is `/opt/mapr/conf/mapr.keytab`.

To use Kerberos authentication on a specific invocation of Oozie without modifying your client, use the `-auth KERBEROS` option when you start Oozie, as in the following example:

```
$ bin/oozie admin -status -auth KERBEROS
```

### Defining a Custom Principal and Keytab File

You can use custom Kerberos principals and keytab files if you wish. To specify the locations of these custom Kerberos principals and keytab files, make the following modifications to the `oozie-site.xml` file:

- Explicitly change the authentication type to Kerberos.

```
<property>
 <name>oozie.authentication.type</name>
 <value>kerberos</value>
 <description>
 Defines authentication used for Oozie HTTP endpoint.
 Supported values are: simple | kerberos |
 #AUTHENTICATION_HANDLER_CLASSNAME#
 </description>
</property>
```

- Modify the following entries to use your custom principals and keytab. The principal takes the form `HTTP/<hostname>`, where *hostname* is the URL used by the client to connect to the server.

```

<property>
 <name>oozie.service.HadoopAccessorService.keytab.file</name>
 <value>/opt/mapr/conf/mapr.keytab</value>
 <description>
 Location of the Oozie user keytab file.
 </description>
</property>

<property>
 <name>local.realm</name>
 <value>{local.realm}</value>
 <description>
 Kerberos Realm used by Oozie and Hadoop. Using 'local.realm' aligns
 with Hadoop configuration
 </description>
</property>

<property>
 <name>oozie.service.HadoopAccessorService.kerberos.principal</name>
 <value>mapr/<hostname>@${local.realm}</value>
 <description>
 Kerberos principal for Oozie service.
 </description>
</property>

<property>
 <name>oozie.authentication.kerberos.principal</name>
 <value>HTTP/<hostname>@${local.realm}</value>
 <description>
 Indicates the Kerberos principal to be used for the HTTP endpoint.
 The principal MUST start with 'HTTP/' per the Kerberos HTTP SPNEGO
 specification.
 </description>
</property>

```

- Optional: If you plan to run Oozie actions that require talking to external services, add the `oozie.credentials.credentialclasses` to `oozie-site.xml`. For more details, see the [Oozie documentation](#).

```

<property>
 <name>oozie.credentials.credentialclasses</name>
 <value>
 hcat=org.apache.oozie.action.hadoop.HCatCredentials,
 hbase=org.apache.oozie.action.hadoop.HbaseCredentials,
 hive2=org.apache.oozie.action.hadoop.Hive2Credentials
 </value>
</property>

```

**Note:** No specific configuration is required for configuring Oozie to use data-fabric-SASL.

### Disabling Cached Tokens

After a client authenticates to Oozie, the authentication token received by the client is cached in the user's home directory in the `.oozie-auth-token` file. As long as the cached token remains valid, future authentication requests from the same client use that token and succeed, even if the client's Kerberos or

credentials have expired or have been revoked. You can disable use of the cache file by using the `oozie` command-line interface with the `-Doozie.auth.token.cache false` option.

### Configuring Security Headers for Web Servers for Oozie

This section describes how to configure response headers for REST API servers used in the Oozie web UI.

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

#### About the Headers File

The XML file with security headers is located at:

```
/opt/mapr/oozie/oozie-<version>/conf/security-headers.xml
```

The `security-headers.xml` file contains the following headers:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE properties SYSTEM
"http://java.sun.com/dtd/properties.dtd">
<properties>
 <comment>Security headers that is used to minimize the possibility of
cross-site scripting and other attacks</comment>
 <entry key="X-XSS-Protection">1; mode=block</entry>
 <entry key="X-Content-Type-Options">nosniff</entry>
 <entry
key="Strict-Transport-Security">max-age=31536000;includeSubDomains</entry>
 <entry key="Content-Security-Policy">default-src https:</entry>
</properties>
```

This table describes each header:

| Header                    | Description                                                                                                                                                          | Default Value                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| X-XSS-Protection          | Stops pages from loading when reflected cross-site scripting (XSS) is detected. Supported by IE, Chrome, and Safari.                                                 | 1: mode=block                      |
| X-Content-Type-Options    | Indicates that the MIME types advertised in the <code>Content-Type</code> headers should not be changed and should be followed.                                      | nosniff                            |
| Strict-Transport-Security | Tells all browsers that the website should only be accessed using HTTPS instead of using HTTP.                                                                       | max-age=31536000;includeSubDomains |
| Content-Security-Policy   | Allows web-site administrators to control resources the user agent is allowed to load for a given page. This helps guard against cross-site scripting attacks (XSS). | default-src https:                 |

### Configuring Security Headers for Oozie

To enable security headers for Oozie, add the following to the `oozie-site.xml` file, and replace `<version>` with your Oozie version:

```
<property>
<name>oozie.server.response.headers</name>
<value>/opt/mapr/oozie/oozie-<version>/conf/security-headers.xml</value>
</property>
```

## Configuring Custom Headers

To configure custom headers for web servers, edit the `headers.xml` file, and add `Custom-header` as follows:

```
<entry key="Custom-header">custom-value</entry>
```

## Security Headers Auto-Configuration

If you install Oozie on a secure cluster (data-fabric-SASL or Kerberos) and run the following command after Oozie installation, Oozie automatically configures itself to enable security headers, and no additional action is needed:

```
/opt/mapr/server/configure.sh -R
```

## Configure High Availability for Oozie

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

To configure HA for Oozie on your cluster, the cluster must meet the following prerequisites:

- Your cluster must have access to a database with support for multiple concurrent connections. To prevent this database from becoming a single point of failure, the database must support HA. HA for the Oozie service works regardless of the database's HA status. See [MySQL Data Store for Oozie](#).
- To prevent the ZooKeeper service from becoming a single point of failure, your cluster must have at least 3 ZooKeeper nodes. You can still configure HA for Oozie on clusters with a single ZK node.
- Multiple nodes on the cluster must have Oozie installed. For installation instructions, see the [Installing Core and Ecosystem Components](#) on page 87.

**Note:** For greater consistency of behavior on your cluster, verify that all of the Oozie servers have the same configuration.

- A load balancer, virtual IP, or round-robin DNS set up, such as HAProxy. To prevent the load balancer from becoming a single point of failure, the load balancer must support HA.
1. Verify that the Oozie servers are all configured to connect to the same database. Do not start Oozie.
  2. On each Oozie node, edit the `oozie-site.xml` file to add the following section, which changes the results in Oozie using the Zookeeper's version of the services, overriding the default implementations:

```
<property>
 <name>oozie.services.ext</name>
 <value>
 org.apache.oozie.service.ZKLocksService,
 org.apache.oozie.service.ZKXLogStreamingService,
 org.apache.oozie.service.ZKJobsConcurrencyService,
 org.apache.oozie.service.ZKUUIDService
 </value>
</property>
```

- On each Oozie node, edit the `oozie-site.xml` file to include a comma-separated list of the host names and ports for the ZooKeeper servers. For example:

```
<property>
 <name>oozie.zookeeper.connection.string</name>
 <value>zk1:5181,zk2:5181,zk3:5181</value>
</property>
```

- On each Oozie node, edit the `oozie-site.xml` file to include the Oozie server host name:

```
<property>
 <name>oozie.http.hostname</name>
 <value><FQDN></value>
</property>
```

- On each Oozie node, edit the `oozie-site.xml` file to specify the namespace. Each Oozie server that communicates to other Oozie servers must use the same namespace:

```
<property>
 <name>oozie.zookeeper.namespace</name>
 <value>oozie</value>
</property>
```

- On each Oozie node, change the value of the `OOZIE_BASE_URL` property in the `oozie-site.xml` file to point to the load balancer or virtual IP.

```
<property>
 <name>oozie.base.url</name>
 <value>http://my.loadbalancer.hostname:<oozie_port_number>/oozie/</value>
</property>
```

The `<oozie_port_number>` depends on whether your cluster is secure.

- On all nodes, update the services line in the `warden.oozie.conf` file (stored at `/opt/mapr/conf/conf.d`; or for a fresh installation, at `/opt/mapr/oozie/oozie-<version>/conf/warden.oozie.conf`) from:

```
services=oozie:1:cldb
```

to

```
services=oozie:all:cldb
```

- Run the `configure.sh -R` command.
- Run Oozie share lib update command to make sure that all Oozie services use the latest and the same version:

```
{OOZIE_HOME}/bin/oozie admin -oozie="http(s)://
my.loadbalancer.hostname:<oozie_port_number>" -sharelibupdate
```

## Configure a MySQL Data Store for Oozie

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Follow these steps to configure Oozie to use a MySQL database as the Oozie data store (instead of the default Apache Derby database). The MySQL database can also be used to support [high availability \(HA\)](#).

1. Using the `mysql` command-line tool, create a MySQL database, user, and password for the Oozie user. For example:

```
mysql> create database oozie;
mysql> grant all privileges on oozie.* to '<oozie-user>'@'%' identified
by '<oozie-passwd>';
```

2. Stop the Oozie server:

```
maprcli node services -name oozie -action stop -nodes <node-list>
```

3. Set the following JPAService properties in the `oozie-site.xml` file: **Note:** In the JDBC URL property, use the correct hostname (where MySQL is running).

```
<property>
 <name>oozie.service.JPAService.jdbc.driver</name>
 <value>com.mysql.jdbc.Driver</value>
</property>
<property>
 <name>oozie.service.JPAService.jdbc.url</name>
 <value>jdbc:mysql://localhost:3306/oozie</value>
</property>
<property>
 <name>oozie.service.JPAService.jdbc.username</name>
 <value>oozie</value>
</property>
<property>
 <name>oozie.service.JPAService.jdbc.password</name>
 <value>oozie</value>
</property>
```

4. For earlier EEP 4.1.0 versions, copy the MySQL JDBC driver `mysql-connector-java-<version>-bin.jar` file to the following directory.

```
/opt/mapr/oozie/oozie-<oozieversion>/libext
```

For EEP 4.1.0 and later, the JDBC driver file `mysql-connector-java-<version>-bin.jar` is automatically copied from the `/opt/mapr/lib/` directory to the `/opt/mapr/oozie/oozie-<oozieversion>/libext` directory.

See the [repository](#) to confirm default MySQL JDBC driver in `/opt/mapr/oozie/oozie-<oozieversion>/libext` directory is compatible with your MySQL or MariaDB version. Download and update the default JDBC driver file with the driver file that is compatible with your MySQL or Maria DB version.

5. Start the Oozie server:

```
maprcli node services -name oozie -action start -nodes <node-list>
```

6. Check that MySQL is now in use by looking at the contents of the `oozie.log` file. For example:

```
cat /opt/mapr/oozie/oozie-<version>/logs/oozie.log |grep mysql
2015-07-24 06:10:07,023 INFO JPAService:541 - SERVER[local.novalocal]
USER[-]
GROUP[-] TOKEN[-] APP[-] JOB[-] ACTION[-] JPA configuration:
DriverClassName=com.mysql.jdbc.Driver,Url=jdbc:mysql://localhost:3306/
oozie,Username=oozie,...
```

7. To encrypt the Oozie database user password, see [Encrypt the Oozie Database User Password](#) on page 4218.

#### *Configuring an Oracle Schema*

You must create schemas for Oracle databases manually.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Create an Oozie SQL-with-schema file to reveal the schema:

```
bin/ooziedb.sh create -sqlfile oozie.sql -run
```

For more information, see the [Apache Oozie documentation](#).

#### **Encrypt the Oozie Database User Password**

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Follow these steps to encrypt the password when Oozie uses a MySQL database as the Oozie data store (instead of the default Apache Derby database).

1. Configure Oozie to use a MySQL database as described in [Configure a MySQL Data Store for Oozie](#) on page 4217.
2. [OPTIONAL] Export the Hadoop credential store password as a system variable:

```
$ export HADOOP_CREDSTORE_PASSWORD=password
```

3. Add `oozie.service.jpaservice.jdbc.password` to the jceks keystore:

```
$ hadoop credential create
oozie.service.jpaservice.jdbc.password -provider jceks://path/to/
oozie.jceks
Enter the password:
Enter the password again:
oozie.service.jpaservice.jdbc.password has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

#### 4. Verify that the MySQL password was added:

```
Keystore type: JCEKS
Keystore provider: SunJCE

Your keystore contains 1 entry

Alias name: oozie.service.jpaservice.jdbc.password
Creation date: Apr 11, 2018
Entry type: SecretKeyEntry
```

#### 5. Once the jceks file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file with the path to the jceks file. The jceks path location can be `maprfs` or a local file (`local-fs`).

```
<property>
 <name>hadoop.security.credential.provider.path</name>
 <value>jceks://path/to/oozie.jceks</value>
</property>
```

#### 6. Update the password property to use `*****` instead of a word-readable password:

```
<property>
 <name>oozie.service.JPAService.jdbc.password</name>
 <value>*****</value>
</property>
```

### Encrypt the Oozie Keystore Password

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Starting from Oozie 5.1.0.0, follow these steps to encrypt the keystore password when Oozie is [configured to use SSL](#).

 **Note:** Oozie 5.1.0.0 is configured to use SSL by default on secure clusters.

#### 1. [OPTIONAL] Export the Hadoop credential store password as a system variable:

```
$ export HADOOP_CREDSTORE_PASSWORD=password
```

#### 2. Add `oozie.https.keystore.pass` to the jceks keystore:

```
$ hadoop credential create oozie.https.keystore.pass -provider jceks://
path/to/oozie.jceks
Enter the password:
Enter the password again:
oozie.https.keystore.pass has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

- Once the `jceks` file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file along with the path to the `jceks` file. The `jceks` path location can be `maprfs` or a local file (`local-fs`).

```
<property>
 <name>hadoop.security.credential.provider.path</name>
 <value>jceks://path/to/oozie.jceks</value>
</property>
```

- Update the `password` property to use `*****` instead of a word-readable password:

```
<property>
 <name>oozie.https.keystore.pass</name>
 <value>*****</value>
</property>
```

**Note:** You can use the same `jceks` file for storing both database and keystore passwords.

### User Impersonation for Oozie

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Oozie supports *impersonation*, which enables Oozie to run jobs as a user other than the user that started the Oozie server. You can set up proxy user functionality if you want Oozie to impersonate a user from a set of hosts, or to impersonate a user that belongs to a set of groups. When you configure proxy user functionality, the proxy user can perform “doAs” operations. Add configuration properties to the `oozie-site.xml` and `core-site.xml` files to configure proxy user functionality.

Add the following configuration properties to the `oozie-site.xml` file:

- `oozie.service.ProxyUserService.proxyuser.#USER#.hosts`
- `oozie.service.ProxyUserService.proxyuser.#USER#.groups`

Replace `#USER#` with the username of the proxy that can perform “doAs” operations. For the host property, you can add a list of host names as the value. For the group property, you can add a list of groups as the value. Alternatively, you can add a wildcard character (\*) as the value for host and group properties. To add multiple users, copy the property and replace `#USER#` with the proxy user name.

### Host Example

```
<property>
 <name>oozie.service.ProxyUserService.proxyuser.mapr.hosts</name>
 <value>*</value>
</property>
```

### Group Example

```
<property>
 <name>oozie.service.ProxyUserService.proxyuser.mapr.groups</name>
 <value>*</value>
</property>
```

Add the following configuration properties to the `core-site.xml`:

- `hadoop.proxyuser.#USER#.hosts`
- `hadoop.proxyuser.#USER#.groups`

Replace #USER# with the username of the proxy.

When you add the host property, the proxy user can only connect from a host to impersonate a user. When you add the group property, the proxy user can impersonate any member of any group.

### Host Example

```
<property>
 <name>hadoop.proxyuser.mapr.hosts</name>
 <value>*</value>
</property>
```

### Group Example

```
<property>
 <name>hadoop.proxyuser.mapr.groups</name>
 <value>*</value>
</property>
```

### Updating the Oozie Shared Libraries

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

You must update the Oozie shared libraries when:

- the `oozie.service.WorkflowAppService.system.libpath` property in the `oozie-site.xml` file is changed from the default value (`/oozie/share/lib`).
- a core patch is installed.

By default, the Oozie shared libraries are uploaded to the `maprfs:///oozie/share/lib` directory.

To update the Oozie shared libraries, complete the following steps:

1. Run the following command to copy the new Oozie shared libraries to the filesystem:

```
{OOZIE_HOME}/bin/oozie-setup.sh sharelib create -fs
maprfs:/// -locallib /opt/mapr/oozie/oozie-<version>/share
```

2. Run the following command to update the Oozie classpath with the new shared libraries:

```
{OOZIE_HOME}/bin/oozie admin -sharelibupdate -oozie https://<FQDN>:11443/
oozie
```

### Use Oozie

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The following sections provide information about using Oozie:

#### Manage Oozie Services and Interface

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

You can manage Oozie services and the Oozie interface through the command line or Oozie Web UI.

The following sections provide information about managing Oozie:

*Starting, Stopping, and Restarting Oozie Services*

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The Warden daemon starts the Oozie server automatically at installation time. You can start and stop Oozie from the command line or from the Control System. Using the `maprcli node services` command enables you to start Oozie on multiple nodes at one time.

**Starting, Stopping, and Restarting Oozie using maprcli**

Complete the following steps to start | stop | restart Oozie from the command line:

1. Make a list of nodes on which Oozie is configured.
2. Issue the `maprcli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which Oozie is configured, separated by spaces.

**Example:**

```
maprcli node services -name oozie -action start|stop|restart -nodes
<nodes list>
```

*Enabling the Oozie Web UI*

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The Oozie web UI can display your job status, logs, and other related information. You must enable the Oozie Web UI after you install Oozie. However, depending on how you enable the Web UI, you may also need to perform manual steps to start the Web UI after you run `configure.sh` on the cluster.

1. Download the Ext JS 2.2 library as a zip archive (`ext-2.2.zip`). You can download this library from the [Apache Oozie Quick Start guide](#). Search for "ExtJS 2.2" on the page to find the link.

**Note:** The Ext JS 2.2 library is required only for the Oozie Web UI. A [rewrite of the Oozie web UI](#) has been proposed in the Oozie user community.

2. Copy the Ext JS 2.2 library into the `libext` directory:

```
cp ext-2.2.zip /opt/mapr/oozie/oozie-<version>/libext/
```

3. **Applicable only for Oozie 4.X versions:** Perform one of the following options based on your preference:

- If you want the Oozie Web UI to start whenever Oozie starts or restarts, perform the following steps:
  - a. If Oozie is running, shut it down:

```
maprcli node services -name oozie -action stop -nodes <space
delimited list of nodes>
```

- b. Run the `oozie-setup.sh` script, and specify the hadoop version.

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh -hadoop
<version> /opt/mapr/hadoop/hadoop-<version>
```

**Note:** If you are enabling the Oozie Web UI on a secure cluster and SSL must be configured, run the command with the `-secure` option:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh -hadoop
<version> /opt/mapr/hadoop/hadoop-<version> -secure
```

- If you want to manually start the Web UI when Oozie starts or restarts, perform the following steps:
  - a. If Oozie is running, shut it down:

```
maprcli node services -name oozie -action stop -nodes <space
delimited list of nodes>
```

- b. Run the `oozie-setup.sh` script and specify the path to the `extjs` file.

```
cd /opt/mapr/oozie/oozie-<version>
bin/oozie-setup.sh prepare-war -extjs ~/ext-2.2.zip
```

#### 4. Restart Oozie.

```
maprcli node services -name oozie -action restart -nodes <space
delimited list of nodes>
```

#### Checking the Status of Oozie

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Once Oozie is installed, you can check the status using the command line or the Oozie web console. The `<oozie_port_number>` noted in the URLs depend on whether your cluster is secure.

#### Check Status from Command Line

Use the `oozie admin` command:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie admin -oozie http(s)://
<oozie_node>:<oozie_port_number>/oozie -status
```

The following output indicates normal operation:

```
System mode: NORMAL
```

#### Check Status from the Oozie Web Console

Point your browser to `http://<oozie_node>:<oozie_port_number>/oozie`

**Note:**

- For non-secure clusters:

```
Oozie url: http://<oozie_node>:11000/oozie
```

- For secure clusters:

```
Oozie url: https://<oozie_node>:11443/oozie
```

**Setup and Run Oozie Examples**

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

To get familiar with Oozie, set up and try the examples.

1. Complete the following steps to set up the examples and copy them to the cluster:

- a) Extract the oozie examples archive `oozie-examples.tar.gz`:

```
cd /opt/mapr/oozie/oozie-<version>
tar xvfz ./oozie-examples.tar.gz -C /opt/mapr/oozie/oozie-<version>/
```

- b) Copy the examples to filesystem. Run the following command as a user that has permissions to write to the specified filesystem directory:

```
hadoop fs -put examples maprfs:///user/<user_name>/examples
```

2. Complete the following steps to run the examples:

- a) Choose an example and run it with the `oozie job` command. You can use the following commands to run the following examples. The `<oozie_port_number>` depends on whether your cluster is secure.

- MapReduce

```
/opt/mapr/oozie/oozie-<version>/bin/oozie job -oozie="http://localhost:<oozie_port_number>/oozie" -config /opt/mapr/oozie/oozie-<version>/examples/apps/map-reduce/job.properties -run
```

- Spark

```
/opt/mapr/oozie/oozie-<version>/bin/oozie job -oozie="http://localhost:<oozie_port_number>/oozie" -config /opt/mapr/oozie/oozie-<version>/examples/apps/spark/job.properties -run
```

**Note:** To run the packaged Hive examples, make `/tmp` on filesystem world-writable. Set `/tmp` to `777`. Example:

```
hadoop fs -chmod -R 777 /tmp
```

If `/tmp` does not exist, create `/tmp` and then set it to `777`.

## Check the Status of a Job

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

You can check the status of a job from the command line or the Oozie Web Console.

From the command line, issue the following (substituting the job ID for the <job id> placeholder):

```
/opt/mapr/oozie/oozie-<version>/bin/oozie job -info <job id>
```

To check status from the Oozie Web Console, point your browser to `http://<Oozie_node>:<oozie_port_number>/oozie` and click **All Jobs**. The `<oozie_port_number>` depends on whether your cluster is secure.

## Run Hive Jobs with Oozie

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

You run Hive jobs with Oozie by configuring a Hive workflow.

1. **Configure a Hive workflow.** You can configure Oozie to perform a workflow by connecting to Hive Metastore or Hiveserver2.

### Configure a Hive Workflow with Connection to Hive Metastore

- a. To use a metastore server for the Hive job, add the following parameter to the `hive-site.xml` file:

```
<property>
 <name>hive.metastore.uris</name>
 <value>thrift://<IP address>:<port></value>
 <description>IP address (or fully-qualified domain name) and port
of the metastore host</description>
</property>
```

- b. Copy the edited `hive-site.xml` file to the same location as your `workflow.xml` file.
- c. If you are using the Hive-on-Tez engine, and you have changed the default `tez-site.xml` configuration, perform one of the following steps:
  - Copy the `tez-site.xml` file to the same location as your `workflow.xml` file:
    1. Remove the forbidden (forbidden for Oozie) property from `tez-site.xml`:

```
<property>
 <name>fs.defaultFS</name>
 <value>maprfs:///</value>
</property>
```

2. Make sure that you update the value for `tez.lib.uris` property after removing the `fs.defaultFS` property. For example:

```
tez.lib.uris=maprfs:///apps/tez/tez-<version>,maprfs:///apps/tez/
tez-<version>/lib
```

3. Specify the `tez-site.xml` file in the `job-xml` parameter of your workflow.
- Update `<OOZIE_HOME>/conf/action-conf/hive.xml` with the new `tez-site.xml` properties.

- d. Edit the `workflow.xml` file to include the following:
  1. Specify the `hive-site.xml` in the `job-xml` parameter.
  2. Specify the name of the script (for example, `script.q`) that contains the hive query in the `script` parameter.
  3. Optionally, add properties used by the Oozie launcher job. Add the prefix `oozie.launcher` to the property names.

```

<workflow-app xmlns="uri:oozie:workflow:0.2" name="hive-wf">
 <start to="hive-node"/>
 <action name="hive-node">
 <hive xmlns="uri:oozie:hive-action:0.2">
 <job-tracker>${jobTracker}</job-tracker>
 <name-node>${nameNode}</name-node>
 <prepare>
 <delete path="${nameNode}/user/${wf:user()}/${
examplesRoot}/output-data/hive"/>
 <mkdir path="${nameNode}/user/${wf:user()}/${
examplesRoot}/output-data"/>
 </prepare>
 <job-xml>hive-site.xml</job-xml>
 <!-- Add this property if you copied tez-site.xml to the
same location as your workflow.xml file -->
 <job-xml>tez-site.xml</job-xml>
 <configuration>
 <property>
 <name>mapred.job.queue.name</name>
 <value>${queueName}</value>
 </property>
 </configuration>
 <script>script.q</script>
 <param>INPUT=/user/${wf:user()}/${examplesRoot}/
input-data/table</param>
 <param>OUTPUT=/user/${wf:user()}/${examplesRoot}/
output-data/hive</param>
 </hive>
 <ok to="end"/>
 <error to="fail"/>
 </action>

 <kill name="fail">
 <message>Hive failed, error message[${
wf:errorMessage(wf:lastErrorNode())}]</message>
 </kill>
 <end name="end"/>
</workflow-app>

```

### Configure a Hive Workflow with Connection to HiveServer2

- a. Copy the edited `hive-site.xml` file to the same location as your `workflow.xml` file.
- b. On a Kerberos secure cluster for Oozie 4.3.0, perform the following steps:
  1. Copy the `hive-site.xml` file to the `${OOZIE_HOME}/conf/action-conf/` directory.
  2. Rebuild the Oozie war file:

```

/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh
-hadoop <version> /opt/mapr/hadoop/hadoop-<version>

```

- c. Edit the `workflow.xml` file to include the following:
1. Specify the JDBC URL used by Beeline for connections to Hiveserver2 in the `jdbc-url` element. See [Connecting to HiveServer2](#) for details.
  2. Specify the name of the script (for example, `script.q`) that contains the hive query in the `script` element.

```
<?xml version="1.0" encoding="UTF-8"?>
<workflow-app xmlns="uri:oozie:workflow:0.5" name="hive2-wf">
 <start to="hive2-node"/>
 <action name="hive2-node">
 <hive2 xmlns="uri:oozie:hive2-action:0.1">
 <job-tracker>${jobTracker}</job-tracker>
 <name-node>${nameNode}</name-node>
 <prepare>
 <delete path="${nameNode}/user/${wf:user()}/
output-data/hive2"/>
 <mkdir path="${nameNode}/user/${wf:user()}/
output-data"/>
 </prepare>
 <configuration>
 <property>
 <name>mapred.job.queue.name</name>
 <value>${queueName}</value>
 </property>
 </configuration>
 <jdbc-url>jdbc:hive2://localhost:10000/default</
jdbc-url>
 <script>script.q</script>
 <param>INPUT=/user/${wf:user()}/input-data/table</
param>
 <param>OUTPUT=/user/${wf:user()}/output-data/hive2</
param>
 </hive2>
 <ok to="end"/>
 <error to="fail"/>
 </action>
 <kill name="fail">
 <message>Hive2 (Beeline) action failed, error message[
${wf:errorMessage(wf:lastErrorNode())}]</message>
 </kill>
 <end name="end"/>
</workflow-app>
```

## Run Spark Jobs with Oozie

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Complete the following steps to configure Oozie to run Spark jobs:

### Configure a Spark action:

1. For running a Spark action through Oozie, you should be able to connect to Hive on a secure cluster. Make sure the `hive-site.xml` file that is used by Oozie has the following property set:

```
<property>
 <name>hive.metastore.sasl.enabled</name>
 <value>true</value>
</property>
```

2. To add Spark configuration files (`spark-defaults.conf`, `hive-site.xml`, etc) to a Spark action, copy the files to the `{OOZIE_HOME}/share/lib/spark/` directory.
3. If needed, update the Oozie shared libraries as described in [Updating the Oozie Shared Libraries](#) on page 4221.
4. Run pySpark using Spark Action:
  - a. Run pySpark using Spark Action by specifying `pyspark` and `py4j` zip files to the sharelib:
 

```
cp /{SPARK_HOME}/python/lib/ pyspark*.zip {OOZIE_HOME}/share/lib/spark/
cp /{SPARK_HOME}/python/lib/py4j*src.zip {OOZIE_HOME}/share/lib/spark/
```
  - b. Update the Oozie shared libraries as described in [Updating the Oozie Shared Libraries](#) on page 4221.
5. When you configure a Spark action in the `workflow.xml`, specify the `master` and `mode` elements of the Spark job:
  - For Spark standalone mode, specify the Spark Master URL in the `master` element. For example, if your SparkMaster URL is `spark://ubuntu2:7077`, you would replace the `<master> [SPARK MASTER URL]</master>` in the example below with `<master> spark://ubuntu2:7077</master>`.
  - For Spark on YARN mode, specify `yarn-client` or `yarn-cluster` in the `master` element. For example, for `yarn-cluster` mode, you would replace `<master> [SPARK MASTER URL]</master>` with `<master>yarn</master>` and `<mode>[SPARK MODE]</mode>` with `<mode>cluster</mode>`.

Here is an example of a Spark action within a `workflow.xml` file:

```
<workflow-app xmlns='uri:oozie:workflow:0.5' name='SparkFileCopy'>
 <start to='spark-node' />
 <action name='spark-node'>
 <spark xmlns="uri:oozie:spark-action:0.1">
 <job-tracker>${jobTracker}</job-tracker>
 <name-node>${nameNode}</name-node>
 <master>[SPARK MASTER URL]</master>
 <mode>[SPARK MODE]</mode>
 <name>Spark-FileCopy</name>
 <class>org.apache.oozie.example.SparkFileCopy</class>
 <jar>${nameNode}/user/${wf:user()}/${examplesRoot}/apps/spark/lib/oozie-examples.jar</jar>
 <arg>${nameNode}/user/${wf:user()}/${examplesRoot}/input-data/text/data.txt</arg>
 <arg>${nameNode}/user/${wf:user()}/${examplesRoot}/output</arg>
 </spark>
 <ok to="end" />
 <error to="fail" />
 </action>
 <kill name="fail">
 <message>Workflow failed, error
 message[${wf:errorMessage(wf:lastErrorNode())}]
 </message>
 </kill>
</end name='end' />
</workflow-app>
```

### Oozie 5.1.0 API Changes

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Oozie 5.1.0 includes the following changes in the Web Services API. The complete documentation is available at <http://oozie.apache.org/docs/5.1.0/WebServicesAPI.html>

| API                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Get missing dependencies | This endpoint is to show all missing dependencies of coordinator action(s).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Purge Command            | Oozie admin purge command cleans up the Oozie Workflow, Coordinator, or Bundle records based on the specified parameters. The unit for parameters is days. The purge command deletes the workflow records ( <code>wf=30</code> ) older than 30 days, coordinator records ( <code>coord=7</code> ) older than 7 days, and bundle records ( <code>bundle=7</code> ) older than 7 days. The limit ( <code>limit=10</code> ) defines the number of records to be fetched at a given time. Turn on or off ( <code>oldCoordAction true</code> or <code>false</code> ) enables coordinator action record purging for long running coordinators. If any of these parameters are not specified, it is taken from the <code>oozie-default</code> or <code>oozie-site</code> configuration file. |

### Oozie 4.3.0 API Changes

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Oozie 4.3.0 includes the following changes in the Web Services API. Full documentation is available at <http://oozie.apache.org/docs/4.3.0/WebServicesAPI.html>

| API                           | Description                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Validate a local file         | This endpoint is to validate a workflow, coordinator, bundle XML file.                                                  |
| Validate a file in filesystem | You can validate a workflow, coordinator, bundle XML file in filesystem. The XML file must already exist in filesystem. |

### Oozie Known Issues

This topic describes known issues related to Oozie.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

### Spark Oozie Share Library Update Required if Core Patch Applied

If you installed a Core patch for EEP version 6.3.0, 6.3.1, or 7.0.0, the Spark Oozie Share Lib must be updated with the `maprbuildversion` JAR either manually or through an Oozie upgrade.

- When you upgrade to Oozie in EEP 6.3.2, 7.0.1, or later and run `/opt/mapr/server/configure.sh -R`, the `maprbuildversion` JAR is automatically copied from `$MAPR_HOME/lib` to `$OOZIE_HOME/share/lib/spark`.
- Alternatively, you can manually copy the `maprbuildversion` JAR from `$MAPR_HOME/lib` to `$OOZIE_HOME/share/lib/spark` and then run `/opt/mapr/server/configure.sh -R`.

## Oozie Share Library Update Required if Core Patch Applied

After a core patch installation, update the Oozie shared libraries under the `maprfs` directory, as described in [Updating the Oozie Shared Libraries](#) on page 4221.

## Pig

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Apache Pig™ is a platform for analyzing large data sets. Apache Pig™ is a high-level language for expressing data analysis programs coupled with an infrastructure to evaluate these programs. The infrastructure layer consists of a compiler that produces sequences of Map-Reduce programs. The language layer consists of a textual language called *Pig Latin*.

The following sections provide documentation about installing, upgrading, configuring and using Pig. You can also refer to the documentation available on the [Apache Pig](#) website.

### Configure Pig

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Pig runs in MapReduce mode by default. If you want to run Pig in local mode (`pig -x local`), add the following properties to the `/opt/mapr/pig/pig-<version>/conf/pig.properties` file:

```
fs.file.impl=org.apache.hadoop.fs.LocalFileSystem
io.file.buffer.size=4096
```

The `io.file.buffer.size` property defines how much data is buffered during read and write operations. This value defaults to `-1`, which causes Pig to fail if the local filesystem is used.

### Use Pig

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Once Pig is installed, the executable is located in `/opt/mapr/pig/pig-<version>/bin/pig`.

The following topics provide information about using Pig. You can also refer to the documentation available on the [Apache Pig](#) website.

### Get Started with Pig

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

In this tutorial, we will use Pig to run a MapReduce application that counts the words in the `/in/constitution.txt` file located in the `mapr` user's directory on the cluster, and store the results in the file `wordcount.txt`.

1. Download the ZIP file that contains [constitution.txt](#) and then extract the `constitution.txt` file.
2. Load the file onto the cluster and place it in the directory `/user/mapr/in`.
3. In the terminal, type the command `pig` to start the Pig shell.
4. At the `grunt>` prompt, type the following lines (press ENTER after each): After you type the last line, Pig starts a MapReduce application to count the words in the file `constitution.txt`.

```
A = LOAD '/user/mapr/in' USING TextLoader() AS (words:chararray);
```

```
B = FOREACH A GENERATE FLATTEN(TOKENIZE(*));
```

```
C = GROUP B BY $0;
```

```
D = FOREACH C GENERATE group, COUNT(B);
```

```
STORE D INTO '/user/mapr/wordcount';
```

5. When the MapReduce application is complete, type `quit` to exit the Pig shell and take a look at the contents of the directory `/myvolume/wordcount` to see the results.

### Use ORC Storage with Pig

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

This section presents simple examples for using Hive ORC storage. Use the `grunt` shell in Pig to execute the commands. For more details, see the [Pig documentation](#).

ORC is typically used to read (load) and write (store) data as follows:

```
<VAR_NAME> = load '/path/to/orc/formatted/file' using OrcStorage();
store <VAR_NAME> into '/path/to/output/orc/file' using OrcStorage('');
```

*Example: Create an ORC file in the file system by storing the data in a Hive table and uploading it to Pig*

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

You can create an ORC format file in the file system by using Hive to load a text file into a table with ORC storage. Then, you can upload the resulting ORC format file to Pig.

1. Create a sample test data file:

```
cd /home/mapr
nano test_pig.data
chown mapr:mapr test_pig.data
```

## 2. Add data to the file.

```
John,Smith
Brian,May
Rodger,Taylor
John,Deacon
Max,Plank
Freddie,Mercury
Albert,Einstein
Fedor,Dostoevsky
Lev,Tolstoy
Niccolo,Paganini
```

**Note:** Do not include any extra lines at the end of the file.

## 3. Upload the test data to a Hive table:

```
sudo -u mapr hive
hive> create table test_pig(first_name string, last_name string) ROW
FORMAT DELIMITED FIELDS TERMINATED BY ',';
hive> load data local inpath '/home/mapr/test_pig.data' overwrite into
table test_pig;
```

## 4. Create a Hive table with ORC storage:

```
hive> create table test_pig_orc(first_name string, last_name string)
stored as orc tblproperties ("orc.compress"="NONE");
hive> insert overwrite table test_pig_orc select * from test_pig;
hive> select * from test_pig_orc;
```

## 5. Check that the ORC file was created:

```
hadoop fs -ls /user/hive/warehouse/test_pig_orc
```

## 6. Upload the ORC file to Pig:

```
sudo -u mapr pig
grunt> B = load '/user/hive/warehouse/test_pig_orc/000000_0'
using OrcStorage();
grunt> dump B;
```

**Example: Upload a text file to the file system and use Pig to save it as an ORC file**

### 1. Upload the file to the file system:

```
cd /home/mapr
sudo -u mapr hadoop fs -put ./test_pig.data /test_pig.data
sudo -u mapr hadoop fs -mkdir /output
```

### 2. Start Pig and save the text file in ORC format:

```
sudo -u mapr pig
grunt> A = LOAD '/test_pig.data' using PigStorage(',') AS
(first_name:chararray, last_name:chararray);
grunt> store A into '/output/A' using OrcStorage('');
```

3. Verify that the ORC file was created:

```
hadoop fs -ls /output/A/
```

### Integrate Pig

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The following topics provide information about how to integrate Pig with other ecosystem components. You can also refer to the documentation available on the [Apache Pig](#) website.

### Integrate Pig and HBase

This document shows an example of a Pig and HBase integration. The goal of integration is to upload data from the filesystem to Pig and then move the data to an HBase table.

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

### Configuring Pig and HBase

No additional configuration is needed to integrate HBase and Pig.

### Pig and HBase Integration Example

1. Create sample data, and upload the data to the filesystem:

- a. Create a sample data file:

```
vim input.csv
```

- b. Add data to the file:

```
1,aaa,bbb
2,ccc,ddd
3,rrr,fff
4,ttt,yyy
```

- c. Upload the data to the filesystem:

```
hadoop fs -put input.csv /user/mapr/input.csv
```

2. Create a sample table in HBase:

- a. Start the HBase shell:

```
hbase shell
```

- b. Create a table:

```
hbase(main):012:0> create 'sample_names', 'info'
```

3. Load the data to Pig, and store the data in HBase:

- a. Start the Pig shell:

```
pig
```

- b. Load the data to Pig:

```
raw_data = LOAD '/user/mapr/input.csv' USING PigStorage(',') AS
(listing_id: chararray, fname: chararray, lname: chararray);
```

- c. Store the data in HBase:

```
STORE raw_data INTO 'sample_names' USING
org.apache.pig.backend.hadoop.hbase.HBaseStorage ('info:fname
info:lname');
```

4. Verify the data in HBase:

- a. Start the HBase shell:

```
hbase shell
```

- b. Query the data:

```
hbase(main):017:0* scan 'sample_names'
```

The result is:

```
ROW
COLUMN+CELL

1 column=info:fname, timestamp=1574946889082, value=aaa
1 column=info:lname, timestamp=1574946889082, value=bbb
2 column=info:fname, timestamp=1574946889091, value=ccc
2 column=info:lname, timestamp=1574946889091, value=ddd
3 column=info:fname, timestamp=1574946889091, value=rrr
3 column=info:lname, timestamp=1574946889091, value=fff
4 column=info:fname, timestamp=1574946889091, value=ttt
4 column=info:lname, timestamp=1574946889091, value=yyy
```

### Integrate Pig and HPE Ezmeral Data Fabric Database

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

To configure Pig to work with HPE Ezmeral Data Fabric Database tables, perform the following steps:

1. On the client node where Pig is installed, add the following string to `/opt/mapr/conf/env.sh`:

```
export PIG_CLASSPATH=$PIG_CLASSPATH:/location-to-hbase-jar
```

- If the client node where Pig is installed also has the `mapr-hbase` package installed, add the location of the `hbase-<version>.jar` file to the `PIG_CLASSPATH` variable from the previous step:

```
export PIG_CLASSPATH="$PIG_CLASSPATH:/opt/mapr/hbase/hbase-<version>/hbase-<version>.jar"
```

- If the client node where Pig is installed does not have the `mapr-hbase` package installed, copy the HBase JAR from a node that does have HBase installed to a location on the Pig client node. Add the HBase JAR's location to the definition from previous steps:

```
export PIG_CLASSPATH=$PIG_CLASSPATH:/opt/mapr/lib/hbase-<version>.jar
```

- Add the HBase JAR to the Hadoop classpath:

```
export HADOOP_CLASSPATH="/opt/mapr/hbase/hbase-<version>/hbase-<version>-mapr.jar:$HADOOP_CLASSPATH"
```

- Launch a Pig job and verify that Pig can access HBase tables by using the HBase table name directly. Do not use the `hbase://` prefix.

### Pig 0.16.0 API

-  **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

This section contains the following topics:

#### New API in Pig 0.16.0

-  **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Pig 0.16.0 includes the following new classes and interfaces.

#### New Classes

| Class                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">org.apache.pig.piggybank.evaluation.string.REPLACE_MULTI</a> | <p>REPLACE_MULTI implements eval function to replace all occurrences of search keys with replacement values. Replacement values are specified in Map. For example:</p> <pre>input_data = LOAD 'input_data' as (name); -- name = 'Hello World!' replaced_name = FOREACH input_data \ GENERATE REPLACE_MULTI ( name, [ '#_', '!#', 'e#a', 'o#oo' ] ); -- replaced_name = Halloo_Woorld</pre> <p>The first argument is the source string on which REPLACE_MULTI operation is performed. The second argument is a map having search key with replacement value pairs.</p> |

| Class                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">org.apache.pig.piggybank.storage.apachelog.LogFormatLoader</a>                                         | This is a pig loader that can load Apache HTTPD access logs written in (almost) any Apache HTTPD LogFormat.<br><br><i>Basic usage:</i> Feed the loader your (custom) logformat specification and it will show the fields that can be extracted from this logformat.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <a href="#">org.apache.pig.CounterBasedErrorHandler</a>                                                            | Handles errors thrown by the <code>StoreFuncInterface.putNext()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <a href="#">org.apache.pig.backend.hadoop.HKerberos</a>                                                            | Support for logging in using a Kerberos keytab file.<br><br>Kerberos is an authentication system that uses tickets with limited validity time. Running a Pig script on a Kerberos secured Hadoop cluster limits the running time to at most the remaining validity time of the Kerberos tickets. When doing really complex analytics, this may become a problem as the job may need to run for a longer time than these ticket times allow. A Kerberos keytab file is a Kerberos specific form of the password of a user. It is possible to enable a Hadoop job to request new tickets when they expire by creating a keytab file and making it part of the job that is running in the cluster. This will extend the maximum job duration beyond the maximum renew time of the Kerberos tickets. |
| <a href="#">org.apache.pig.backend.hadoop.executionengine.mapReduceLayer.PigWritableComparators</a>                | Byte only raw comparators for faster comparison for non-orderby jobs. This does not reuse <code>JobControlCompiler.Pig&lt;DataType&gt;WritableComparator</code> , which extends <code>PigWritableComparator</code> . The <code>PigNullablePartitionWritable.compare</code> is not that efficient in cases where tuple is iterated for null checking instead of taking advantage of <code>TupleRawComparator.hasComparedTupleNull()</code> . This also skips multi-query index checking.                                                                                                                                                                                                                                                                                                          |
| <a href="#">org.apache.pig.backend.hadoop.executionengine.physicalLayer.relationalOperators.StoreFuncDecorator</a> | This class is used to decorate the <code>StoreFunc#putNext(Tuple)</code> . It handles errors by calling <code>OutputErrorHandler#handle(String, long, Throwable)</code> if the <code>StoreFunc</code> implements <code>ErrorHandling</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <a href="#">org.apache.pig.backend.hadoop.executionengine.tez.runtime.PigInputFormatTez</a>                        | Extends <code>org.apache.hadoop.mapreduce.InputFormat</code> and implements Pig and Tez specific functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <a href="#">org.apache.pig.backend.hadoop.executionengine.tez.util.TezUDFContextSeparator</a>                      | Extends a visitor for the <code>TezOperPlan</code> class and serializes all ( <code>LoadFunc</code> , <code>StoreFunc</code> , <code>UserFunc</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <a href="#">org.apache.pig.impl.io.compress.BZip2CodecWithExtensionBZ</a>                                          | For historical reasons, Pig supports <code>.bz</code> and <code>.bz2</code> for <code>bzip2</code> extension. This class returns the additional <code>bzip2</code> file extension, <code>.bz</code> , as a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <a href="#">org.apache.pig.impl.util.UDFContextSeparator</a>                                                       | <code>TezUDFContextSeparator</code> extends <code>PhyPlanVisitor</code> , which is the visitor class for the Physical Plan. To use this, create the visitor with the plan to be visited. Call the <code>visit()</code> method to traverse the plan in a depth first fashion.<br><br>This class also visits the nested plans inside the operators. Extend this class to modify the nature of each visit and to maintain any relevant state information between the visits to two different operators.                                                                                                                                                                                                                                                                                             |
| <a href="#">org.apache.pig.parser.RegisterResolver</a>                                                             | Resolves a JAR with a scripting language or namespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Class                                                 | Description                                  |
|-------------------------------------------------------|----------------------------------------------|
| <a href="#">org.apache.pig.tools.DownloadResolver</a> | Makes a list of URIs of the downloaded JARs. |

### New Interfaces

| Interface                                    | Description                                                                                  |
|----------------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">org.apache.pig.ErrorHandler</a>  | The interface that handles errors thrown by <code>StoreFuncInterface.putNext(Tuple)</code> . |
| <a href="#">org.apache.pig.ErrorHandling</a> | The interface to enable handling of errors during <code>StoreFunc#putNext(Tuple)</code> .    |

### Deprecated API in Pig 0.16.0

 **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The following interfaces, classes, fields, and methods have been deprecated in Pig 0.16.0.

### Deprecated Interfaces

| Instead of this deprecated interface...    | Use...                           |

| <a href="#">org.apache.pig.impl.util.WrappedIOException</a> |  <b>Note:</b> This class was introduced to overcome the limitation that before Java 1.6, IOException did not have a constructor which took a Throwable argument. Since Pig code is now compiled with Java 1.6 and EvalFunc and LoadFunc user implementations should also use Java 1.6, they can use IOException instead. From Java 1.6, IOException has constructors which take a Throwable argument. |

## Sentry

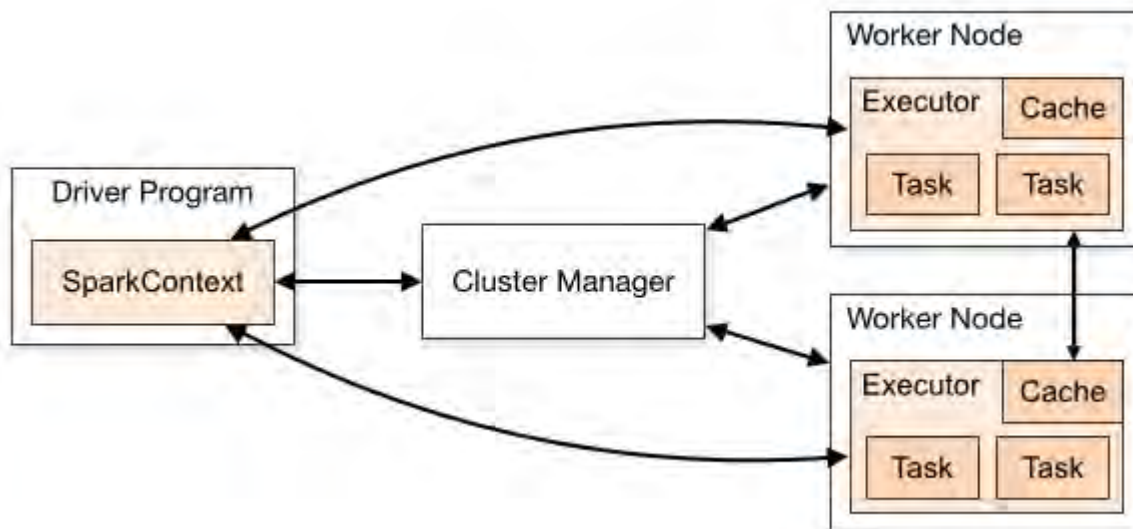

**Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

The Sentry documentation has moved. Sentry documentation can now be found at [Sentry](#) on page 4026.

## Apache Spark

Apache Spark is an open-source processing engine that you can use to process Hadoop data. The following diagram shows the components involved in running Spark jobs. See [Spark Cluster Mode Overview](#) for additional component details.

HPE Ezmeral Data Fabric supports the following types of cluster managers:

- Spark's standalone cluster manager
- YARN

The configuration and operational steps for Spark differ based on the Spark mode you choose to install. The steps to integrate Spark with other components are the same when using either Standalone or YARN cluster mode, except where otherwise noted.

This section provides documentation about configuring and using Spark with HPE Ezmeral Data Fabric, but it does not duplicate the [Apache Spark](#) documentation.

You can also refer to additional documentation available on the [Apache Spark Product Page](#).

### Getting Started with Spark Interactive Shell

After you have a basic understanding of Apache Spark and have it installed and running on your cluster, you can use it to load datasets, apply schemas, and query data from the Spark interactive shell.

### Reading Data from filesystem

#### 1. Copy sample data into filesystem:

- For this example, the dataset constitutes a CSV file of a list of auctions.
- Download the file from GitHub: <https://github.com/mapr-demos/getting-started-spark-on-mapr/tree/master/data>.
- Copy the file into your cluster, in the `/apps/` directory, using the `cp/scp` or `hadoop put` command:

```
scp ./data/auctiondata.csv mapr@[mapr-cluster-node]:/mapr/[cluster-name]/apps/
or
$ hadoop fs -put ./data/auctiondata.csv /apps
```

- This dataset is from eBay online auctions. The dataset contains the following fields:

```
auctionid - Unique identifier of an auction.
bid - Proxy bid placed by a bidder.
bidtime - Time (in days) that the bid was placed from the start of the auction.
bidder - eBay username of the bidder.
```

```

bidderrate - eBay feedback rating of the bidder.
openbid - Opening bid set by the seller.
price - Closing price that the item sold for (equivalent to the second
highest bid + an increment).
item - Type of item.

```

The table below shows the fields with some sample data:

| auctionid      | bid | bidtime  | bidder   | bidderrate | openbid | price | item | daystolive |
|----------------|-----|----------|----------|------------|---------|-------|------|------------|
| 821303470<br>5 | 95  | 2.927373 | jake7870 | 0          | 95      | 117.5 | xbox | 3          |

**2. Start the Spark interactive shell:**

- \$SPARK\_HOME represents the home of your Spark installation in MapR, for example: /opt/mapr/spark/spark-2.2.1/.

```
$ $SPARK_HOME/bin/spark-shell --master local[2]
```

**3. Once the Spark shell is ready, load the dataset:**

```
scala> val auctionData = spark.read.textFile("/apps/auctiondata.csv")
```

**4. Display the first entry:**

```
scala> auctionData.first()
```

**5. Count the number of entries:**

```
scala> auctionData.count()
```

**6. Use other Spark actions:**

```
// Displays first 20 lines
scala> auctionData.show()

// Displays first 3 lines - change value to see more/less
scala> auctionData.take(3)
```

**7. Transform the dataset into a new one that contains only xbox lines, and count them:**

```
scala> val auctionWithXbox = auctionData.filter(line =>
line.contains("xbox"))
scala> auctionWithXbox.count()
```

- This could also be done in a single line by chaining transformations and actions:

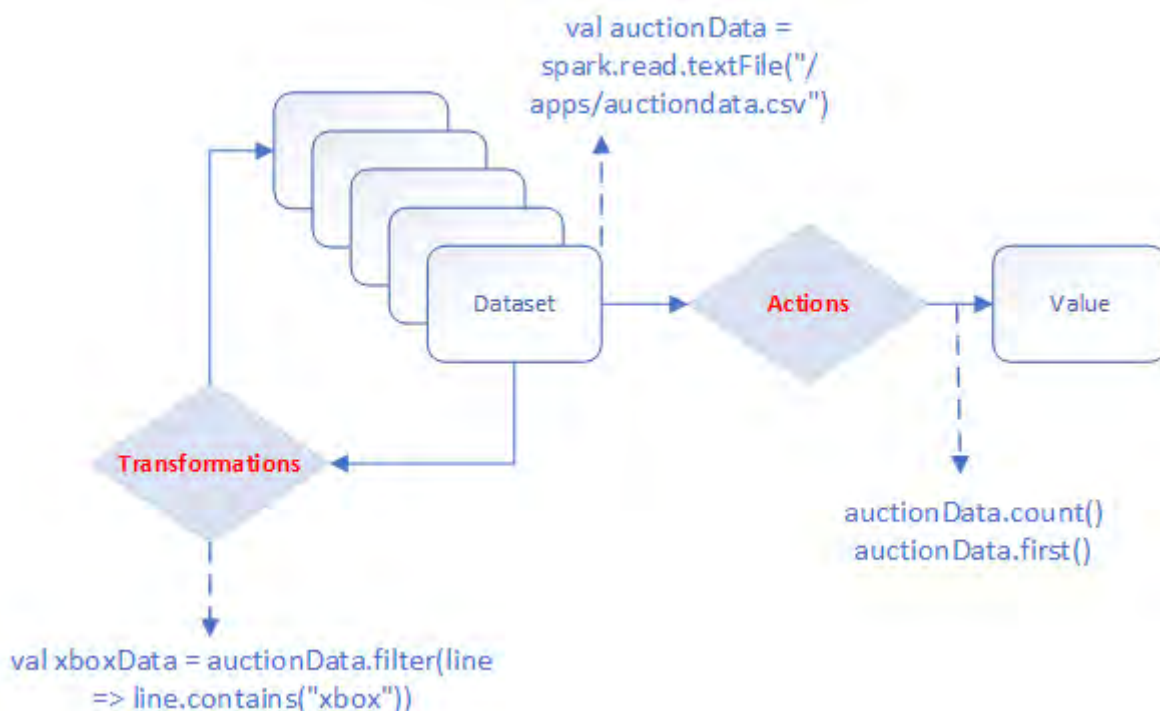

```
scala> auctionData.filter(line => line.contains("xbox")).count()
```

## 8. Use Spark Dataframes:

```
scala> val auctionDataFrame =
spark.read.format("csv").option("inferSchema",
true).load("/apps/
auctiondata.csv").toDF("auctionid", "bid", "bidtime", "bidder", "bidderrate",
"openbid", "price", "item", "daystolive")
```

## 9. Use a filter transformation on the Dataframe:

```
scala> auctionDataFrame.filter($"price" < 30).show()
```

**Figure 34: Schematic representation of performing transformations and actions on a dataset**

### Writing Data from filesystem

Using the same dataset, save all xbox items as a file in filesystem:

- You can use the `filter($"item" === "xbox")` filter and `write.json` or other options to save the result of the action to filesystem.

```
scala> auctionDataFrame.filter($"item" === "xbox").write.json("/apps/
results/json/xbox")
```

This command creates the `/apps/results/json/xbox` directory in which you will see the JSON file(s) created. You can use the same command to create Parquet or any other file format:

```
scala> auctionDataFrame.filter($"item" === "xbox").write.parquet("/apps/
results/parquet/xbox")
```

## Writing Data to HPE Ezmeral Data Fabric Database JSON

The first step when you are working with HPE Ezmeral Data Fabric Database JSON is to define a document `_id` that uniquely identifies the document.

Add a new `_id` field in the csv file and generate UUIDs to add to this field.

To load the Dataframe into the MapR-DB JSON:

```
dataframe.saveToMapRDB("tableName", createTable = true, bulkInsert = false,
idFieldPath = "_id")
```

The following commands will create a table and insert the data into: `/apps/auction_json_table`.

```
scala> import spark.implicits._
scala> import java.util.UUID
scala> import org.apache.spark.sql.SparkSession
scala> import org.apache.spark.sql.types._
scala> import org.apache.spark.sql.SaveMode
scala> import com.mapr.db.spark.sql._ // import the MapR-DB OJAI Connector
scala> val generateUUID = udf(() => UUID.randomUUID().toString) // create
UDF to generate UUID
scala> // showing that you can create your own schema
 val customSchema =
 StructType(
 Array(
 StructField("actionid", StringType, true),
 StructField("bid", DoubleType, true),
 StructField("bidtime", DoubleType, true),
 StructField("bidder", StringType, true),
 StructField("bidderrate", IntegerType, true),
 StructField("openbid", DoubleType, true),
 StructField("price", DoubleType, true),
 StructField("item", StringType, true),
 StructField("daystolive", IntegerType, true)
)
)
```

You can now query the table using the HPE Ezmeral Data Fabric Database shell. Open a terminal on your cluster and run the following command:

```
$ mapr dbshell
maprdb mapr:> find /apps/auction_json_table --limit 10
```

## Reading Data from HPE Ezmeral Data Fabric Database JSON

Now that you have the data in HPE Ezmeral Data Fabric Database JSON, you can create and query a Spark Dataframe using the following commands:

```
scala> import com.mapr.db.spark.sql._
scala> import org.apache.spark.sql.SparkSession
scala> val dataFromMapR = spark.loadFromMapRDB("/apps/auction_json_table")
scala> dataFromMapR.printSchema
scala> dataFromMapR.count

scala> dataFromMapR.filter($"price" < 30).show() // use a filter
```

### Related Links

- [Spark configure.sh](#) on page 4261

**GPU Aware Scheduling Support on Spark**

HPE Ezmeral Data Fabric does not support GPU aware scheduling feature on Spark 3.1.2 and Spark 3.2.0. You must have Hadoop 3.x to support the GPU aware scheduling feature on Spark 3. However, EEP 8.x.x supports Hadoop 2.7.6 and thus YARN will not be able to allocate the GPU resources for the Spark Applications.

**Spark SQL and Apache Derby Support on Spark**

If you are using Spark SQL with Derby database without Hive or Hive Metastore installation, you will see the following exception:

```
java.lang.RuntimeException: Unable to
instantiate
org.apache.hadoop.hive.ql.metadata.Ses
sionHiveMetaStoreClient
```

Add the `hive-service-2.3.*.jar` and `log4j2` jars to `/opt/mapr/spark/spark-3.x.x/jars` location to use Spark SQL with Derby Database without Hive or Hive Metastore installation.

The `log4j2` jars are located at `/opt/mapr/lib/log4j2/log4j-*.jar` location.

Spark 3.1.2 and Spark 3.2.0 does not support `log4j1.2` logging on HPE Ezmeral Data Fabric.

**Spark Thrift JDBC/ODBC Server Support**

Running the Spark Thrift JDBC/ODBC Server on a secure cluster is supported only on Spark 2.1.0 or later.

You can run the Spark Thrift JDBC/ODBC Server to enable connections to Hive 1.2.1 using Beeline; however, you can connect only to Hive versions supported by your Spark version.

**Spark SQL and Hive Support for Spark 2.1.0**

Spark 2.1.0 is able to connect to Hive 2.1 Metastore; however, only features of Hive 1.2 are supported.

**Spark SQL and Hive Support for Spark 2.0.1**

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#).

The following Hive functions are not supported in Spark SQL:

- Tables with buckets
- UNION type
- Unique join
- Column statistics collecting
- Output formats: File format (for CLI), Hadoop Archive
- Block-level bitmap indexes and virtual columns
- Automatic determination of the number of reducers for JOIN and GROUP BY
- Metadata-only query
- Skew data flag

- STREAMTABLE hint in JOIN
- Merging of multiple small files for query results

### Spark SQL and Hive Support for Spark 1.6.1

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#). The following Spark SQL operations support the following Hive table formats:

|                      | Hive 1.2 Table Format |     |         |     |         |
|----------------------|-----------------------|-----|---------|-----|---------|
| Spark SQL Operations | AVRO                  | ORC | Parquet | RC  | default |
| create               | Yes                   | Yes | Yes     | Yes | Yes     |
| drop                 | Yes                   | Yes | Yes     | Yes | Yes     |
| insert into          | Yes                   | Yes | Yes     | Yes | Yes     |
| insert overwrite     | Yes                   | Yes | Yes     | Yes | Yes     |
| select               | Yes                   | Yes | Yes     | Yes | Yes     |
| load data            | Yes                   | Yes | Yes     | Yes | Yes     |

### Spark Standalone

This section includes topics about configuring and using Spark in Standalone mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#).

For additional documentation, see the [Apache Spark website](#).

#### Installing Spark Standalone

This topic describes how to use package managers to download and install Spark Standalone from the EEP repository.

To set up the EEP repository, see [Step 10: Install Ecosystem Components Manually](#) on page 164.

Spark is distributed as four separate packages:

| Package                  | Description                                                                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mapr-spark               | Install this package on any node where you want to install Spark. This package is dependent on the <code>mapr-client</code> , <code>mapr-hadoop-client</code> , <code>mapr-hadoop-util</code> , and <code>mapr-librdkafka</code> packages.             |
| mapr-spark-master        | Install this package on Spark master nodes. Spark master nodes must be able to communicate with Spark worker nodes over SSH without using passwords. This package is dependent on the <code>mapr-spark</code> and the <code>mapr-core</code> packages. |
| mapr-spark-historyserver | Install this optional package on Spark History Server nodes. This package is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.                                                                                             |
| mapr-spark-thriftserver  | Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.                                             |

Run the following commands as `root` or using `sudo`.

1. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory.

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

**Note:** Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically.

2. Install Spark using the appropriate commands for your operating system:

#### On CentOS 8.x / Red Hat 8.x

```
dnf install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On Ubuntu

```
apt-get install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On SLES

```
zypper install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

**Note:** The `mapr-spark-historyserver`, `mapr-spark-master`, and `mapr-spark-thriftserver` packages are optional.

Spark is installed into the `/opt/mapr/spark` directory.

3. For Spark 2.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

For Spark 3.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/workers.template` into `/opt/mapr/spark/spark-<version>/conf/workers`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

For example:

```
localhost
worker-node-1
worker-node-2
```

4. Set up [passwordless ssh](#) for the `mapr` user such that the Spark master node has access to all secondary nodes defined in the `conf/slaves` file for Spark 2.x and `conf/workers` file for Spark 3.x.

- As the `mapr` user, start the worker nodes by running the following command in the master node. Since the Master daemon is managed by the Warden daemon, do not use the `start-all.sh` or `stop-all.sh` command.

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

- If you want to integrate Spark with HPE Ezmeral Data Fabric Event Streams, install the Streams Client on each Spark node:

- On Ubuntu:

```
apt-get install mapr-kafka
```

- On RedHat/CentOS:

```
yum install mapr-kafka
```

- If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the HPE Ezmeral Data Fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).
- After installing Spark Standalone but before running your Spark jobs, follow the steps outlined at [Configuring Spark Standalone](#) on page 4252.

### Configuring Spark Standalone

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run [configure.sh -R](#) as the final step in the configuration process.

#### *Configure High Availability for SparkMaster*

You configure high availability for the Spark Primary instance so that the instance does not become the single point of failure.

By using ZooKeeper to provide leader election and some state storage, you can launch multiple primary nodes in your cluster that are connected to the same ZooKeeper instance. Zookeeper elects one primary node to be the "leader," and the others remain in standby mode. If the leader goes down, Zookeeper elects another primary node, recovers the old primary node's state, and resumes scheduling.

- Set `SPARK_DAEMON_JAVA_OPTS` in `spark-env.sh` with the appropriate ZooKeeper information for the cluster.

```
export SPARK_DAEMON_JAVA_OPTS="-Dspark.deploy.recoveryMode=ZOOKEEPER
-Dspark.deploy.zookeeper.url=<zookeeper1:5181,zookeeper2:5181,...>
-Djava.security.auth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.sasl.client=false
```

- Restart the Spark Primary instance and Spark History Server services:

- For Spark 2.0.1 and later:

```
maprcli node services -nodes <node-ip> -name spark-master -action
restart
```

- For Spark 1.6.1:

```
maprcli node services -nodes <node-ip> -name spark-master -action
restart
maprcli node services -nodes <node-ip> -name
spark-historyserver -action restart
```

3. On the primary node, restart the Spark Secondary instances as the `mapr` user.

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-slaves.sh
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-workers.sh
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

### *Configure Scratch Directory for Spark Standalone*

By default, Spark uses the `/tmp` directory as scratch space. Map output files and RDDs are stored in the scratch directory. To use a different directory, or a comma-separated list of multiple directories, set `SPARK_LOCAL_DIRS` to the path to the new directory by adding the following line to the `$SPARK_HOME/conf/spark-env.sh` file:

```
export SPARK_LOCAL_DIRS=$SPARK_HOME/<path to scratch directory>
```

Make this change before starting the Spark services.

### **Community Edition (Without NFS Support)**

Reserve space on your local disk to use as the scratch directory for Spark.

### **Enterprise Edition and Enterprise Database Edition (With NFS Support)**

Create a local volume on each node with the `maprcli volume create` command, or from the Control System. Mount that local volume with NFS to a directory. Set that directory as the scratch directory for Spark.

**Note:** Due to <https://issues.apache.org/jira/browse/SPARK-6313>, make sure to set `spark.files.useFetchCache=false` in your `spark-defaults.conf` file.

### **Using Spark Standalone**

For a simple test of your Spark installation, run the following command:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master spark://<Spark
Master node hostname>:7077 SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/spark-<version>/bin/run-example org.apache.spark.examples.SparkPi 10
```

For more information about running Spark applications, see the [Apache Spark Documentation](#).

#### *Run the Spark Shell in Standalone Mode*

- To run the Spark shell, use the following command:

- On Spark 2.0.1 and later:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell --master spark://<Spark Master node hostname>:7077
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/spark-<version>/bin/spark-shell
```

### Security with Spark Standalone

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the MapR installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See [Spark configure.sh](#) on page 4261 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

### Spark on YARN

This section contains topics about installing, configuring and using Spark on YARN.

 **Important:** Spark 2.0.1 (and later) YARN mode is supported only on clusters in MRv2 (YARN) mode. It is not supported on clusters in MRv1 (classic) mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#) on page 4336

For additional documentation, see the [Apache Spark](#) documentation.

### Installing Spark on YARN

This topic describes how to use package managers to download and install Spark on YARN from the EEP repository.

To set up the EEP repository, see [Step 10: Install Ecosystem Components Manually](#) on page 164.

Spark is distributed as three separate packages:

| Package                  | Description                                                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mapr-spark               | Install this package on any node where you want to install Spark. This package is dependent on the <code>mapr-client</code> , <code>mapr-hadoop-client</code> , <code>mapr-hadoop-util</code> , and <code>mapr-librdkafka</code> packages. |
| mapr-spark-historyserver | Install this optional package on Spark History Server nodes. This package is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.                                                                                 |

| Package                 | Description                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mapr-spark-thriftserver | Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages. |

To install Spark on YARN (Hadoop 2), execute the following commands as `root` or using `sudo`:

1. Verify that JDK 11 or later is installed on the node where you want to install Spark.
2. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory:

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

**Note:** Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically when using the Installer. However, you must manually create this directory when performing a manual installation.

3. Install the packages:

#### On Ubuntu

```
apt-get install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On CentOS 8.x / Red Hat 8.x

```
dnf install mapr-spark
mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On SLES

```
zypper install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

**Note:** The `mapr-spark-historyserver` and `mapr-spark-thriftserver` packages are optional.

4. If you want to integrate Spark with HPE Ezmeral Data Fabric Event Streams, install the Streams Client on each Spark node:

- **On Ubuntu:**

```
apt-get install mapr-kafka
```

- **On CentOS / Red Hat:**

```
yum install mapr-kafka
```

5. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the `data-fabric` Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<version>/jars/`).

For repository-specific information, see [Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4371

- After installing Spark on YARN but before running your Spark jobs, follow the steps outlined at [Configuring Spark on YARN](#) on page 4256.

### Configuring Spark on YARN

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run `configure.sh -R` as the final step in the configuration process.

#### *Configure data-fabric Client Node to Run Spark Applications*

When Spark runs on YARN, data-fabric client nodes require the `hadoop-yarn-server-web-proxy` JAR file to run Spark applications. On Windows, the client node also requires an update to the `SPARK_DIST_CLASSPATH`. A data-fabric client node (a node with the `mapr-client` package, but without `mapr-core` packages) is also known as an edge node.

The `mapr-client` package does not include the JAR file required to run Spark applications. Therefore, you must copy the `/opt/mapr/hadoop/hadoop-2.x.x/share/hadoop/yarn/hadoop-yarn-server-web-proxy-<version>.jar` from a data-fabric cluster node to the same location on the data-fabric client node from which you want to run the Spark application.

#### *Configure Spark JAR Location*

By default, Spark on YARN uses Spark JAR files that are installed locally. The Spark JAR files can also be added to a world-readable location on filesystem. When you add the JAR files to a world-readable location, YARN can cache them on nodes to avoid distributing them each time an application runs. Complete the following steps to add the Spark JAR files to a world-readable location on filesystem:

- Create a zip archive containing all the JARs from the `SPARK_HOME/jars` directory. For example:

```
cd /opt/mapr/spark/spark-<version>/jars/
zip /opt/mapr/spark/spark-<version>/spark-jars.zip ./*
```

- Copy the zip file from the local filesystem to a world-readable location on filesystem. You can upload it to the home of the current user:

```
hadoop fs -put /opt/mapr/spark/spark-<version>/spark-jars.zip
```

For example:

```
hadoop fs -put /opt/mapr/spark/spark-3.2.0/spark-jars.zip /user/mapr/
```

- Set the `spark.yarn.archive` property in the `spark-defaults.conf` file located in `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` to point to the world-readable location where you added the zip file. Apply this setting on the node where you will be submitting your Spark jobs.

```
spark.yarn.archive maprfs:///<path to zip>
```

For example:

```
spark.yarn.archive maprfs:///user/mapr/spark-jars.zip
```

#### *Configure Spark with the NodeManager Local Directory Set to filesystem*

This procedure configures Spark to use the mounted NFS directory instead of the `/tmp` directory on the local filesystem. Note that spill to disk should be configured to spill to the filesystem node local storage only if local disks are unavailable or space is limited on those disks.

1. Install the `mapr-loopbacknfs` and `nfs-utils` packages if they are not already installed. For reference, see [Installing the mapr-loopbacknfs Package](#) on page 353 and [Setting Up MapR NFS](#).
2. Start the `mapr-loopbacknfs` service by following the steps at [Managing the mapr-loopbacknfs Service](#) on page 1354.
3. To configure Spark Shuffle on NFS, complete these steps **on all nodes**:
  - a) Create a local volume for Spark Shuffle:

```
sudo -u mapr maprcli volume
create -name mapr.${hostname -f}.local.spark -path /var/mapr/local/${
hostname -f}/spark -replication 1 -localvolumehost ${hostname -f}
```

- b) Point the NodeManager local directory to the Spark Shuffle volume mounted through NFS by setting the following property in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml` file on the NodeManager nodes:

```
<property>
 <name>yarn.nodemanager.local-dirs</name>
 <value>/mapr/my.cluster.com/var/mapr/local/${mapr.host}/spark</
value>
</property>
```

- c) (Optional) Configure how many times the NodeManager can attempt to delete application-related directories from a volume when Spark is configured to use the mounted NFS directory instead of the `/tmp` directory on the local filesystem. Increasing the value (default is 2) of this property can prevent application cache data from accumulating in the volume. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See [Applying a Patch](#).

```
<property>
 <name>yarn.nodemanager.max-retry-file-delete</name>
 <value>2</value>
</property>
```

- d) Restart the NodeManager service and the Resource Manager service on the main node to pick up the `yarn-site.xml` changes:

```
maprcli node services -name nodemanager -action restart -nodes <node
1> <node 2> <node 3>
maprcli node services -name resourcemanager -action restart -nodes
<node 1> <node 2> <node 3>
```

### Using Spark on YARN

This section includes information about using Spark on YARN in a data-fabric cluster.

For a simple test of your Spark installation, run the following command as the `mapr` user:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master
yarn --deploy-mode client SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=yarn-client /opt/mapr/spark/spark-<version>/bin/run-example
org.apache.spark.examples.SparkPi 10
```

**Note:** These commands will fail if it is run as the root user.

For more information about running Spark applications, see the [Apache Spark documentation](#).

### Deployment Modes

Spark is preconfigured for YARN and does not require any additional configuration to run.

Two deployment modes can be used to launch Spark applications on YARN:

- In `cluster` mode, jobs are managed by the YARN cluster. The Spark driver runs inside an Application Master (AM) process that is managed by YARN. This means that the client can go away after initiating the application.
- In `client` mode, the Spark driver runs in the client process, and the Application Master is used only to request resources from YARN.

MapR recommends using `cluster` deployment mode instead of `client` mode. If the Spark client that runs the job exits after submitting the job, there is no impact on job completion.

**Note:** In `cluster` deployment mode, the local directories used by the Spark executors and the Spark driver are the local directories that are configured for YARN (`yarn.nodemanager.local-dirs`).

**Note:** `SPARK_LOCAL_DIRS` is ignored when you run Spark on YARN.

### Run Spark from the Spark Shell

In `yarn-client` mode, complete the following steps to run Spark from the Spark shell:

1. Navigate to the Spark-on-YARN installation directory, and insert your Spark version into the command.

```
cd /opt/mapr/spark/spark-<version>/
```

2. Issue the following command to run Spark from the Spark shell:

- On Spark 2.0.1 and later:

```
./bin/spark-shell --master yarn --deploy-mode client
```

- On Spark 1.6.1:

```
MASTER=yarn-client ./bin/spark-shell
```

**Note:** You must use `yarn-client` mode to run Spark from the Spark shell. The `yarn-cluster` mode is not supported.

### Security with Spark on YARN

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the MapR installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See [Spark configure.sh](#) on page 4261 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

#### Configure Authentication for Spark on YARN

When authentication is enabled, authentication keys are randomly generated for each job.

**Note:** Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#), as the final step in the configuration process, enables these settings.

Complete the following step to manually configure authentication on a non-secure cluster or in versions earlier than EEP 4.0:

1. Configure the following property in the `spark-defaults.conf` file on each Spark node:

```
spark.authenticate true
```

The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`

2. If you have configured an external shuffle service, you must also add the following property to [`yarn-site.xml`](#) on page 2501 on each Spark node:

```
<property>
 <name>spark.authenticate</name>
 <value>>true</value>
</property>
```

#### Configure SSL Encryption for Spark on YARN

Starting in EEP 8.0.0, if you are Non-Admin user starting a Spark Application, you must generate the KeyStore and KeyStore password and set it in Spark configuration files. For details, see [Security - Spark 3.1.2 Documentation](#). Otherwise, KeyStore and default KeyStore password generates automatically.

Starting in EEP 6.0.0, you can remove `spark.ssl.keyStorePassword`, `spark.ssl.trustStorePassword`, and `spark.ssl.keyPassword` from the `spark-defaults.conf` file for additional security. These passwords are stored in the `/opt/mapr/conf/ssl-client.xml` file and Spark can access passwords from this file itself.

**Note:** If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-2.3.1/conf/spark-defaults.conf` files, then the password from the `spark-defaults.conf` file is used.

Complete the following step to manually configure encryption for the Spark HTTP file and broadcast servers:

In the `spark-defaults.conf` file on each spark node, configure the following properties.

Starting in EEP 6.0.0, the configured algorithms mentioned in the following code are no longer available for your web service to pick up. You must remove the `spark.ssl.enabledAlgorithms TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA` line to let parties negotiate the matching ciphers.

- For Spark 2.0.1 and later:

```
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
```

**Note:** Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#), as the final step in the configuration process, enables these settings.

- For Spark 1.6.1:

```
spark.ssl.akka.enabled true
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
```

Spark UI SSL is not needed when running Spark on YARN because encryption is provided by the YARN protocol. **For versions prior to EEP 4.1.0**, to enable users logged in with a normal user account (not mapr or root) to run spark jobs on the cluster, disable Spark SSL for Spark-on-YARN jobs. To disable Spark SSL, add `spark.ssl.ui.enabled false` to the `spark-defaults.conf` file on each spark node. The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`. Make sure SSL is enabled for the Spark history server.

When you manually configure encryption for Spark, set the same protocol and algorithms for each node. Otherwise, the connection between those components might fail.

#### *Configure SASL Encryption for Spark on YARN*

**Note:** Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#), as the final step in the configuration process, enables these settings.

Complete the following steps to manually enable SASL encryption on a non-secure cluster or in versions earlier than EEP 4.0:

1. Verify that authentication is enabled, or configure authentication. SASL encryption uses the same authentication keys.

For more information, see [Configure Authentication for Spark on YARN](#) on page 4259

2. Configure the following property in the `spark-defaults.conf` file on each spark node.

```
spark.authenticate.enableSaslEncryption true
```

The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`

### Spark configure.sh

Starting in the EEP 4.0 release, run `configure.sh -R` to complete your Spark configuration when manually installing Spark or upgrading to a new version.

The command is the following:

```
/opt/mapr/server/configure.sh -R
```

**Note:** You do not need to run this script for new installs, if you are using the MapR installer in EEP 4.0 or later.

In the case of [Spark Standalone](#) on page 4250 and [Spark on YARN](#) on page 4254, this is the last step in the configuration process.

All security configuration properties are specified within the following comment block in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
#SECURITY BLOCK
...
#END OF THE SECURITY CONFIGURATION BLOCK
```

**Important:** Do not remove these comments from the file, as well as any other comments within the block inserted by `configure.sh`. The script uses these comments to locate security properties.

**Note:** To set ports to special values, use the `spark.driver.port` and `spark.blockManager.port` properties.

Starting in EEP 6.0.0, Spark services such as the History Server, Thrift Server, or Master are restarted by `configure.sh` only for changes to the following Spark configuration files: `spark-defaults.conf`, `spark-env.sh`, `hive-site.xml`, or `log4j.properties`. If these files are unchanged, `configure.sh` does not restart any of the Spark services.

An update to Spark causes the `conf` directory from the previous the Spark version to be saved to the `spark-<old-version>.<old-timestamp>` directory. If your Spark version did not change during the update, then configurations from the `spark-<old-version>.<old-timestamp>` directory is automatically copied to the `spark-<version>` directory by the `configure.sh` script.

If you use `.customSecure`, at the first run, the `configure.sh` script copies the `hive-site.xml` file from Hive. For subsequent times, the `hive-site.xml` file is not copied from Hive and you would need to manually modify the `$SPARK_HOME/conf/hive-site.xml` file.

### Spark SQL Thrift Server

Spark SQL Thrift (Spark Thrift) was developed from Apache Hive HiveServer2 and operates like HiveServer2 Thrift server.

Spark Thrift is supported on secure clusters. You can run the Spark Thrift server and connect to Hive versions supported by Spark 2.1.0 and later with Business Intelligence (BI) tools or the Beeline command-line tool.

Starting in the EEP 4.0 release, the Spark Thrift server is available as a separate package. To install this package, see [Installing Spark Standalone](#) on page 204 or [Installing Spark on YARN](#) on page 206, depending on the type of cluster manager you are installing.

In EEP 3.0, MapR introduces additional security mechanisms for Spark with the Spark Thrift server. MapR-SASL and Kerberos are supported:

- For JDBC connections into Spark Thrift server
- Between Spark and Hive metastore

To enable these security mechanisms for the Spark Thrift server, starting in the EEP 4.0 release, for secure clusters, running `configure.sh -R` configures MapR-SASL security. The script modifies or creates a `SPARK_HOME/conf/hive-site.xml` file as follows:

- If Hive is installed in your cluster, the script copies `HIVE_HOME/conf/hive-site.xml` to `SPARK_HOME/conf` and modifies the file.
- If Hive is not installed and you are using MapR-SASL security, the script creates a new `SPARK_HOME/conf/hive-site.xml` file.
- Each time the script runs, if there is a pre-existing `SPARK_HOME/conf/hive-site.xml` file, the script saves a copy of the file in `SPARK_HOME/conf/hive-site.xml.old` before modifying it.

You can configure security manually by following the steps outlined in sub-topics listed on this page.

To launch the Spark Thrift server, perform the procedures required to configure [Apache Spark](#) on page 4243 to use [Hive](#) on page 3618.

### ! Important:

- Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 10000.
- Starting in the EEP 5.0.4 and EEP 6.3.0 releases, if you start and stop the Spark Thrift server by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 2304.

### Default Behavior

The default behavior of the Spark Thrift server is as follows:

1. After installation, the Spark Thrift server is started in the local master mode.
2. If the Spark master package is installed, then Spark Thrift server is started in the standalone master mode.
3. If the `spark.master` property is set in the `spark-defaults.conf` file, then Spark Thrift server uses the master set by this property.

## Known Limitations

- MapR-SASL support is implemented for Spark 2.1.0 and later versions of Spark. For Spark version information, see [Component Versions for Released EEPs](#) on page 5789.
- The ODBC drivers do not support MAPR-SASL.
- Username and password authentication through PAM is not supported in EEP 3.0.
- Spark Thrift server supports only features and commands in Hive 1.2.
- Although Spark 2.1.0 can connect to Hive 2.1 Metastore, only Hive 1.2 features and commands are supported by Spark 2.1.0.

## Related Links

For information related to Spark Thrift server, see:

| MapR                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Apache                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• Hive Release Notes:               <ul style="list-style-type: none"> <li>• <a href="#">Hive 1.2.1-1703 Release Notes</a> on page 6197</li> <li>• <a href="#">Hive 2.1-1703 Release Notes</a> on page 6189</li> </ul> </li> <li>• <a href="#">Hive and Tez</a></li> <li>• <a href="#">Integrate Spark SQL with Hive</a></li> <li>• <a href="#">Hive</a></li> <li>• <a href="#">Authentication for HiveServer2</a></li> <li>• <a href="#">Spark Feature Support</a></li> </ul> | <ul style="list-style-type: none"> <li>• <a href="#">Apache Spark 2.1.0 Security</a></li> <li>• <a href="#">Apache Thrift</a></li> <li>• <a href="#">Setting Up HiveServer2</a></li> </ul> |

## Spark Thrift Server Clients

With Spark Thrift server, you can use JDBC and ODBC connection interfaces that enable a variety of external tools to access Spark and run SQL queries.

- The ODBC interface is used by BI tools (often produced by HPE Ezmeral Data Fabric partners such as [Tableau](#) or [Microstrategy](#)).
- The JDBC interface is used by clients such as Squirrel SQL or the Beeline simple SQL shell.

MapR Hive JDBC clients that connect to HiveServer2 can also connect to Spark Thrift server without additional configuration. For details about clients, see [HiveServer2 Clients](#) and [Connecting to HiveServer2](#).

**Important:** Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number is 10000. Beginning with EEP 6.3.0, the connection port number is 2304 for both start/stop methods (using Warden and using `thriftserver.sh` scripts).

## MapR-SASL JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for MapR-SASL environments is:

```
jdbc:hive2://<hostname>:2304/default;auth=maprsasl;ssl=true
```

Otherwise, the port you use depends on the EEP version:

|                              |                                                                                 |
|------------------------------|---------------------------------------------------------------------------------|
| <b>EEP 4.0 through 6.2.x</b> | <code>jdbc:hive2://&lt;hostname&gt;:10000/default;auth=maprsasl;ssl=true</code> |
| <b>EEP 6.3.0 and later</b>   | <code>jdbc:hive2://&lt;hostname&gt;:2304/default;auth=maprsasl;ssl=true</code>  |

### Kerberos JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for clusters secured with Kerberos is:

```
jdbc:hive2://<hostname>:2304/default;principal=mapr/<FQDN@REALM>;ssl=true
```

Otherwise, the port you use depends on the EEP version:

|                              |                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <b>EEP 4.0 through 6.2.x</b> | <code>jdbc:hive2://&lt;hostname&gt;:10000/default;principal=mapr/&lt;FQDN@REALM&gt;;ssl=true</code> |
| <b>EEP 6.3.0 and later</b>   | <code>jdbc:hive2://&lt;hostname&gt;:2304/default;principal=mapr/&lt;FQDN@REALM&gt;;ssl=true</code>  |

### Starting the Thrift Server on a Custom Port

To start the Spark Thrift Server on a custom port, use the `hive.server2.thrift.port` option. For example, you can specify the following in the `/opt/mapr/spark/spark-2.4.4/conf/hive-site.xml` file:

```
<property>
<name>hive.server2.thrift.port</name>
<value>34512</value>
</property>
```

For more information, see the [Apache HiveServer2](#) documentation.

### Using Authentication with Spark Thrift Server

Spark Thrift server supports both MapR-SASL and Kerberos authentication. The authentication method that you configure for the Spark Thrift server determines how the connection is secured. Clients might require additional configuration and specific connection strings based on the authentication type.

To enable authentication, see:

- [Configuring Spark Thrift Server with MapR-SASL](#) on page 4265
- [Configuring Spark Thrift Server with Kerberos](#) on page 4265

To configure PAM for Spark Thriftserver, run `configure.sh` on the secure cluster.

For information about Hive integration, see:

- [Integrate Spark SQL with Hive](#)
- [Setting Up HiveServer2](#)
- [Hive](#)

- [Spark Feature Support](#)

### Configuring Spark Thrift Server with MapR-SASL

Describes how to enable and start the Spark Thrift server on all nodes.

You can configure Spark Thrift server to use MapR-SASL for its communications with various components on a secure data-fabric cluster. Minimal configuration is required.

**Note:** Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To manually enable MapR-SASL authentication on a non-secure cluster or in versions earlier than EEP 4.0:

1. Verify that the `hive.server2.authentication` property in `hive-site.xml` is set to the value, `MAPRSASL`.

```
<property>
 <name>hive.server2.authentication</name>
 <value>MAPRSASL</value>
</property>
```

2. Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

**Important:** The data-fabric administrative user (generally, the account named `mapr`) should start the Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

### Bringing up the Spark Thrift server on every node

When you start and stop Warden after enabling Spark or after running [configure.sh](#) on page 2331 or after installing a patch, Spark starts only on one (1) node and not on all nodes. This happens because by default, the Warden configuration file for Spark has the value `1` instead of `all`. For example:

```
grep services /opt/mapr/conf/conf.d/warden.spark-thriftserver.conf
services=spark-thriftserver:1:cldb
```

To fix this issue permanently:

1. Modify `/opt/mapr/spark/spark-2.4.0/warden/warden.spark-thriftserver.conf` and change `1` to `all`:

```
grep services /opt/mapr/spark/spark-2.4.0/warden/
warden.spark-thriftserver.conf
 services=spark-thriftserver:all:cldb
```

2. Run `/opt/mapr/server/configure.sh -R`.

The change is then propagated to the `/opt/mapr/conf/conf.d/warden.spark-thriftserver.conf` file.

### Configuring Spark Thrift Server with Kerberos

You can configure Spark Thrift server to use Kerberos for its communications with various components on a secure MapR cluster if necessary.

**Note:** MapR clusters do not provide Kerberos infrastructure. The information in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

To enable Kerberos authentication:

1. Create a Kerberos identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file.

- The `hive.keytab` file must be owned and readable only by the `mapr` user.
- `FQDN@REALM` is case-sensitive.

```
kadmin
: addprinc -randkey mapr/<FQDN@REALM>
: ktadd -k /opt/mapr/conf/hive.keytab mapr/<FQDN@REALM>
```

2. Configure the following properties in `hive-site.xml` on each node where HiveServer2 is installed:

| Property                                                    | Value                                                                                                                                  |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>hive.server2.authentication</code>                    | KERBEROS                                                                                                                               |
| <code>hive.server2.authentication.kerberos.principal</code> | <code>mapr/FQDN@REALM</code><br>(where <code>mapr/FQDN@REALM</code> is the principal that you want to use for the Spark Thrift server) |
| <code>hive.server2.authentication.kerberos.keytab</code>    | <code>/opt/mapr/conf/mapr.keytab</code><br>(where <code>/opt/mapr/conf/mapr.keytab</code> is path to the keytab that must be used)     |

```
<property>
 <name>hive.server2.authentication</name>
 <value>KERBEROS</value>
 <description>authenticationtype</description>
</property>
<property>
 <name>hive.server2.authentication.kerberos.principal</name>
 <value>mapr/FQDN@REALM</value>
 <description>Spark Thrift server principal. If _HOST is used as
the FQDN portion,
 it will be replaced with the actual hostname of the running
instance.
 </description>
</property>
<property>
 <name>hive.server2.authentication.kerberos.keytab</name>
 <value>/opt/mapr/conf/mapr.keytab</value>
 <description>Keytab file for Spark Thrift server principal</
description>
</property>
```

3. Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where HiveServer2 is installed:

**Note:** These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env\\_override.sh](#) on page 2576.

| Existing Configuration                                                                                                   | Required Configuration                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <pre>MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop .login=maprsasl_keytab" MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login= maprsasl"</pre> | <pre>MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid" MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"</pre> |

- Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

**Important:** The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

### Related Links

For information about working with HiveServer, see:

- [Setting Up HiveServer2](#)
- [Hive](#)

### Configuring Spark Thrift Server Encryption

Spark Thrift server encryption is supported when authentication is enabled. You can configure encryption with MapR SASL or with SSL/TLS.

#### Configuring Encryption with MapR SASL or Kerberos

Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done using MapR Installer, the Installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To manually configure encryption with MapR-SASL or Kerberos authentication on a non-secure cluster or in versions earlier than EEP 4.0, complete the following steps:

- Set the `hive.server2.thrift.sasl.qop` property in `hive-site.xml` to the value `auth-conf`. The SASL Quality of Protection (QOP), or `sasl.qop`, setting and the authentication with confidentiality (`auth-conf`) value support authentication:

```
<property>
 <name>hive.server2.thrift.sasl.qop</name>
 <value>auth-conf</value>
</property>
```

- Restart Spark Thrift server to apply the change:

**Important:** The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files are owned by this user, and impersonation support (where applicable) functions correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

## Configuring Encryption with SSL/TLS

To enable encryption with SSL/TLS:

- Add the following properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

```
spark.ssl.enabled true
spark.ssl.fs.enabled true
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.protocol TLSv1.2
spark.ssl.keyStorePassword mapr123
spark.ssl.trustStorePassword mapr123
```

After the properties are added, event logs will indicate that the job is encrypted.

- To connect using Beeline with encryption, add the following properties to the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file:

```
<property>
 <name>hive.server2.use.SSL</name>
 <value>true</value>
 <description>enable/disable SSL </description>
</property>

<property>
 <name>hive.server2.keystore.path</name>
 <value>/opt/mapr/conf/ssl_keystore</value>
 <description>path to keystore file</description>
</property>

<property>
 <name>hive.server2.keystore.password</name>
 <value>mapr123</value>
 <description>keystore password</description>
</property>
```

- To start the Spark Thriftserver, use the following command:

```
/opt/mapr/spark/spark-<version>/sbin/start-thriftserver.sh --hiveconf
hive.server2.thrift.port=2304 --master yarn --deploy-mode client
```

The following example shows a connection string using Beeline (PAM+SSL):

```
./bin/beeline
Beeline version 1.2.0-mapr-1808-spark by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connecting to jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connected to: Spark SQL (version 2.1.0-mapr-mep-3.x-1808)
Driver: Hive JDBC (version 1.2.0-mapr-1808-spark)
Transaction isolation: TRANSACTION_REPEATABLE_READ
1: jdbc:hive2://node1.cluster.com:2304/default>
```

### Enabling High Availability for Spark Thrift Server

With EEPs 5.0.4 or 6.3.0 and later, you can enable high availability for the Spark Thrift Server. Note the following characteristics of high availability for the Spark Thrift Server:

- Unlike a HiveServer2 high-availability (HA) configuration, all Spark Thrift Servers are in an active state. ZooKeeper keeps track of the Thrift Servers. ZooKeeper chooses one of them to work and makes a record of the choice. If one of the Thrift Servers goes down, ZooKeeper looks for another Thrift Server, makes a record, and works with it.
- After configuration, you can use Beeline to connect to the Spark Thrift Server on each node. The Control System displays one thrift server as active with the others on standby, but you can connect to any of them.
- If a Spark Thrift Server stops or fails, ZooKeeper removes the record for the failed Spark Thrift Server, and the client connects to the next one in the ZooKeeper list.
- At its core, the running Spark Thrift Server is a job that you can start in YARN mode. This makes it possible to configure queues for the Spark Thrift Server in a multi-tenant cluster if high availability is enabled. You can do this by using the `./sbin/start-thriftserver` script and applying the special properties that YARN provides for managing queues.
- You don't need to configure load balancing. Spark handles load-balancing automatically through the use of parallelized requests and efficient resource management.

To enable high availability, use the following steps:

- Install Spark Thrift Server on all the cluster nodes where it is needed:

#### On Ubuntu

```
apt-get install
mapr-spark-thriftserver
```

#### On Red Hat / CentOS

```
yum install mapr-spark-thriftserver
```

#### On SLES

```
zypper install
mapr-spark-thriftserver
```

2. Add the following properties to the `/opt/mapr/spark/spark-<spark_version>/conf/hive-site.xml` file on all the nodes where the Spark Thrift Server is installed

```
<property>
<name>hive.zookeeper.quorum</name>
<value><zk_host1_>,<zk_host_2>,...,<zk_host_n></value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value><zk_port></value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value><zk_namespace></value>
</property>
```

For example:

```
<property>
<name>hive.zookeeper.quorum</name>
<value>node1.cluster.com,node2.cluster.com,node3.cluster.com</value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value>5181</value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value>ts2-ts2</value>
</property>
```

**Note:** The values that you provide for the `hive.server2.zookeeper.namespace` property should be different for the `hive-site.xml` in the Spark and Hive directories.

- Restart the Spark Thrift Server to apply the changes following the script in the `.sbin` directory at `/opt/mapr/spark/spark-<spark_version>/` or by running a `maprcli` command on all configured nodes:

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

or

```
maprcli node services -nodes <host_1>,<host_2>,<host_n> -name
spark-thriftserver -action restart
```

- Launch the Zookeeper command line interface, and check the Spark Thriftserver znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

For example:

```
/opt/mapr/zookeeper/zookeeper-3.4.11/bin/zkCli.sh -server
node1.cluster.com:5181
ls /ts2-ts2
[serverUri=node1.cluster.com:2304;version=;sequence=0000000000]
```

- Using Beeline, you can connect to the Spark Thrift Server by using the following string:

```
beeline> !connect jdbc:hive2://<hostname -f>:5181/
default;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=<hive.server2.z
ookeeper.namespace>;
```

For example:

```
./bin/beeline
Warning: Unable to determine $DRILL_HOME
Beeline version 1.2.0-mapr-spark-MEP-6.0.0-1912 by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
Connecting to jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
20/03/29 21:38:19 WARN MaprSaslClient: SASL Server qopProperty:

 **Note:** High availability for the Spark Thrift Server can be used in conjunction with HiveServer2 high availability. For more information about HiveServer2 high availability, see [Enabling High Availability for Hive](#) on page 3751.

### Spark History Server SSL

Describes how to enable SSL for Spark History Server.

 **Note:** For secure clusters, Spark History Server UI authentication is enabled by default. If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-<spark_version>/conf/spark-defaults.conf` files, the password from the `spark-defaults.conf` file is used

Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To configure SSL manually in a non-secure cluster or in versions earlier than EEP 4.0, add the following properties to the `spark-default.conf` file:

```
#HistoryServer https configure
spark.yarn.historyServer.address <Spark History Server node
hostname>:18480
spark.ssl.protocol tls
spark.ssl.historyServer.enabled true
spark.ssl.trustStore $MAPR_HOME/conf/ssl_truststore
spark.ssl.keyStore $MAPR_HOME/conf/ssl_keystore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.keyStorePassword <ssl-keystore-password>
```

 **Note:** If a cluster is secure and you use unsecured ports with HTTP, you will be automatically redirected to HTTPS with secure ports. For example, if on the secure cluster you go to `http://node1:18080`, you will be redirected to `https://node1:18480`.

### HPE Ezmeral Data Fabric Database Connectors for Apache Spark

This section describes the HPE Ezmeral Data Fabric Database connectors that you can use with Apache Spark.

[Apache Spark](#) is a software framework that is used to process data in memory in a distributed manner. Spark is replacing MapReduce in many use cases. The HPE Ezmeral Data Fabric Database Connectors for Spark enable users to write applications that access HPE Ezmeral Data Fabric Database JSON and Binary tables.

#### Understanding the HPE Ezmeral Data Fabric Database OJAI Connector for Spark

Using the HPE Ezmeral Data Fabric Database OJAI connector for Spark enables you build real-time and batch pipelines between your data and HPE Ezmeral Data Fabric Database JSON. Before getting started, it is important that you understand Spark terminology and workflow, system requirements and support, and OJAI connector and API features.

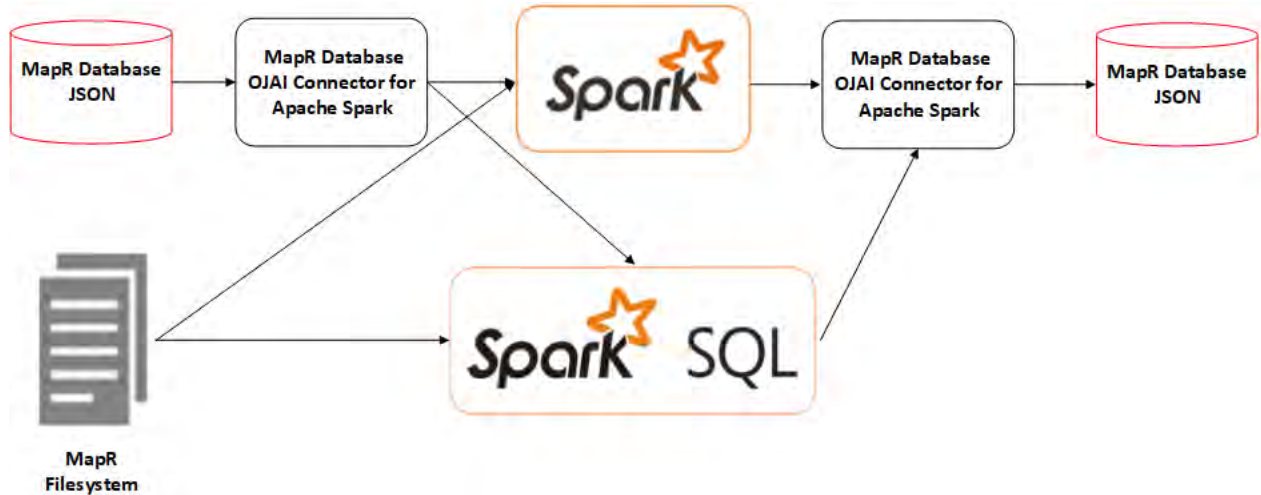

The HPE Ezmeral Data Fabric Database OJAI connector includes a set of APIs that enable you to write applications that consume HPE Ezmeral Data Fabric Database JSON tables and use them in Spark. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark is a companion to the [HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark](#) on page 4324, which provides the equivalent functionality for HPE Ezmeral Data Fabric Database Binary tables.

#### HPE Ezmeral Data Fabric Database OJAI Connector with Spark Workflow

You can use the HPE Ezmeral Data Fabric Database OJAI Connector to extract data from HPE Ezmeral Data Fabric Database or filesystem and transform that data using either Spark or Spark SQL, and then

load it into HPE Ezmeral Data Fabric Database JSON:

### HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark Features

Principal features of the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark include the following:

- Support for Scala and, beginning with EEP 4.1, Java and Python APIs

This matrix shows the programming languages and features supported:

|           | Scala | Java | Python |
|-----------|-------|------|--------|
| RDD       | Yes   | Yes  | No     |
| DataFrame | Yes   | Yes  | Yes    |
| Dataset   | Yes   | Yes  | No     |
| DStream   | Yes   | No   | No     |

- APIs that enable you to load data from a HPE Ezmeral Data Fabric Database JSON table to an Apache Spark RDD, DataFrame, or Dataset
- Projection and filter pushdown for better performance
- Custom partitioner for RDDs that enables you to partition data for better performance
- APIs that save an Apache Spark RDD, DataFrame, or DStream to a HPE Ezmeral Data Fabric Database JSON table using either normal or bulk insert
- Support for Scala and Java bean classes
- Support for data locality
- Support for secondary indexes starting from EEP 7.0.0 and EEP 6.3.1.

The following features are not supported:

- HPE Ezmeral Data Fabric Database Binary tables

Only HPE Ezmeral Data Fabric Database JSON tables are supported; access to HPE Ezmeral Data Fabric Database binary tables is provided through the HPE Ezmeral Data Fabric Database Binary Connector.

- Secondary indexes are not supported for previous EEP 7.0.0 and EEP 6.3.1 versions.

## Supported Product Versions and System Requirements

To use the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must have the following minimum software versions:

- MapR: 5.2.1 or later
- EEP 3.0 or later
- Spark 2.1.0 or later
- Scala 2.11 or later
- Java 8 or later

Support for DataFrames and Datasets is available starting in the EEP 4.0 release.

## OJAI API

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark uses the [OJAI API](#) internally to access HPE Ezmeral Data Fabric Database JSON tables.

## Related information

[Spark SQL, DataFrames and Datasets Guide](#)

[Spark Streaming Programming Guide](#)

*Configuring the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark*

Before using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must edit the `pom.xml` file for your project.

Add the Spark core dependency into the `pom.xml` file:

**Note:** If all dependent JAR files are already present on the node, consider setting the `scope` parameter to `provided`. For example:

```
<scope>provided</scope>
```

Setting the scope this way reduces the size of the JAR file.

```
<dependency>
 <groupId>org.apache.spark</groupId>
 <artifactId>spark-core_<scala_version></artifactId>
 <version><spark_artifact_version></version>
</dependency>
```

Add the Spark Maven dependency to the `pom.xml` file:

```
<dependency>
 <groupId>com.mapr.db</groupId>
 <artifactId>maprdb-spark</artifactId>
 <version><spark_artifact_version></version>
</dependency>
```

For example, see the dependencies for Spark 2.4.4.0 (EEP 6.3.0 release):

```
<dependency>
 <groupId>org.apache.spark</groupId>
 <artifactId>spark-core_2.11</artifactId>
 <version>2.4.4.0-mapr-630</version>
```

```
</dependency>
<dependency>
 <groupId>com.mapr.db</groupId>
 <artifactId>maprdb-spark</artifactId>
 <version>2.4.4.0-mapr-630</version>
</dependency>
```

To enable Maven to download dependencies, add the following repository information to the `pom.xml` file:

```
<repository>
 <id>mapr-releases</id>
 <url>https://repository.mapr.com/maven/</url>
 <snapshots>
 <enabled>>false</enabled>
 </snapshots>
 <releases>
 <enabled>>true</enabled>
 </releases>
</repository>
```

### Related concepts

[Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4371

Maven artifacts can be used for dependency management when developing applications based on the the HPE Ezmeral Data Fabric.

#### *Loading Data from HPE Ezmeral Data Fabric Database Using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark*

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports loading data as an Apache Spark RDD. Starting in the EEP 4.0 release, the connector introduces support for Apache Spark DataFrames and Datasets. DataFrames and Datasets perform better than RDDs. Whether you load your HPE Ezmeral Data Fabric Database data as a DataFrame or Dataset depends on the APIs you prefer to use. It is also possible to convert an RDD to a DataFrame.

#### Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD

You can use the following API to load JSON-format data from a HPE Ezmeral Data Fabric Database table into an Apache Spark RDD of a JSON document:

##### Scala

For loading as an RDD, apply the following method on a `SparkContext` object:

```
def loadFromMapRDB[T](table: String):
 RDD[T]
```

##### Java

For loading as an RDD, apply the following method on a `MapRDBJavaSparkContext` object:

```
mapRDBSparkContext.loadFromMapRDB(tableName: String, clazz: Class)
```

**Note:** The only required parameter to the methods is `tableName`. All the others are optional.

The following example creates a `userprofilesRDD` by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table ("`/tmp/user_profiles`"):

##### Scala

```
import com.mapr.db.spark._
val userprofilesRDD
```

**Java**

```
= sc.loadFromMapRDB("/tmp/
user_profiles")
```

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
```

The following example creates a `userInfo` RDD by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table ("`/tmp/UserInfo`"):

**Scala**

```
import com.mapr.db.spark._

val userInfo =
sc.loadFromMapRDB("/tmp/UserInfo")
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIIDocument> userInfo
=
mapRDBSparkContext.loadFromMapRDB("/tm
p/UserInfo")
```

In the previous example, the `userInfo` data contains the following information:

- Address (map type)
- Date of birth (date type)
- First name (string type)
- Interests (string type)
- Last name (string type)

The following prints the fields and shows the output for a sample user:

**Scala**

```
userInfo.foreach(println(_))
```

**Java**

```
usersInfo.foreach(System.out::println)
;
```

```
{
 "address":
 {"Pin":95035,"city":"milpitas","street":"350 holger way"},
 "dob":"1947-11-29",
 "first_name":"David",
 "interests":["football","books","movies"],
 "last_name":"Jones"
}
```

The following example shows a join operation performed on two different JSON documents using `address.city` as the join key:

**Scala**

```
import com.mapr.db.spark._

val maprd1 = sc.loadFromMapRDB("/tmp/
user_profiles")

val maprd2 = sc.loadFromMapRDB("/tmp/
user_income")

val collection = maprd1.map(a =>
(a.`address.city`[String],a))
.cogroup(maprd2.map(a=>(a.`address.cit
y`[String],a)))
.map(a =>
(a._1,a._2._1.size,a._2._2.size)).coll
ect
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import scala.Tuple2;
import scala.Tuple3;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument> maprd1 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
MapRDBJavaRDD<OJAIDocument> maprd2 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_income");

List collection =
maprd1.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a))
.cogroup(maprd2.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a)))
.map(a -> new Tuple3<>(a._1,
((Collection<?>)a._2._1).size(),
((Collection<?>)a._2._2).size()))
.collect();
```

The resulting RDD, `collection`, contains the count of the users in the `user_profiles` and `user_income` HPE Ezmeral Data Fabric Database tables.

The following example adds a new field into all the JSON documents:

#### Scala

```
import com.mapr.db.spark._

val maprd = sc.loadFromMapRDB("/tmp/
user_profiles")
val documents = maprd.map(a =>
{ a.`address.country` = "USA";
a}).collect
documents.saveToMapRDB("/tmp/
cleaned_user_profiles")
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIDocument> maprd =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<OJAIDocument> documents =
maprd.map(a ->
{a.set("address.country", "USA");
return a;})

.collect();
mapRDBSparkContext.saveToMapRDB(docume
nts, "/tmp/cleaned_user_profiles");
```

### Improving Performance by Using Projection Pushdown and Filter Pushdown

To improve performance, you can supply a `WHERE` clause and projection fields to the `loadFromMapRDB` API. In the following example, a condition is supplied to the `loadFromMapRDB` function and only certain fields are specified in the `SELECT` clause:

#### Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")

.where([condit
ion])
.select("addre
ss",
"first_name",
"_id",
"last_name")
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;
```

```

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles")

 .where([condition])

 .select("address",

 "first_name",

 "_id",

 "last_name");

```

The data is loaded based on the condition. The condition is pushed down to the server, and the server returns data based on the filtering. Only the fields specified in the SELECT clause are projected.

In the following example, the WHERE clause is used as a filter condition:

#### Scala

```

import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/user_profiles")
 .where(field("salary") >= 100)

```

#### Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaSparkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles")
 .where(MapRDB.newCondition().is("salary",
QueryCondition.Op.GREATER_OR_EQUAL,
100));

```

The userprofilesRDD includes only those documents with a salary field greater than 100.

By specifying an \_id field, you can find and retrieve a row for a given key:

#### Scala

```

import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/user_profiles")

```

```

 .where(field("_id")
d") === "k2")

```

### Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
 .where(MapRDB.newCon
dition().is("_id",
QueryCondition.Op.EQUAL, "k2"));

```

### WHERE Clause Semantics

The `loadFromMapRDB` API supports a WHERE clause to push down the filter to the JSON document API, ensuring that only relevant documents are propagated to the RDD.

You can use two options to provide the filter condition:

- Scala domain-specific language (DSL)
- `QueryCondition` (from OJAI API)

Following is an example of using `loadFromMapRDB` and supplying a condition by using Scala DSL:

### Scala

```

Condition isDoe = field("last_name")
=== "Doe"
val userprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles").where(isDoe)

```

For more information about using Scala DSL, see [Scala DSL for Specifying Filter Conditions](#) on page 4282.

Following is an example of passing the condition using the `QueryCondition` API:

### Scala

```

val maprd =
sc.loadFromMapRDB(tableName)
 .where(MapRDB.newConditio
n()
 .is("_id",
QueryCondition.Op.EQUAL, "k2")
 .build())

```

### Java

```

MapRDBJavaRDD rdd =
mapRDBJavaSparkContext.loadFromMapRDB(
tableName)
 .where(MapRDB.newConditio
n().is("_id",

```

```
QueryCondition.Op.EQUAL,
"k2").build());
```

For more information about `QueryCondition`, see [Querying with Conditions](#) on page 2918.

**Note:** For additional information, see [Java Examples](#) in the source code.

### Creating an Apache Spark RDD of a Class

When loading data as an Apache Spark RDD, if you have a custom class in your application, you can present the data as objects of your class.

#### Scala

You must define the custom class using Jackson semantics for Scala modules. The following example defines a custom `User` class:

```
case class User (@JsonProperty("_id")
id:String,

@JsonProperty("first_name")
firstName:String,

@JsonProperty("last_name") lastName:
String,
@JsonProperty("dob") dob:
ODate,

@JsonProperty("interests") interests:
List[String])
```

In the following example, by supplying `User` as a type parameter to the function while loading the HPE Ezmeral Data Fabric Database table, you can create an RDD of the `User` class:

```
val userprofilesRDD =
sc.loadFromMapRDB[User]("/tmp/
user_profiles")
 .where("conditio
n")
```

When specifying a bean class, the `SELECT` clause is unnecessary and is ignored.

#### Java

You must define a custom bean class as follows:

```
public static class Person implements
Serializable {
 private String _id;
 private String firstName;
 private String lastName;
 private Date dob;
 private Seq<String>
interests;
 public String get_id()
{ return _id; }
 public void set_id(String
_id) { this._id = _id; }
 public String
getFirstName() { return firstName; }
 public void
setFirstName(String firstName)
```

```

{ this.firstName = firstName; }
 public String
getLastName() { return lastName; }
 public void
setLastName(String lastName)
{ this.lastName = lastName; }
 public Date getDob()
{ return dob; }
 public void setDob(Date
dob) { this.dob = dob; }
 public Seq<String>
getInterests() { return interests; }
 public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
}

```

In the following example, by supplying the `User` bean class as a type parameter while loading the HPE Ezmeral Data Fabric Database table, you can create a `MapRDBJavaRDD` of the `User` class:

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles",
User.class).where(<condition>);

```

### Scala DSL for Specifying Filter Conditions

When loading data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD, you can use Scala DSL to specify filter conditions. This section shows examples of these filter conditions.

In the following examples, a class named `field` is introduced to represent a field in a condition. The `field` condition takes an argument as a `String`. The following table shows conditions written using Scala DSL:

| Condition   | Example                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------|
| equality    | <code>val idOnlyPredicate = field("_id") === "k2"</code>                                                   |
| greaterThan | <code>val simplePredicateWithComparisonOperator = field("a.c.d") &gt; 10</code>                            |
| notexists   | <code>val simpleNotExistsPredicate = field("a.c.e") notexists</code>                                       |
| IN          | <code>val inPredicate = field("a.c.d") in Seq(ODate.parse("2011-05-21"), ODate.parse("2013-02-22"))</code> |
| typeof      | <code>val simpleTypeOfPredicate = field("a.c.d") typeof "INT"</code>                                       |

| Condition                                                                  | Example                                                                                                                                           |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| complex condition with and                                                 | <pre>val inPredicateWithMapAndArray = (field("a.c.d") in Seq(5,10)) and   (field("a.c.e") notin Seq("aaa","bbb"))</pre>                           |
| another complex condition                                                  | <pre>val compositePredicateWithAndOnly = ((field("a.b") notexists ) and   (field("p.q")   typeof "DATE")) and   (field("a.c.d") &gt;   20L)</pre> |
| between                                                                    | <pre>val predicateWithBetweenOp = field("a.c.d") between   (ODate.parse("2015-01-15"),   ODate.parse("2015-05-15"))</pre>                         |
| predicate with equality check on Sequence of elements (representing array) | <pre>val eqPredicateWithList = field("a.b") === Seq(12345L, "xyz")</pre>                                                                          |
| predicate with equality check on a map                                     | <pre>val eqWithMapPredicate = field("a") === Map("k" -&gt; "kite",   "m" -&gt; "map")</pre>                                                       |

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- >
- >=
- <
- <=
- ===
- !=
- between
- exists
- notin
- in
- notexists
- typeof
- nontypeof
- like
- notlike

- matches
- notmatches
- sizeof

Here are examples for these operators:

- `field("a") > 10`
- `field("a") >= 10`
- `field("a") < 10`
- `field("a") <= 10`
- `field("a") === 10`
- `field("a") === Seq("aa", 10)`
- `field("a") === Map("aa" -> 10)`
- `field("a") != 10`
- `field("a") != Seq("aa", 10)`
- `field("a") != Map("aa" -> 10)`
- `field("a") between (10,20)`
- `field("a") exists`
- `field("a") notin Seq(10,20)`
- `field("a") in Seq(10, 20)`
- `field("a") notexists`
- `field("a") typeof "INT"`
- `field("a") nottypeof "INT"`
- `field("a") like "%s"`
- `field("a") notlike "%s"`
- `field("a") matches "*s"`
- `field("a") notmatches "*s"`

For `typeof`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`

- "STRING"
- "SHORT"
- "BYTE"
- "NULL"
- "FLOAT"
- "DOUBLE"
- "DECIMAL"
- "DATE"
- "TIME"
- "TIMESTAMP"
- "INTERVAL"
- "BINARY"
- "MAP"
- "ARRAY"

The `sizeOf` operator can have the following operations:

- `sizeOf(field("a")) === 10`
- `sizeOf(field("a")) < 10`
- `sizeOf(field("a")) > 10`
- `sizeOf(field("a")) >= 10`
- `sizeOf(field("a")) <= 10`
- `sizeOf(field("a")) != 10`

#### Java DSL for Specifying Filter Conditions

When loading data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD, you can use Java DSL to specify filter conditions. This section shows examples of these filter conditions.

| Condition    | Example                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| equality     | <pre>QueryCondition equality = MapRDB.newCondition().is("_id", QueryCondition.Op.EQUAL, "k2").build();</pre>                                                     |
| greatherThan | <pre>QueryCondition greatherThan = QueryCondition simpleWithComparisonOperator = MapRDB.newCondition().is("a.b.c", QueryCondition.Op.GREATER, 10).build();</pre> |

| Condition                  | Example                                                                                                                                                                                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| notexists                  | <pre>QueryCondition notexists = MapRDB.newCondition().notExists("a.c.e").build();</pre>                                                                                                                                                                                                              |
| IN                         | <pre>List&lt;ODate&gt; odateList = new ArrayList&lt;&gt;(); odateList.add(ODate.parse("2011-05-21")); odateList.add(ODate.parse("2013-02-22")); QueryCondition in = MapRDB.newCondition().in("a", odateList).build();</pre>                                                                          |
| typeof                     | <pre>QueryCondition typeof = MapRDB.newCondition().typeof("a.c.d", Value.Type.INT).build();</pre>                                                                                                                                                                                                    |
| complex condition with and | <pre>QueryCondition complexConditionWithAnd = MapRDB.newCondition() .and() .condition(MapRDB.newCondition().in("a", Arrays.asList(5, 10))) .condition(MapRDB.newCondition().notIn("b", Arrays.asList("aaa", "bbb"))) .close().build();</pre>                                                         |
| another complex condition  | <pre>QueryCondition anotherComplexCondition = MapRDB.newCondition() .and() .condition(MapRDB.newCondition().notExists("a.b")) .condition(MapRDB.newCondition().typeof("p.q", Value.Type.DATE)) .condition(MapRDB.newCondition().is("a.c.d", QueryCondition.Op.GREATER, 20L)) .close().build();</pre> |

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- is (LESS, LESS\_OR\_EQUAL, EQUAL, NOT\_EQUAL, GREATER\_OR\_EQUAL, GREATER)
- equals
- and
- exists
- in
- like
- matches
- notEquals
- notExists
- notIn
- notLike
- notMatches

- `notTypeOf`
- `or`
- `sizeof`
- `typeof`

Here are examples for these operators:

- `MapRDB.newCondition().is("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.NOT_EQUAL, 10);`
- `MapRDB.newCondition().exists("a");`
- `MapRDB.newCondition().notIn("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().in("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().notExists("a");`
- `MapRDB.newCondition().typeof("a", Value.Type.INT);`
- `MapRDB.newCondition().notTypeOf("a", Value.Type.INT);`
- `MapRDB.newCondition().like("a", "%s");`
- `MapRDB.newCondition().notLike("a", "%s");`
- `MapRDB.newCondition().matches("a", "*s");`
- `MapRDB.newCondition().notMatches("a", "*s");`

For `typeof`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`
- `"STRING"`
- `"SHORT"`
- `"BYTE"`
- `"NULL"`

- "FLOAT"
- "DOUBLE"
- "DECIMAL"
- "DATE"
- "TIME"
- "TIMESTAMP"
- "INTERVAL"
- "BINARY"
- "MAP"
- "ARRAY"

The `sizeof` operator can have the following operations:

- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.NOT_EQUAL, 10);`

Using the Custom Partitioner with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark  
In any distributed computing system, partitioning data is crucial to achieve the best performance. Apache Spark provides a mechanism to register a custom partitioner for partitioning the pipeline. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark includes a custom partitioner you can use to optimally partition data in an RDD.

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark's custom partitioner takes the following classes as keys:

- `String`
- `ByteBuffer` (as serializable `ByteBuffer`)

You can register this custom partitioner with either the `partitionBy` function or the `repartitionAndSortWithinPartitions` function.

The connector supports two versions of the custom partitioner. One version takes a HPE Ezmeral Data Fabric Database JSON table as an input. The partition information of the table is used to partition the data, so the `saveToMapRDB` call can use a `bulkInsert` to store the data. The `bulkInsert` option requires that you have the data already sorted on the `_id` key.

The other version of the custom partitioner takes an array of splits as an input.

### Specifying tablename for the Partitioner

If you already have a table that has been created and partitioned based on a set of keys, you can specify that the RDD be partitioned in the same way (using the same set of keys). In the following example, `/srctable` is provided as a reference partitioner for `/dsttable`:

#### Scala

```
sc.loadFromMapRDB("/srctable")
 .keyBy(doc =>
doc._id[String])
 .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String]("/dsttable"))
 .saveToMapRDB("/dsttable", createTable = false,
bulkInsert = true)
```

### Specifying a String Seq as an Array of Splits

In the following example, the first line creates an array of splits as `id1, id2 ... id9`. The rest of the example splits the RDD based on the array of splits:

#### Scala

```
val dstSplits: Array[String] = (1 to
9 by 3).map("id" + _).toArray
val partitionRDD =
sc.loadFromMapRDB("/srctable")
 .keyBy(doc =>
doc._id[String])
 .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String](dstSplits))
 .saveToMapRDB("/dsttable", createTable = true,
bulkInsert = true)
```

### Specifying a ByteBuffer Seq as an Array of Splits

Suppose you have an array of byte buffers to use as the array of splits for the partitioner. You must convert the byte buffers to serializable byte buffers first:

#### Scala

```
// Converting bytebuffer to
serializable bytebuffer
val dstSplits =
arrayOfByteBuffer.map(x =>
MapRDBSpark.serializableBinaryValue(x)
)
sc.loadFromMapRDB("/srctable")
 //KeyBy serializable bytebuffer
 .keyBy(doc =>
doc.getBinarySerializable(binaryField)
)
 .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner(dstSplits))
 .saveToMapRDB("/dsttable",
createTable = true, bulkInsert = true)
```

### Specifying tablename for the Partitioner with ByteBuffer as Id Fields

Suppose you have a table with keys that are binary or `ByteBuffer`, and you have an RDD with some rows and some values. You can repartition the RDD based on the partitions of the table. The following example reads the document from `/srctable`, but you could provide any table. In the second line, the example specifies a `keyBy` call on an ID that is binary serializable. In the last line, `/dsttable` is the RDD that has a key of serializable `ByteBuffers`:

#### Scala

```
sc.loadFromMapRDB("/srctable")
 .keyBy(doc =>
doc.getIdBinarySerializable())
 .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[ByteBuffer]
("/dsttable"))
```

**Note:** You must provide the key type of the `PairedRDD` on which the partitioning is specified. If the IDs are serializable bytebuffers, specify `ByteBuffer`. Otherwise, specify `String`.

After the data is partitioned with the custom partitioner, all the downstream transformations should be non-partition-changing transformations. Here is the code for passing on partitioner for an RDD:

#### Scala

```
user_profiles.repartitionAndSortWithin
Partitions
(MapRDBSpark.newPartitioner[String]
(<table-name>))
```

Or you can use the `partitionBy` function on the RDD:

#### Scala

```
user_profiles.partitionBy(MapRDBSpark.
newPartitioner[String](<table-name>))
```

The key of the data for this partitioner should be of the same type as that of the key of the table name. This partitioner yields a single partition if the table supplied to it is not pre-split. The number of partitions is calculated based on the table's existing tablet information.

For a table created with the `bulkInsert` option set to `true`, one of the following applies:

- If the table is pre-split, then the resulting partitions can be  $> 1$ .
- If the table is no-split, then the resulting partitions will be 1 if no partition information is available from the RDD lineage.

### Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark DataFrame

To load data from a HPE Ezmeral Data Fabric Database JSON table into an Apache Spark DataFrame, invoke the following API:

#### Scala

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](tableName:
String,
 schema: StructType):
DataFrame

import com.mapr.db.spark.sql._
```

**Java**

```
val df
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles"): DataFrame
```

For loading as a `DataFrame` (Datasets of Row), apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB(tableName: String,
schema: StructType, sampleSize:
Double): DataFrame

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
maprSession.loadFromMapRDB("/tmp/
user_profiles");
```

**Note:** Java supports only DataSets of Row (`Dataset<Row>`).

**Python**

For loading as a `DataFrame`, apply the following method on a `SparkSession` object:

```
loadFromMapRDB(table_name, schema,
sample_size)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")
```

**Note:** PySpark supports only DataFrames (`Dataset<Row>`).

**Note:** The only required parameter to the methods is `tableName`. All the others are optional.

This creates a `DataFrame` object corresponding to the HPE Ezmeral Data Fabric Database table specified by the `tableName` parameter.

Both `DataFrames` and HPE Ezmeral Data Fabric Database tables work with structured data. `DataFrames` need a fixed schema, whereas HPE Ezmeral Data Fabric Database allows for a flexible schema. When loading data into a `DataFrame`, you can map your data to a schema by specifying the `schema` parameter in the `loadFromMapRDB` call. You can also provide an application class as the type `[T]` parameter in the call. These two approaches are the preferred methods for loading data into `DataFrames`.

For data exploration use cases, you might not know the schema of your HPE Ezmeral Data Fabric Database table. For those situations, the HPE Ezmeral Data Fabric Database OJAI connector for Apache Spark can infer the schema by sampling data from the table.

Whenever possible, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark [pushes projections and filters](#) for better performance. This allows HPE Ezmeral Data Fabric Database to project and filter data before returning it to your client application.

The following subtopics describe these techniques.

## Optimizing HPE Ezmeral Data Fabric Database Lookups in Spark Jobs

The `lookupFromMapRDB()` API utilizes the primary and secondary indexes on a HPE Ezmeral Data Fabric Database table to optimize table lookups and outputs the results to an Apache Spark DataFrame.

 **Important:** The `lookupFromMapRDB()` API functionality requires a patch. The patch works with EEP 6.2.0 (Core 6.1.0, Spark 2.4.0.0) and EEP 6.3.0 (Core 6.1.0, Spark 2.4.4.0). To install patches, see [Applying a Patch](#)

The `loadfromMapRDB()` API in [MapR Database Connectors for Apache Spark](#) is optimized to load massive amounts of data from HPE Ezmeral Data Fabric Database tables with high throughput. In cases where a Spark job needs to lookup a small number of documents based on the equality (or short range) condition on a primary or secondary key, the `lookupFromMapRDB()` API should be used.

Invoke the `lookupFromMapRDB()` API when the filter conditions in short range and equality queries reference primary and secondary keys. If the filter condition references any non-primary keys (fields other than the `_id` field), a secondary index must exist on the secondary keys. Indexes on the filtering keys is essential to achieving reasonable performance of lookup queries in HPE Ezmeral Data Fabric Database tables.

The `lookupFromMapRDB()` API uses the secondary keys in indexes to lookup values in the primary table. For example, if a query contains the filter conditions `mydate = '2012-03-26'` and `myid = '120026015'`, a [secondary index](#) (of type composite) created on the `mydate` and `myid` fields must exist for the query to quickly output results.

Examples on the following tabs demonstrate how to invoke the `lookupFromMapRDB()` API to perform a lookup in a HPE Ezmeral Data Fabric Database table and output the results to an Apache Spark DataFrame:

### Scala

```
import com.mapr.db.spark.sql._
import spark.implicits._
val df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate" === "2012-03-26"
 && $"myid" === 120026015).show
```

### Java

```
SparkSession sparkSession =
SparkSession.builder().getOrCreate();
MapRDBJavaSession mapRDBJavaSession =
new MapRDBJavaSession(sparkSession);
Dataset<Row> df2 =
mapRDBJavaSession.lookupFromMapRDB("/tbl");
df2.filter("mydate = '2012-03-26' and
myid = '120026015'").show();
```

### Python

```
from pyspark.sql import SparkSession
df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate = '2012-03-26' and
myid = '120026015'").show()
```

## Loading Data into a DataFrame Using an Explicit Schema

If you know the schema of your data, you can specify an explicit schema when loading a DataFrame.

The following example loads data into a user profile table using an explicit schema:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val addressSchema =
StructType(StructField("Pin",
IntegerType) ::

StructField("city", StringType) ::

StructField("street", StringType) ::
Nil)

val personSchema =
StructType(StructField("_id",
StringType) ::

StructField("first_name",
StringType) ::

StructField("last_name",
StringType) ::

StructField("address",
addressSchema) ::

StructField("interests",
ArrayType(StringType)) :: Nil)

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

StructField[] addressSchema = {
 new
StructField("Pin", IntegerType, true,
Metadata.empty()),
 new
StructField("city",StringType, true,
Metadata.empty()),
 new
StructField("street", StringType,
true, Metadata.empty())
};

StructField[] schemaFields = {
 new StructField("_id", StringType,
true, Metadata.empty()),
 new StructField("first_name",
StringType, true, Metadata.empty()),
 new StructField("address", new
StructType(addressSchema), true,
Metadata.empty()),
 new StructField("interests", new
ArrayType(StringType, true), true,
```

```

Metadata.empty()
 };
StructType personSchema = new
StructType(schemaFields);
MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles", personSchema);

```

## Python

```

from pyspark.sql import SparkSession

addressSchema = [StructField("Pin",
IntegerType(), True),
 StructField("city",
StringType(), True),

StructField("street", StringType(),
True)]
schemaFields = [StructField("_id",
StringType(), True),

StructField("first_name",
StringType(), True),

StructField("last_name",
StringType(), True),

StructField("address",
StructType(addressSchema), True),

StructField("interests",
ArrayType(StringType()), True)]
personSchema =
StructType(schemaFields)

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles", personSchema)

```

To create the DataFrame object named `df`, pass the schema as a parameter to the load call. Invoke the `loadFromMapRDB` method on a `SparkSession` object.

The resulting schema of the object is the following:

```

df.printSchema()

root
|-- _id: String (nullable = true)
|-- first_name: String (nullable = true)
|-- last_name: String (nullable = true)
|-- address: Struct (nullable = true)
| |-- Pin: integer (nullable = true)
| |-- city: string (nullable = true)
| |-- street: string (nullable = true)
|-- interests: array (nullable = true)
| |-- element: string (containsNull = true)

```

When specifying `StructField` in a schema, optionally specify whether the field is nullable. In the example above, all fields are nullable.

Depending on the nullability of the field in the schema and the existence of fields in the HPE Ezmeral Data Fabric Database table, the load returns an `InvalidSchema` exception in the following cases:

- The schema contains a non-nullable field and the load attempts to put a NULL value into the field.
- The schema contains a non-nullable field and the field does not exist in the HPE Ezmeral Data Fabric Database table.
- The HPE Ezmeral Data Fabric Database table has fields that do not exist in the specified schema.

### Loading Data into a DataFrame Using a Type Parameter

If the structure of your data maps to a class in your application, you can specify a type parameter when loading into a DataFrame.

Specify the application class as the type parameter in the load call. The load infers the schema from the class.

The following example creates a DataFrame with a `Person` schema by passing the `Person` class as the type parameter in the load call:

#### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

 case class Person(_id:
String,
 First_name: String,
 last_name: String,
 Address: Address,
 Interests: Seq[String])

val df
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles")
```

#### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

public static class Address
implements Serializable {
 private Integer pin;
 private String street;
 private String city;

 public Integer getPin() { return
pin; }
 public void setPin(Integer pin)
{ this.pin = pin; }
 public String getStreet()
{ return street; }
 public void setStreet(String
street) { this.street = street; }
 public String getCity() { return
city; }
```

```

 public void setCity(String city)
 { this.city = city; }
 }
 public static class Person implements
 Serializable {
 private String _id;
 private String firstName;
 private String lastName;
 private Date dob;
 private Seq<String> interests;

 public String get_id() { return
 _id; }
 public void set_id(String _id)
 { this._id = _id; }
 public String getFirstName()
 { return firstName; }
 public void setFirstName(String
 firstName) { this.firstName =
 firstName; }
 public String getLastName()
 { return lastName; }
 public void setLastName(String
 lastName) { this.lastName =
 lastName; }
 public Date getDob() { return
 dob; }
 public void setDob(Date dob)
 { this.dob = dob; }
 public Seq<String>
 getInterests() { return interests; }
 public void
 setInterests(Seq<String> interests)
 { this.interests = interests; }
 }
 MapRDBJavaSession maprSession = new
 MapRDBJavaSession(sparkSession);
 Dataset<Row> df =
 maprSession.loadFromMapRDB(tableName,
 Person.class);

```

You must invoke the `loadFromMapRDB` method on a `SparkSession` or `MapRDBJavaSession` object.

All fields in an application bean class are nullable by default. The only circumstance in which the load returns an `InvalidSchema` exception is if the HPE Ezmeral Data Fabric Database table contains fields not included in the bean class.

The resulting schema of the object is as follows:

```

df.printSchema()

root
|-- _id: String (nullable = true)
|-- first_name: String (nullable = true)
|-- last_name: String (nullable = true)
|-- address: Struct (nullable = true)
| |-- Pin: integer (nullable = true)
| |-- street: string (nullable = true)
| |-- city: string (nullable = true)
|-- interests: array (nullable = true)
| |-- element: string (containsNull = true)

```

## Loading Data into a DataFrame Using Schema Inference

If you do not know the schema of the data, you can use schema inference to load data into a DataFrame. This section describes how to use schema inference and restrictions that apply

When you do not specify a schema or a type when loading data, schema inference triggers automatically. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark internally samples documents from the HPE Ezmeral Data Fabric Database JSON table and determines a schema based on that data sample. By default, the sample size is 1000 documents. Alternatively, you can specify a sample size parameter. The parameter is optional in the `loadFromMapRDB` call and is named `sampleSize`. The following example specifies using a sample size of 100 documents:

### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df =
sparkSession.loadFromMapRDB(tableName,
sampleSize : 100)
```

### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB(tableName,
100);
```

### Python

```
from pyspark.sql import SparkSession

df = spark.loadFromMapRDB(table_name,
100)
```

**Important:** Because schema inference relies on data sampling, it is non-deterministic. It is not well suited for production use where you need predictable results. Inferring schema results in reading sample rows from the table, hence execution time varies with number of rows in the source table.

## Sampling Using Reader Functions

An alternative to sampling data using the `loadFromMapRDB` call is to use reader functions.

To use the DataFrame reader function (for Scala only), call the following methods:

```
val df = sparkSession.read.maprdb(tableName)
```

To use the reader function with basic Spark, call the `read` function on a `SQLContext` object as follows:

### Scala

```
import org.apache.spark.sql.SQLContext

val df =
sqlContext.read.format("com.mapr.db.sp
ark.sql")
.option("tableName",
```

```
<table-name>
 .option("sampleSize",
100).load()
```

**Java**

```
import
org.apache.spark.sql.SQLContext;

Dataset<Row> df = sqlContext.read()
 .format("com.mapr.db
.spark.sql")
 .option("tableName",
<table-name>).load();
```

**Python**

```
from pyspark.sql import SQLContext

df = sql_context.read\
 .format("com.mapr.db.spark.sql.De
faultSource")\
 .option("tableName",
<table-name>).load()
```

**Type Conflict Resolution When Sampling**

When sampling data during schema inference, you might encounter conflicting value types within a field. The connector uses the following rules to resolve type conflicts:

- If the two conflicting types are each one of the following, the resolved type is the wider of the two types:
  - `ByteType`
  - `ShortType`
  - `IntegerType`
  - `LongType`
  - `FloatType`
  - `DoubleType`

The type list above is arranged in increasing order of width. For example, if one document contains a field of type `ByteType` and the other contains a field of type `FloatType`, the resultant type is `FloatType`.

- If one of the types is `DecimalType`, then the resultant type is `DecimalType`, if and only if `DecimalType` is the wider of the two types.
- If the two types are `StructType`, each with different fields, then the resultant type is a new `StructType` that contains all the fields in each `StructType`.
- If the two types are `ArrayType`, each with different element types, then the resultant type is a new `ArrayType` where the type of the elements in the array is resolved using the aforementioned rules.
- If none of the above rules can be used for resolving type conflicts, then during data conversion, the load reports a `ConflictType` exception.

Suppose `Name` contains `String` values in some rows and a map with `first_name` and `last_name` as nested fields in other rows. During schema inference, the conflict resolution logic encounters two different types for the same field, `StringType` and `MapType`. It will note the conflict and return a `ConflictType` exception later when converting the data during the load.

By default, conflict exceptions occur during data conversion. To change this so that the exception is returned during the conflict resolution stage, set the `FailOnConflict` option to `true` :

#### Scala

```
val df =
 spark.read.maprdb(<tableName>,
 Map("sampleSize" -> 100,
 "FailOnConflict" -> true))
```

### Invalid Schemas

When using schema inference, missing and extra fields are resolved in the following ways:

- If a field in the inferred schema is missing in the HPE Ezmeral Data Fabric Database JSON document, the field is set to null.
- If there are fields in a HPE Ezmeral Data Fabric Database JSON document that are not in the inferred schema, the load returns an `InvalidSchema` exception.

### Type Mapping Between HPE Ezmeral Data Fabric Database JSON and DataFrames

This table maps data types between HPE Ezmeral Data Fabric Database JSON OJAI and Apache Spark DataFrame.

**Note:** Not all DataFrame data types are supported by HPE Ezmeral Data Fabric Database, for a list of supported data types, see [JSON Documents](#) on page 470.

| OJAI Data Type | DataFrame Data Type  |
|----------------|----------------------|
| Boolean        | BooleanType          |
| String         | StringType           |
| Byte           | ByteType             |
| Short          | ShortType            |
| Int            | IntegerType          |
| Long           | LongType             |
| Float          | FloatType            |
| Double         | DoubleType           |
| Decimal        | DecimalType          |
| Date           | DateType             |
| Time           | TimestampType        |
| TimeStamp      | TimeStampType        |
| Interval       | CalendarIntervalType |
| Binary         | BinaryType           |
| Map            | StructType           |
| Array          | ArrayType            |

**Note:** The OJAI `Time` data type is converted to a Spark `TimestampType` with the date set to the epoch date. Spark SQL does not support a `TIME` type.

### Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark Dataset

You can use one of three ways to load data from HPE Ezmeral Data Fabric Database into an Apache Spark Dataset:

- Load the data into a Dataset.
- Load the data into a DataFrame, and then convert it to a Dataset.
- Load the data into a Dataset using a custom encoder.

#### Load into a Dataset

##### Scala

For loading as a Dataset, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](table: String,
 schema : StructType).as [T]: Dataset

import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles").as [T]: Dataset
```

##### Java

For loading as a Dataset, apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB[T <:
 java.lang.Object](tableName: String,
 schema: StructType, sampleSize:
 Double, clazz: Class[T]): Dataset[T]

import
 com.mapr.db.spark.sql.api.java.MapRDBJavaSession;

MapRDBJavaSession maprSession = new
 MapRDBJavaSession(sparkSession);

Dataset<Row> ds =
 maprSession.loadFromMapRDB("/tmp/
 user_profiles");
```

**Note:** The only required parameter to the methods is `tableName`. All the others are optional.

#### Load into DataFrame and Convert to Dataset

To load the data as a DataFrame, see [Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark DataFrame](#) on page 4290. To convert the DataFrame to a Dataset, use the `as[<type>]` method. The `<type>` can be any of the basic types in Scala.

The following code example creates a `Dataset[Person]` using the `as[<type>]` method:

##### Scala

```
import
 org.apache.spark.sql.SparkSession
```

**Java**

```
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

case class Person (_id:String,
first_name:String,
last_name: String, dob:
java.sql.Date,
Interests: Seq[String,
address: Address)

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
```

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

public static class Address
implements Serializable {
private Integer pin;
private String street;
private String city;

public Integer getPin() { return
pin; }
public void setPin(Integer pin)
{ this.pin = pin; }
public String getStreet()
{ return street; }
public void setStreet(String
street) { this.street = street; }
public String getCity() { return
city; }
public void setCity(String city)
{ this.city = city; }
}

public static class Person implements
Serializable {
private String _id;
private String firstName;
private String lastName;
private Date dob;
private Seq<String> interests;
public String get_id()
{ return _id; }
public void
set_id(String _id) { this._id = _id; }
public String
getFirstName() { return firstName; }
public void
setFirstName(String firstName)
{ this.firstName = firstName; }
public String
getLastName() { return lastName; }
public void
setLastName(String lastName)
{ this.lastName = lastName; }
```

```

 public Date getDob()
 { return dob; }
 public void setDob(Date
dob) { this.dob = dob; }
 public Seq<String>
getInterests() { return interests; }
 public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
 }
 Dataset<Person> ds =
 maprSession.loadFromMapRDB(tableName,
 Person.class);

```

### Load into Dataset Using Custom Encoder

You can create a custom encoder for Java bean classes by calling the `Encoders.bean` method.

`Encoders.bean` only support Java classes. To create a `Dataset` of the Scala class, the previous code can be used. The following example shows how to load into a `Dataset` by creating a custom encoder for a Java class named `beanClass`:

#### Scala

```

import
org.apache.spark.sql.SparkSession

import com.mapr.db.spark.sql._

val ds =
sparkSession.loadFromMapRDB("/tmp/
user_profiles")
 .as(Encoders.bean(beanClass))

```

#### Java

```

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(beanC
lass));

```

### Filter Pushdown

After you have loaded data into a `Dataset`, you can apply filter pushdowns. The following example filters on `first_name`:

#### Scala

```
ds.filter($"first_name" === "David")
```

#### Java

```
ds.filter(col("first_name").equalTo("D
avid")).show();
```

See [Projection and Filter Pushdown with Apache Spark DataFrames and Datasets](#) on page 4302 for other examples.

Projection and Filter Pushdown with Apache Spark DataFrames and Datasets

Projection and filter pushdown improve query performance. When you apply the `select` and `filter` methods on DataFrames and Datasets, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark pushes these elements to HPE Ezmeral Data Fabric Database where possible.

### Projection Pushdown

Projection pushdown minimizes data transfer between HPE Ezmeral Data Fabric Database and the Apache Spark engine by omitting unnecessary fields from table scans. It is especially beneficial when a table contains many columns.

When you invoke the following `select` method on a DataFrame, the connector pushes the projection:

#### Scala

```
import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

#### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.select("_id", "first_name",
"last_name");
```

#### Python

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

The equivalent example using Datasets is as follows:

#### Scala

```
import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.select("_id", "first_name",
"last_name")
```

#### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
```

```
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles", Person.class);
ds.select("_id", "first_name",
"last_name");
```

### Filter Pushdown

Filter pushdown improves performance by reducing the amount of data passed between HPE Ezmeral Data Fabric Database and the Apache Spark engine when filtering data.

Consider the following example:

#### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

#### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.filter("first_name = 'Bill'")
```

#### Python

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark pushes the filter `firstName = 'Bill'` down to HPE Ezmeral Data Fabric Database.

The equivalent example using Datasets is as follows:

#### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
```

```
("/tmp/user_profiles").as[Person]
ds.filter($"first_name" === "Bill")
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

Dataset ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(Perso
n.getClass()));
ds.filter(col("first_name").equalTo("B
ill"));
```

The following DataFrame filters those rows in which first\_name is either "David" or "Peter":

**Scala**

```
df.filter($"first_name" === "David"
|| $"first_name" === "Peter")
```

**Java**

```
df.filter(col("first_name").equalTo("D
avid").or(col("first_name").equalTo("P
eter")))
```

**Python**

```
df.filter((col("first_name") ==
"David") | (col("first_name") ==
"Peter"))
```

The following DataFrame retrieves only the rows in which the first\_name is "David" and the last\_name is "Jones":

**Scala**

```
df.filter($"first_name" === "David"
&& $"last_name" === "Jones")
```

**Java**

```
df.filter(col("first_name").equalTo("D
avid").and(col("last_name").equalTo("J
ones")))
```

**Python**

```
df.filter((col("first_name") ==
"David") & (col("last_name") ==
"Jones"))
```

The following uses a not condition to return rows where the first\_name is not "David" and the last\_name is not "Peter":

**Scala**

```
df.filter(not($"first_name" ===
"David" || $"last_name" === "Peter"))
```

**Java**

```
df.filter(not(col("first_name").equalTo("David").or(col("last_name").equalTo("Peter"))))
```

**Python**

```
df.filter(~((col("first_name") == "David") | (col("last_name") == "Peter")))
```

The HPE Ezmeral Data Fabric Database OJAI Connector pushes down all of the filters shown in the earlier examples. It can push down the following types of filters, provided that the field is not an `Array` or `Map`:

- Equal To (=)
- Not Equal To (!=)
- Less Than (<)
- Less Than or Equal To (<=)
- Greater Than (>)
- Greater Than or Equal To (>=)
- In Predicate (IN)
- Like predicate (LIKE)
- AND, OR
- NOT

**Restrictions**

Pushdowns with DataFrames and Datasets are not supported in the following scenarios:

- Filters on complex types, including arrays, maps, and structs

For example, a filter on a field in a map, as shown in the following example, is not pushed down:

**Scala**

```
df.filter($"address.city" === "Milpitas")
```

**Java**

```
df.filter(col("address.city").equalTo("Milpitas"));
```

**Python**

```
df.filter(col("address.city") == "Milpitas")
```

- Filters with functions `sizeof`, `typeof`, and `matches`  
Spark SQL does not support these functions.
- Projections on complex types, including arrays, maps, and structs

For example, if you select an element of an array, as shown in the following example, it is not pushed down:

**Scala**

```
ds.select($"hobbies" (0))
```

**Java**

```
df.select(col("hobbies").getItem(0));
```

**Python**

```
df.select(col("hobbies").getItem(0))
```

These limitations do not apply to pushdowns on RDDs. An alternative is to apply the [pushdown using an RDD](#), and then [convert the RDD to a DataFrame](#).

**Note:** HPE Ezmeral Data Fabric Database 6.0 introduces support for [Secondary Indexes](#) on page 506, but the HPE Ezmeral Data Fabric Database OJAI Connector for Spark does not currently leverage them.

### Converting an Apache Spark RDD to an Apache Spark DataFrame

When APIs are only available on an Apache Spark RDD but not an Apache Spark DataFrame, you can operate on the RDD and then convert it to a DataFrame.

You can convert an RDD to a DataFrame in one of two ways:

- Use the helper function, `toDF`.
- Convert the RDD to a DataFrame using the `createDataFrame` call on a `SparkSession` object.

#### Using the `toDF` Helper Function

The `toDF` method is available through `MapRDBTableScanRDD`. The following example loads an RDD that filters on `first_name` equal to "Peter" and projects the `_id` and `first_name` fields, and then converts the RDD to a DataFrame:

**Scala**

```
import com.mapr.db.spark.sql._

val df =
 sc.loadFromMapRDB(<table-name>)
 .where(field("first_name")
 === "Peter")
 .select("_id",
 "first_name").toDF()
```

#### Using `SparkSession.createDataFrame`

With this approach, you can convert an `RDD[Row]` to a `DataFrame` by calling `createDataFrame` on a `SparkSession` object. The API for the call is as follows:

**Scala**

```
def createDataFrame(RDD, schema:
 StructType)
```

You might need to first convert an `RDD[OJAIDocument]` to an `RDD[Row]`. The following example shows how to do this:

**Scala**

```
val df = sparkSession.createDataFrame(
 rdd.map(doc
=>MapRDBSpark.docToRow(doc, schema)),
 schema)
```

`rdd` is of type `RDD[OJAIDocument]`. The `docToRow` call converts `rdd` to an `RDD[Row]` that is then passed to `createDataFrame`.

*Working with Complex JSON Document Types*

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides APIs to process JSON documents loaded from HPE Ezmeral Data Fabric Database.

Suppose you want to calculate the number of users located in each city:

**Scala**

```
import com.mapr.db.spark.sql._

val customerprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
val numberOfCustaccCities =
customerprofilesRDD.map(a =>
(a.`address.city`[String],a))
 .groupByKe
y()
 .map(a =>
(a._1, a._2.size))
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import scala.Tuple2;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
JavaRDD numberofCustaccCities =
customerprofilesRDD.mapToPair
(a -> new
Tuple2<>(a.getString("address.city"),
a)).groupByKey()
.map(a -> new Tuple2<>(a._1,
((Collection<?>)a._2).size()));
```

If you have not provided an explicit cast, then the object is returned as `AnyRef`. To access methods specific to a class, such as `String` or `Integer`, you can cast it to a specific type later in the process.

Now suppose you want to collect all the addresses (address is of type `Map`) of all customers:

**Scala**

```
import com.mapr.db.spark.sql._

val customerprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles")
val customersAddress =
```

```
customerprofilesRDD.map(a =>
a.address).collect
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAI Document>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<String> customersAddress =
customerprofilesRDD.map(a ->
a.getString("address")).collect();
```

customersAddress contains all of the addresses, but is returned as an AnyRef object.

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark introduces three new classes to wrap complex JSON types:

| Class         | Type                |
|---------------|---------------------|
| DBMapValue    | Map[String, AnyRef] |
| DBArrayValue  | Array[AnyRef]       |
| DBBinaryValue | ByteBuffer          |

These classes are not exposed; however, you can access the underlying elements of DBArrayValue and DBMapValue by using the same functions as in Seq and Map. DBArrayValue works like a sequence, while DBMapValue works like a map.

DBBinaryValue is a class wrapper around ByteBuffer. ByteBuffer is not serializable, so you will get serialization errors if you use the ByteBuffer in Spark code. You must ensure that byte buffers are converted to DBBinaryValue or serialized byte buffers. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides an API to convert ByteBuffers to serializable byte buffers.

**Accessing Values in a Map**

DBMapValue is a type of Map[String, AnyRef]. Any functions that you can use to access values in the Map, you can also use to access values in DBMapValue. In the following example, customeraddress contains the address of the customers who reside in San Jose. customeraddress is an Array[DBMapValue]:

**Scala**

```
val customerAddress = maprd.map(a =>
a.address[Map[String, AnyRef]])
 .filter(a => a!= null &&
a.get("city").contains("San Jose"))
 .collect
```

This example can also be written in Scala using a functional approach as follows:

**Scala**

```
val customerAddress = maprd.map(a
=> (a.address[Map[String, AnyRef]],
a).join(my_documents)
 .filter(a =>
```

```
Option(a).map(a =>
a.get("city").contains("San
Jose")).getOrElse(false))
.collect
```

**Note:** You can push the condition specified in the filter condition to the HPE Ezmeral Data Fabric Database table scan by using the `where` clause.

### Accessing the Array JSON Object

This example uses a sequence to access the Array JSON object:

#### Scala

```
val custInterests = maprd.map(a =>
a.interests[Seq[AnyRef]])
 .filter(a => a !=
null && a(0) == "sports")
 .collect
```

### ByteBuffer Serialization

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to enable serialization of the `ByteBuffer`:

#### Scala

```
MapRDBSpark.serializableBinaryValue(byteBuffer)
```

The following example shows an array of byte buffers or binary values that are converted to serialized byte buffers by using `MapRDBSpark.serializableBinaryValue`:

#### Scala

```
val dstSplits =
arrayOfByteBuffer.map(x =>
MapRDBSpark.serializableBinaryValue(x)
)
```

#### *Saving Data to a HPE Ezmeral Data Fabric Database JSON Table*

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides an API to save an Apache Spark RDD to a HPE Ezmeral Data Fabric Database JSON table. Starting in the EEP 4.0 release, the connector introduces support for saving Apache Spark DataFrames and DStreams to HPE Ezmeral Data Fabric Database JSON tables.

Saving an Apache Spark RDD to a HPE Ezmeral Data Fabric Database JSON Table

### Saving an RDD[OJAIDocument] to HPE Ezmeral Data Fabric Database

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to save an `RDD[OJAIDocument]` to a HPE Ezmeral Data Fabric Database table:

#### Scala

For saving an RDD, apply the following method on the RDD:

```
def saveToMapRDB(tablename: String,
createTable: Boolean =
false, bulkInsert: Boolean =
```

```
false, idFieldPath: String =
DocumentConstants.ID_KEY) : Unit
```

## Java

For saving an RDD, apply one of the following methods on a `MapRDBJavaSparkContext` object:

```
def saveToMapRDB[D](javaRDD:
JavaRDD[D], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveRowRDDToMapRDB(javaRDD:
JavaRDD[Row], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveToMapRDB[K, V <: AnyRef]
(javaPairRDD: JavaPairRDD[K, V],
keyClazz: Class[K], valueClazz:
Class[V], tableName: String,
createTable: Boolean, bulkInsert:
Boolean): Unit
```

**Note:** The only required parameter to the methods is `tableName`. All the others are optional.

In the following example, `address` and `first_name` data is loaded from the `"/tmp/user_profiles"` table, stored as an RDD (`userprofilesRDD`), and then saved to the `"/tmp/user_firstname_and_address"` table:

## Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")

 .where("condition
")
 .select("address"
, "first_name")

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address")
```

## Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
 .where("condition")
 .select("address",
"first_name");
```

```
mapRDBSparkContext.saveToMapRDB(userprofilesRDD, "/tmp/
user_firstname_and_address", true,
false, "_id");
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert an RDD[OJAIDocument] to a HPE Ezmeral Data Fabric Database table:

 **Note:** The insertToMapRDB API is available starting in the EEP 4.1.0 release.

#### Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
userprofilesRDD.insertToMapRDB(tablename, createTable = true, bulkInsert =
false, idFieldPath = "_id")
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaSparkContext;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
MapRDBJavaRDD<OJAIDocument>
userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles");
mapRDBSparkContext.insertRowRDDToMapRDB(userprofilesRDD, tablename);
```

 **Note:** The insertToMapRDB API throws an exception if a row with the same ID already exists.

This API supports the following parameters:

#### Scala

| Parameter   | Default        | Description                                                                                                                                       |
|-------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| tableName   | Not applicable | The name of the HPE Ezmeral Data Fabric Database table in which you are saving the document.                                                      |
| createTable | false          | Creates the table before saving the documents. Note that if the table already exists and createTable is set to true, the API throws an exception. |
| idFieldPath | _id            | Specifies the key to be used for the document.                                                                                                    |

| Parameter  | Default | Description                                                                              |
|------------|---------|------------------------------------------------------------------------------------------|
| bulkInsert | false   | Loads a group of rows simultaneously. bulkInsert is similar to a bulk load in MapReduce. |

## Java

| Parameter                         | Default        | Description                                                                                                                                      |
|-----------------------------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| RDD (JavaRDD or JavaPairRDD)      | Not applicable | Specifies the RDD which you are saving to the HPE Ezmeral Data Fabric Database table.                                                            |
| tableName                         | Not applicable | Specifies the name of the HPE Ezmeral Data Fabric Database table in which you are saving the document.                                           |
| createTable                       | false          | Creates the table before saving the document. Note that if the table already exists and createTable is set to true, the API throws an exception. |
| idFieldPath                       | _id            | Specifies the key to be used for the document.                                                                                                   |
| bulkInsert                        | false          | Loads a group of rows simultaneously. bulkInsert is similar to a bulk load in MapReduce.                                                         |
| keyClazz (Only for JavaPairRDD)   | Not applicable | Specifies the class type which is the key in the JavaPairRDD which you are saving into the HPE Ezmeral Data Fabric Database table.               |
| valueClazz (Only for JavaPairRDD) | Not applicable | Specifies the class type which is the value in the JavaPairRDD which you are saving into the HPE Ezmeral Data Fabric Database table.             |

In Java, `saveToMapRDB` method works with `JavaRDD` and `JavaPairRDD`. For saving `JavaRDD[Row]`, use the `saveRowRDDToMapRDB` method.

The following example specifies a key by using the `idFieldPath` parameter and the `bulkInsert` value to save the RDD:

### Scala

```
import com.mapr.db.spark._

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address",

idFieldPath = "user_id",

bulkInsert = false)
```

### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
```

```
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
mapRDBSparkContext.saveToMapRDB(userprofilesRDD, "/tmp/
user_firstname_and_address", false,
false, "user_id");
```

The following example saves an RDD of `Person` objects into the newly created `/tmp/Userinfo` table:

### Scala

```
import com.mapr.db.spark._

val sparkConf =
new SparkConf().setAppName("json
app").setMaster("local[*]")
val sc = new SparkContext(sparkConf)
val people =
sc.parallelize(getUsers())
people.saveToMapRDB("/tmp/UserInfo",
createTable= true)
```

### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

SparkConf sparkConf = new
SparkConf().setAppName("json
app").setMaster("local[*]");
SparkContext sc = new
SparkContext(sparkConf);
JavaRDD rdd =
sc.parallelize(getUsers());
mapRDBSparkContext.saveToMapRDB(rdd,
"/tmp/UserInfo", true);
```

The following example shows the `getUsers` function that allocates the `Person` objects:

### Scala

```
def getUsers(): Array[Person] = {
 val users: Array[Person] =

 Array(
 Person("DavUSCalif", "David",
"Jones",
 ODate.parse("1947-11-29"),
 Seq("football", "books",
"movies"),
 Map("city" -> "milpitas",
"street" -> "350 holger way",
"Pin" -> 95035)),
 Person("PetUSUtah", "Peter",
"pan",
 ODate.parse("1974-1-29"),
 Seq("boxing", "music",
"movies"),
 Map("city" -> "salt lake",
"street" -> "351 lake way", "Pin" ->
89898)),
```

```

 Person("JamUSAriz", "James",
"junior",
 ODate.parse("1968-10-2"),
 Seq("tennis", "painting",
"music"),
 Map("city" -> "phoenix",
"street" -> "358 pond way", "Pin" ->
67765)),

 Person("JimUSCalif", "Jimmy",
"gill",
 ODate.parse("1976-1-9"),
 Seq("cricket",
"sketching"),
 Map("city" -> "san jose",
"street" -> "305 city way", "Pin" ->
95652)),

 Person("IndUSCalif",
"Indiana", "Jones",
 ODate.parse("1987-5-4"),
 Seq("squash", "comics",
"movies"),
 Map("city" -> "sunnyvale",
"street" -> "35 town way", "Pin" ->
95985)))

 users
}

```

### Saving a JSON Document to HPE Ezmeral Data Fabric Database

To save a JSON document using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must first convert the JSON document into an OJAI document and then save the RDD, as shown in the following example:

#### Scala

```

import com.mapr.db.spark._

val documents = sc.parallelize((1 to
10)
 .map(i => s""{"_id":
"$i", "test": "$i}""))
val maprd = documents.map(a =>
MapRDBSpark.newDocument(a))
maprd.saveToMapRDB("/tmp/testData")

```

#### Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.api.java.JavaSparkCon
text;

JavaRDD<String> documents =
JavaSparkContext.fromSparkContext(sc)
 .parallelize(Arrays.asList
(1, 2, 3, 4, 5, 6, 7, 8, 9, 10))
 .map(i -> { return

```

```

"{\"id\": \"\" + i + "\", \"test\":
\"\" + i + "\"}"; });
JavaRDD<OJAI Document> maprd =
documents.map(MapRDBSpark::newDocument
);
mapRDBSparkContext.saveToMapRDB(maprd,
"/tmp/testData");

```

An `_id` field is required to save JSON data into a table, so an `_id` field must be present. If you need only to convert the JSON data to an OJAI document (without saving to HPE Ezmeral Data Fabric Database), the `_id` field is not required. If the HPE Ezmeral Data Fabric Database table already contains a record with the same `_id` value, HPE Ezmeral Data Fabric Database replaces the record. Otherwise, it inserts a new record.

Just as you can load a JSON document into a Scala bean class (see [Creating an RDD of a Class](#)), you can save the RDD of Scala class objects in a HPE Ezmeral Data Fabric Database JSON table. `saveToMapRDB` can save any bean object as a JSON document by converting it to a JSON document.

### Table Splits and `saveToMapRDB`

If the `createTable` parameter is set to `true`, `saveToMapRDB` can use the partition information from the RDD's lineage to create the splits for a new table:

#### Scala

```

sc.loadFromMapRDB("/tmp/
user_profiles").saveToMapRDB("/
userProfiles",

createTable = true)

```

Suppose `/tmp/user_profiles` has a table with five splits. `saveToMapRDB` uses this information to create the `/userProfiles` table with the same number and range of splits. You can also supply this information by using `MapRDBSpark.newPartitioner`:

#### Scala

```

sc.loadFromMapRDB("/tmp/
user_profiles").keyBy(doc =>
doc.get("_id"))
.repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String]
("/profiles"))
.saveToMapRDB("/userProfiles",
createTable = true)

```

For more information about partitioning, see [Using the Custom Partitioner with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark](#) on page 4288.

### Saving an Apache Spark DataFrame to a HPE Ezmeral Data Fabric Database JSON Table

To save an Apache Spark DataFrame to a HPE Ezmeral Data Fabric Database, invoke the `saveToMapRDB` method on the `DataFrame` object (Scala). This returns a `DataFrameWriter` object, from which you can invoke the `saveToMapRDB` method. For Java and Python, invoke the `saveToMapRDB` method on the `MapRDBJavaSession` object or `SparkSession` object, respectively.

If a row with the same ID already exists, the `saveToMapRDB` method updates or overwrites that row. If you want an exception to be thrown in this case, you can use the [insertToMapRDB](#) method.

**Scala**

```
import com.mapr.db.spark.sql._

df.write.saveToMapRDB("/tmp/userInfo")
```

For EEP 4.1.0 and later, you can directly invoke the `saveToMapRDB` method on the `DataFrame` object:

```
def saveToMapRDB(tableName: String,
 idFieldPath : String = "_id",
 createTable: Boolean = false,
 bulkInsert: Boolean = false): Unit

import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

val df = spark.loadFromMapRDB("/tmp/
user_profiles")
df.saveToMapRDB(tableName,
createTable = true)
```

**Java**

For saving a `DataFrame (Dataset<Row>)`, apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](df: DataFrame[T],
 tableName: String, idFieldPath:
String, createTable: Boolean,
bulkInsert: Boolean): Unit

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");

maprSession.saveToMapRDB(ds, "/tmp/
userInfo");
```

**Python**

For saving a `DataFrame`, apply the following method on a `Dataframe`:

```
def saveToMapRDB(dataframe,
 table_name, id_field_path =
default_id_field, create_table =
False, bulk_insert = False)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")

sparkSession.saveToMapRDB(df,
table_name, create_table=True)
```

Inserting an Apache Spark `DataFrame` into a HPE Ezmeral Data Fabric Database JSON Table

Starting in the EEP 4.1.0 release, you can use the `insertToMapRDB` API to insert an Apache Spark DataFrame into a MapR Database JSON table in Python. The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

PySpark supports only `DataFrame(Dataset<Row>)`:

#### Python

```
sparkSession.insertToMapRDB(df,
 tableName, idFieldPath, bulkInsert)
```

### Using Alternate Write Modes for HPE Ezmeral Data Fabric Database OJAI Connector

You can use alternate write modes supported by MapR Database OJAI Connector for Apache Spark to save an Apache Spark DataFrame to a MapR Database JSON table.

Normally, the Apache Spark `DataFrameWriter` class supports the following write modes:

- Append
- Overwrite
- ErrorIfExists
- Ignore

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark returns an `OperationNotSupported` exception if you attempt to use one of these modes. The following example returns the error:

#### Scala

```
import org.apache.spark.sql.SaveMode
import com.mapr.db.spark.sql._

df.write.mode(SaveMode.Append).saveToMapRDB("/tmp/userInfo")
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following alternative modes:

|                        |                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Insert</b>          | Inserts the data into the HPE Ezmeral Data Fabric Database table. Throws a <code>DBException</code> if a row with same <code>_id</code> value already exists in the table. |
| <b>Overwrite</b>       | Overwrites the data in the table with the current DataFrame data. This operation drops the table and creates a new table with the data.                                    |
| <b>ErrorIfExists</b>   | Returns an exception ( <code>TableExistsException</code> ) if the table already exists. Otherwise, creates the table and inserts the data.                                 |
| <b>Ignore</b>          | Ignores the data in the table if the table already exists. Otherwise, creates the table and inserts the data.                                                              |
| <b>InsertOrReplace</b> | Replaces the row with the row in the DataFrame, if a row with the same <code>_id</code> already exists in the table. Otherwise, inserts the new row.                       |

You cannot specify these modes using the Apache Spark `SaveMode` method. Doing so results in the same `OperationNotSupported` exception noted earlier. To use these modes, you must call the `option` method on a `DataFrameWriter` object. The following example sets the `Insert` mode:

**Scala**

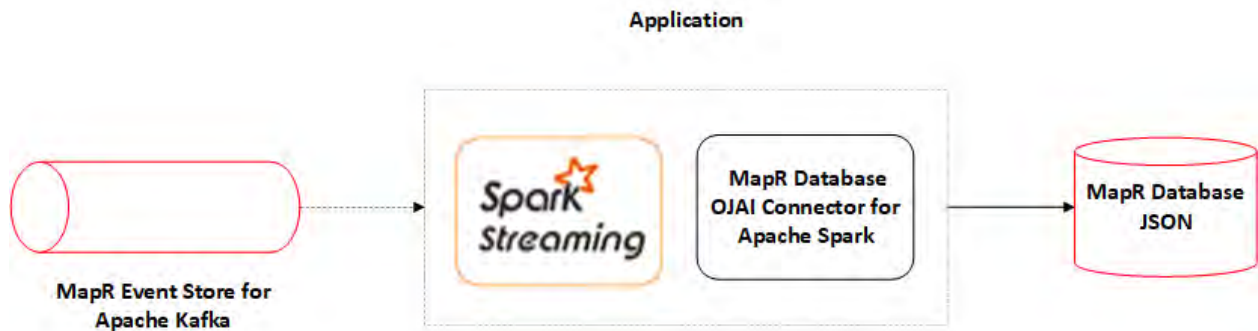

```
df.write.option("Operation",
 "Insert").saveToMapRDB("/tmp/
 usersInfo")
```

**Note:** The UPDATE mode for HPE Ezmeral Data Fabric Database OJAI Connector is not supported and it results in an `OperationNotSupported` exception.

## Saving an Apache Spark DStream to a HPE Ezmeral Data Fabric Database JSON Table

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark enables you to use HPE Ezmeral Data Fabric Database as a sink for Apache Spark DStreams.

**Note:** Saving of Apache Spark DStream to HPE Ezmeral Data Fabric Database JSON table is currently only supported in Scala.

The following API saves a `DStream[OJAIDocument]` object to a HPE Ezmeral Data Fabric Database table:

**Scala**

```
def saveToMapRDB(tablename: String,
 createTable: Boolean,
 bulkInsert: Boolean,
 idFieldPath: String): Unit
```

The parameters are as follows:

| Parameter   | Default          | Description                                                                                                                                                  |
|-------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tableName   | Not applicable   | The name of the HPE Ezmeral Data Fabric Database table to which you are saving the DStream.                                                                  |
| createTable | false            | Creates the table before saving the DStream. Note that if the table already exists and <code>createTable</code> is set to true, the API throws an exception. |
| idFieldPath | <code>_id</code> | Specifies the key to be used for the DStream.                                                                                                                |
| bulkInsert  | false            | Loads a group of streams simultaneously. <code>bulkInsert</code> is similar to a bulk load in MapReduce.                                                     |

**Note:** The only required parameter for this function is `tableName`. All the others are optional.

The following example creates a DStream object, converts it to a `DStream[OJAIDocument]` object, and then stores it in HPE Ezmeral Data Fabric Database:

**Scala**

```
val clicksStream: DStream[String] =
 createKafkaStream(...)
```

```
clicksStream.map(MapRDBSpark.newDocument())
 .saveToMapRDB("/clicks",
 createTable=true)
```

 **Note:** You must use the `map(MapRDBSpark.newDocument())` API to convert the `DStream` object to a `DStream[OJAI Document]` object.

If `clicksStream` is a `DStream` of `Strings`, it can be saved to HPE Ezmeral Data Fabric Database using the `saveToMapRDB` API:

#### Scala

```
clicksStream.map(MapRDBSpark.newDocument(_))
 .saveToMapRDB("/clicks",
 createTable = true);
```

 **Note:** To use the `saveToMapRDB` API, you need to transform the `DStream` object to a `DStream[OJAI Document]` by using the Apache Spark Map API.

### Saving an Apache Spark Dataset to a HPE Ezmeral Data Fabric Database JSON Table

Starting in the EEP 4.1.0 release, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to save a Dataset to a HPE Ezmeral Data Fabric Database table:

#### Scala

For saving a Dataset, apply the following method on a Spark object:

```
def saveToMapRDB(tableName: String,
 idFieldPath : String = "_id",
 createTable: Boolean =
 false, bulkInsert:Boolean = false):
 Unit

import
 org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds = spark.loadFromMapRDB("/tmp/
 user_profiles")
ds.saveToMapRDB(tableName,
 createTable = true)
```

#### Java

For saving a Dataset, apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](ds: Dataset[T],
 tableName: String, idFieldPath:
 String,
 createTable: Boolean,
 bulkInsert: Boolean): Unit

import
 com.mapr.db.spark.sql.api.java.MapRDBJavaSession;
import
 org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
 MapRDBJavaSession(spark);
Dataset<Row> ds =
```

```
maprSession.loadFromMapRDB("/tmp/
user_profiles");
maprSession.saveToMapRDB(ds, true);
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert a Dataset into a HPE Ezmeral Data Fabric Database table:

#### Scala

```
import com.mapr.db.spark._

ds.insertToMapRDB(tableName,
idFieldPath, bulkInsert)
```

#### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.insertToMapRDB(ds,
tableName, idFieldPath, bulkInsert)
```

**Note:** The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

### Word Count Example Using HPE Ezmeral Data Fabric Database OJAI Connector

 println(usage)
 }

 private def
importDataIntoSeq(filePath: String):
Seq[Word] = {
 scala.io.Source.fromURL(filePath)
 .getLines
 .map(line => {
 val wordWithId = line.split("
")
 Word(wordWithId(0),
wordWithId.drop(1).mkString(" "))
 }).toSeq
 }

 private case class Word(_id:
String, words: String)
}

```

### *Using Serialization with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark*

In the context of the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, serialization refers to the methods that read and write objects into bytes. This section describes how to configure your application to use a more efficient serializer.

The Apache Spark cluster framework requires serialization to exchange objects between driver and cluster executors. This type of serialization has nothing to do with the way HPE Ezmeral Data Fabric Database serializes the objects onto the disk.

Because classes used in Spark transformations or actions must be serializable, classes created for the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark are serializable.

Spark uses Java serialization by default, but it can alternatively use Kyro Serialization. A new Kyro registrator is introduced so you can avoid using the default Java serialization. Kyro serialization provides better performance than Java serialization.

The following example shows how to set the new Kyro registrator in `sparkconf`:

#### **Scala**

```

new sparkconf()
 .set("spark.serializer",
"org.apache.spark.serializer.KryoSeria
lizer")
 .set("spark.kryo.registrator",

```

```
"com.mapr.db.spark.OJAIKryoRegistrar
")
```

A JSON document can use both complex and primitive value types. Java can serialize the primitive types, but for complex types (such as `Map`, `Array`, and `Binary`), you must use wrappers to achieve serialization. See [Working with Complex JSON Document Types](#) on page 4308 for details about these wrappers.

Time-related data types, such as `ODate`, `OInterval`, `OTime`, and `OTimeStamp`, use Java serialization by default. For efficiency, new serializers and comparators have been created for these data types.

Here are the new serializers and the type which each serializer applies:

| Serializer                           | Type                    |
|--------------------------------------|-------------------------|
| <code>ODateSerializer</code>         | <code>ODate</code> type |
| <code>OTimeSerializer</code>         | <code>OTime</code>      |
| <code>OTimeStampSerializer</code>    | <code>OTimeStamp</code> |
| <code>OIntervalSerializer</code>     | <code>OInterval</code>  |
| <code>DBBinaryValueSerializer</code> | <code>ByteBuffer</code> |

### HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark

This section describes the three main interaction points between Spark and HBase APIs and provides examples for each interaction point.

The interaction points are:

|                            |                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Basic Spark                | You can have an HBase Connection at any point in your Spark DAG.                                                              |
| Spark Streaming            | You can have an HBase Connection at any point in your Spark Streaming application.                                            |
| Spark Structured Streaming | Using Spark structured streaming to write data to a HPE Ezmeral Data Fabric Database binary table is currently not supported. |
| Spark Bulk Load            | This option is currently not supported for HPE Ezmeral Data Fabric Database.                                                  |
| SparkSQL/DataFrames        | You can write SparkSQL that draws on tables that are represented in HBase.                                                    |

The following pages provide examples of each of these interaction points.

#### *Configuring the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark*

Use these steps to configure the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark:

1. Verify that the `mapr-hbase` package is installed. For more information, refer to the [HBase release notes](#).
2. Copy the `HBASE_HOME/conf/hbase-site.xml` file to `SPARK_HOME/conf/`.
3. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf`:

```
spark.yarn.dist.files SPARK_HOME/conf/hbase-site.xml
```

#### *HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark Integration with Basic Spark*

This page describes integration between Apache Spark and HBase APIs.

This section describes Spark integration with HBase APIs at the lowest and simplest levels. All other interaction points are built upon the concepts described here.

At the root of all integration with Spark and HBase APIs is the `HBaseContext`. The `HBaseContext` takes in HBase configurations and pushes them to the Spark executors. This allows you to have an `HBase Connection` per Spark executor in a static location.

### HBaseContext Usage Example

This example shows how `HBaseContext` can be used to do a `foreachPartition` on an RDD in Scala:

```
val sc = new SparkContext("local", "test")
val config = new HbaseConfiguration()
...
val hbaseContext = new HBaseContext(sc, config)

rdd.hbaseForeachPartition(hbaseContext, (it, conn) => {
 val bufferedMutator = conn.getBufferedMutator(TableName.valueOf("/apps/
my_table"))
 it.foreach((putRecord) => {
 val put = new Put(putRecord._1)
 putRecord._2.foreach((putValue) =>
 put.addColumn(putValue._1,
 putValue._2, putValue._3))
 bufferedMutator.mutate(put)
 })
 bufferedMutator.flush()
 bufferedMutator.close()
})
```

Here is the same example implemented in Java:

```
JavaSparkContext jsc = new JavaSparkContext(sparkConf);

try {
 List<byte[]> list = new ArrayList<>();
 list.add(Bytes.toBytes("1"));
 ...
 list.add(Bytes.toBytes("5"));

 JavaRDD<byte[]> rdd = jsc.parallelize(list);
 Configuration conf = HBaseConfiguration.create();
 JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);

 hbaseContext.foreachPartition(
 rdd,
 new VoidFunction<Tuple2<Iterator<byte[]>, Connection>>() {
 public void call(Tuple2<Iterator<byte[]>, Connection> t) throws
Exception {
 Table table = t._2().getTable(TableName.valueOf(tableName));
 BufferedMutator mutator =
t._2().getBufferedMutator(TableName.valueOf(tableName));
 while (t._1().hasNext()) {
 byte[] b = t._1().next();
 Result r = table.get(new Get(b));
 if (r.getExists()) {
 mutator.mutate(new Put(b));
 }
 }

 mutator.flush();
 mutator.close();
 table.close();
 }
 });
} finally {
 jsc.stop();
}
```

All functionality between Spark and HBase Client is supported both in Scala and in Java, with the exception of SparkSQL, which supports any language that is supported by Spark. This section focuses on Scala examples.

The example here shows how to do a `foreachPartition` with a connection. A number of other Spark base functions are supported out of the box:

|                           |                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------|
| <code>bulkPut</code>      | Enables massively parallel sending of puts to HBase.                                   |
| <code>bulkDelete</code>   | Enables massively parallel sending of deletes to HBase.                                |
| <code>bulkGet</code>      | Enables massively parallel sending of gets to HBase to create a new RDD.               |
| <code>mapPartition</code> | Enables the Spark Map function with a Connection object to allow full access to HBase. |
| <code>hBaseRDD</code>     | Simplifies a distributed scan to create an RDD.                                        |

You can see examples of these commands in the [source code of the HBase-Spark Module](#).

*HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark Integration with Spark Streaming*

[Spark Streaming](#) is a micro-batching, stream-processing framework built on top of Spark. HBase APIs and Spark Streaming make great companions. When used alongside Spark Streaming, HBase APIs can serve as:

- A place to grab reference data or profile data on the fly.
- A place to store counts or aggregates in a way that supports the Spark Streaming promise of only once processing.

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark integration points with Spark Streaming are similar to its normal Spark integration points. You can use the following commands straight off a Spark Streaming DStream:

|                           |                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------|
| <code>bulkPut</code>      | Enables massively parallel sending of puts to HBase APIs.                                   |
| <code>bulkDelete</code>   | Enables massively parallel sending of deletes to HBase APIs.                                |
| <code>bulkGet</code>      | Enables massively parallel sending of gets to HBase APIs to create a new RDD.               |
| <code>mapPartition</code> | Enables the Spark Map function with a Connection object to allow full access to HBase APIs. |
| <code>hBaseRDD</code>     | Simplifies a distributed scan to create an RDD.                                             |

### **bulkPut Example with DStreams**

The following example shows a `bulkPut` with DStreams. It is similar to the RDD bulk put.

**Note:** To invoke the `hbaseBulkPut` method, make sure you import the `HBaseDStreamFunctions` class.

```
import org.apache.hadoop.hbase.spark.HBaseDStreamFunctions._

val sc = new SparkContext("local", "test")
val config = new HBaseConfiguration()

val hbaseContext = new HBaseContext(sc, config)
val ssc = new StreamingContext(sc, Milliseconds(200))

val rdd1 = ...
val rdd2 = ...
val queue = mutable.Queue[
```

```

RDD[(Array[Byte],
 Array[(Array[Byte],
 Array[Byte],
 Array[Byte])])])]()

queue += rdd1
queue += rdd2

val dStream = ssc.queueStream(queue)

dStream.hbaseBulkPut(
 hbaseContext,
 TableName.valueOf(tableName),
 (putRecord) => {
 val put = new Put(putRecord._1)
 putRecord._2.foreach((putValue) =>
 put.addColumn(putValue._1, putValue._2, putValue._3))
 put
 })

```

The `hbaseBulkPut` function has three inputs:

- The `hbaseContext` that carries the configuration broadcast information link to the HBase Connections in the executors.
- The table name of the table you are putting data into.
- A function that will convert a record in the DStream into an HBase `Put` object.

The code snippet above has been extracted from <https://github.com/mapr/hbase/blob/1.1.8-mapr-1703/hbase-spark/src/test/scala/org/apache/hadoop/hbase/spark/HBaseDStreamFunctionsSuite.scala>.

### *Bulk Loading Data into HBase with Spark*

There are two options for bulk loading data into HBase with Spark:

**Note:** The bulk load operation is currently not supported for HPE Ezmeral Data Fabric Database.

#### **Basic bulk load functionality**

The basic bulk load functionality works for cases where your rows have millions of columns and cases where your columns are not consolidated.

#### **Thin-record bulk load option**

The thin-record bulk load option with Spark is designed for tables that have fewer than 10,000 columns per row. The advantage of this option is higher throughput and less overall load on the Spark shuffle operation.

Both implementations work more or less like the MapReduce bulk load process. A partitioner partitions the RowKeys based on region splits, and the RowKeys are sent to the reducers in order, so that HFiles can be written directly from the reduce phase.

In Spark terms, the bulk load is implemented around a `SparkrepartitionAndSortWithinPartitions` followed by a `Spark foreachPartition`. Here is an example of using the basic bulk load functionality:

### **Bulk Loading Example**

**Note:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```

import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,

```

```

TableInputFormat}
import org.apache.hadoop.hbase.spark._
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.util.Bytes._
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.Session
import org.apache.hadoop.hbase.client.{HBaseAdmin, HConnectionManager}
val tableName = "table1"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
@transient val conf = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, conf)
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val rdd = sc.parallelize(Array(
 (toBytes("1"), (toBytes(columnFamily1), toBytes("a"),
toBytes("foo1"))),
 (toBytes("3"), (toBytes(columnFamily1), toBytes("b"),
toBytes("foo2.b"))))
))
rdd.hbaseBulkLoad(hbaseContext,
 TableName.valueOf(tableName),
 t => {
 val rowKey = t._1
 val family: Array[Byte] = t._2._1
 val qualifier = t._2._2
 val value: Array[Byte] = t._2._3
 val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
 Seq((keyFamilyQualifier, value)).iterator
 },
 stagingFolder)
val connection = HConnectionManager.createConnection(conf)
val table = connection.getTable(TableName.valueOf(tableName))
val load = new LoadIncrementalHFiles(conf)
load.doBulkLoad(
 new Path(stagingFolder),
 connection.getAdmin,
 table,
 connection.getRegionLocator(TableName.valueOf(tableName)))

```

### Required Parameters for Bulk Loading with Spark

The `hbaseBulkLoad` function takes three required parameters:

- The name of the table you intend to bulk load to.
- A function that converts a record in the RDD to a tuple key-value pair, with the tuple key being a `KeyFamilyQualifier` object and the value being the cell value. The `KeyFamilyQualifier` object holds the RowKey, Column Family, and Column Qualifier. The shuffle partitions on the RowKey but sorts by all three values.
- The temporary path for the HFile to be written out to. Following the Spark bulk load command, use the `HBase LoadIncrementalHFiles` object to load the newly created HFiles into HBase.

### Additional Parameters for Bulk Loading with Spark

You can set the following attributes with additional parameter options on `hbaseBulkLoad`:

- Max file size of the HFiles

- A flag to exclude HFiles from compactions
- Column Family settings for compression, bloomType, blockSize, and dataBlockEncoding

The following example shows the use of additional parameters:

**Note:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{FamilyHFileWriteOptions,
HBaseContext, KeyFamilyQualifier}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, HConstants, TableName}
import org.apache.spark.sql.SparkSession
 val tableName = "table2"
 val stagingFolder = "/home/mapr"
 val columnFamily1 = "cf1"
 val sc = spark.sparkContext
 @transient val conf = HBaseConfiguration.create()
 conf.set(TableInputFormat.INPUT_TABLE, tableName)
 conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
 conf.setInt("hbase.zookeeper.property.clientPort", 5181)
 val hbaseContext = new HBaseContext(sc, conf)
 val rdd = sc.parallelize(Array(
 (Bytes.toBytes("1"),
 (Bytes.toBytes(columnFamily1),
 Bytes.toBytes("a"), Bytes.toBytes("foo1"))),
 (Bytes.toBytes("3"),
 (Bytes.toBytes(columnFamily1),
 Bytes.toBytes("b"),
 Bytes.toBytes("foo2.b")))))
 val familyHBaseWriterOptions =
 new java.util.HashMap[Array[Byte], FamilyHFileWriteOptions]
 val f1Options = new FamilyHFileWriteOptions("GZ", "ROW", 128, "PREFIX")
 familyHBaseWriterOptions.put(Bytes.toBytes(columnFamily1), f1Options)
 rdd.hbaseBulkLoad(hbaseContext,
 TableName.valueOf(tableName),
 t => {
 val rowKey = t._1
 val family:Array[Byte] = t._2._1
 val qualifier = t._2._2
 val value = t._2._3
 val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
 Seq((keyFamilyQualifier, value)).iterator
 },
 stagingFolder,
 familyHBaseWriterOptions,
 compactionExclude = false,
 HConstants.DEFAULT_MAX_FILE_SIZE)
 val connection = HConnectionManager.createConnection(conf)
 val table = connection.getTable(TableName.valueOf(tableName))
 val load = new LoadIncrementalHFiles(conf)
 load.doBulkLoad(new Path(stagingFolder),
 connection.getAdmin, table,
 connection.getRegionLocator(TableName.valueOf(tableName)))
```

## Thin-Record Bulk Load Example

The following example shows how to call the thin-record bulk load implementation:

**Note:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{HBaseContext, _}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
val tableName = "table3"
 val stagingFolder = "/home/mapr"
 val columnFamily1 = "cf1"
 @transient val conf = HBaseConfiguration.create()
 val hbaseContext = new HBaseContext(sc, conf)
 conf.set(TableInputFormat.INPUT_TABLE, tableName)
 conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
 conf.setInt("hbase.zookeeper.property.clientPort", 5181)
 val rdd = sc.parallelize(Array(
 ("1", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("a")),
Bytes.toBytes("foo1")),
 ("3", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("b"),
Bytes.toBytes("foo2.b")))))
 rdd.hbaseBulkLoadThinRows(hbaseContext,
 TableName.valueOf(tableName),
 t => {
 val rowKey = t._1
 val familyQualifiersValues = new FamiliesQualifiersValues
 val q = t._2
 val family:Array[Byte] = q.head
 val qualifier = q(1)
 val value:Array[Byte] = q(2)
 println(s"family: $family")
 println(s"qualifier: $qualifier")
 println(s"value: $value")
 familyQualifiersValues +=(family, qualifier, value)
 (new ByteArrayWrapper(Bytes.toBytes(rowKey)),
familyQualifiersValues)}, stagingFolder, new java.util.HashMap[Array[Byte],
FamilyHFileWriteOptions], compactionExclude = false, 20)
 val connection = HConnectionManager.createConnection(conf)
 val table = connection.getTable(TableName.valueOf(tableName))
 val load = new LoadIncrementalHFiles(conf)
 load.doBulkLoad(
 new Path(stagingFolder),
 connection.getAdmin,
 table,
 connection.getRegionLocator(TableName.valueOf(tableName)))
```

The big difference in using bulk load for thin rows is that the function returns a tuple with the first value being the RowKey and the second value being an object of `FamiliesQualifiersValues`. `FamiliesQualifiersValues` contains all the values for this row for all column families.

### SparkSQL and DataFrames

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark leverages [DataSource API \(SPARK-3247\)](#) introduced in Spark-1.2.0. The connector bridges the gap between simple HBase KV store and complex relational SQL queries and enables users to perform complex data analytical work on

top of HPE Ezmeral Data Fabric Database binary tables using Spark. HBase DataFrame is a standard Spark DataFrame, and is able to interact with any other data sources, such as Hive, Orc, Parquet, JSON, and others. The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark applies critical techniques such as partition pruning, column pruning, predicate pushdown and data locality.

To use the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark, you need to define the Catalog for the schema mapping between HPE Ezmeral Data Fabric Database binary tables and Spark tables, prepare the data and populate the HPE Ezmeral Data Fabric Database binary table, then load the HBase DataFrame. After that, users can do integrated query and access records in a HPE Ezmeral Data Fabric Database binary table with SQL query. The following examples illustrate the basic procedure.

### Define Catalog Example

The `catalog` defines a mapping between HPE Ezmeral Data Fabric Database binary tables and Spark tables. There are two critical parts of this catalog. One is the rowkey definition. The other is the mapping between the table column in Spark and the column family and column qualifier in HPE Ezmeral Data Fabric Database binary table. The following example defines a schema for a HPE Ezmeral Data Fabric Database binary table with name as `my_table`, row key as `key` and a number of columns (`col1` - `col8`). Note that the rowkey also has to be defined in details as a column (`col10`), which has a specific `cf` (`rowkey`).

```
def catalog = s"""{
 | "table": {"namespace": "default", "name": "/path_to/my_table"},
 | "rowkey": "key",
 | "columns": {
 | | "col10": {"cf": "rowkey", "col": "key", "type": "string"},
 | | "col11": {"cf": "cf1", "col": "col11", "type": "boolean"},
 | | "col12": {"cf": "cf2", "col": "col12", "type": "double"},
 | | "col13": {"cf": "cf3", "col": "col13", "type": "float"},
 | | "col14": {"cf": "cf4", "col": "col14", "type": "int"},
 | | "col15": {"cf": "cf5", "col": "col15", "type": "bigint"},
 | | "col16": {"cf": "cf6", "col": "col16", "type": "smallint"},
 | | "col17": {"cf": "cf7", "col": "col17", "type": "string"},
 | | "col18": {"cf": "cf8", "col": "col18", "type": "tinyint"}
 | }
 |}
|}""".stripMargin
```

### Save the DataFrame Example

Data prepared by the user is a local Scala collection that has 256 HBaseRecord objects. The `sc.parallelize(data)` function distributes data to form an RDD. `toDF` returns a DataFrame. `writefunction` returns a DataFrameWriter used to write the DataFrame to external storage systems (e.g. HPE Ezmeral Data Fabric Database here). Given a DataFrame with a specified schema catalog, the `save` function creates a HPE Ezmeral Data Fabric Database binary table with five (5) regions and saves the DataFrame inside.

```
case class HBaseRecord(
 col0: String,
 col1: Boolean,
 col2: Double,
 col3: Float,
 col4: Int,
 col5: Long,
 col6: Short,
 col7: String,
 col8: Byte)

object HBaseRecord
{
 def apply(i: Int, t: String): HBaseRecord = {
```

```

 val s = s"" "row${"%03d".format(i)} ""
 HBaseRecord(s,
 i % 2 == 0,
 i.toDouble,
 i.toFloat,
 i,
 i.toLong,
 i.toShort,
 s"String$i: $t",
 i.toByte)
 }
}

val data = (0 to 255).map { i => HBaseRecord(i, "extra")}

sc.parallelize(data).toDF.write.options(Map(
 HBaseTableCatalog.tableCatalog -> catalog,
 HBaseTableCatalog.newTable -> "5")
).format("org.apache.hadoop.hbase.spark")
.save()

```

### Load the DataFrame Example

In the `withCatalog` function, `sqlContext` is a variable of `SQLContext`, which is the entry point for working with structured data (rows and columns) in Spark. `read` returns a `DataFrameReader` that can be used to read data in a `DataFrame`. The `option` function adds input options for the underlying data source to the `DataFrameReader`. The `format` function specifies the input data source format for the `DataFrameReader`. The `load()` function loads input as a `DataFrame`. The data frame `df` returned by the `withCatalog` function can be used to access the HPE Ezmeral Data Fabric Database binary table, as shown in the Language Integrated Query and SQL Query examples.

```

def withCatalog(cat: String): DataFrame = {
 sqlContext
 .read
 .options(Map(HBaseTableCatalog.tableCatalog->cat))
 .format("org.apache.hadoop.hbase.spark")
 .load()
}
val df = withCatalog(catalog)

```

### Language Integrated Query Example

`DataFrame` can do various operations, such as `join`, `sort`, `select`, `filter`, `orderBy`, and so on. In the following example, `df.filter` filters rows using the given SQL expression. `select` selects a set of columns: `col0`, `col1` and `col4`.

```

val s = df.filter(("col0" <= "row050" && "col0" > "row040") ||
 "col0" === "row005" ||
 "col0" <= "row005")
 .select("col0", "col1", "col4")
s.show

```

## SQL Query Example

`registerTempTable` registers `df` `DataFrame` as a temporary table using the table name `table1`. The lifetime of this temporary table is tied to the `SQLContext` that was used to create `df`. `sqlContext.sqlfunction` allows the user to execute SQL queries.

```
df.registerTempTable("table1")
sqlContext.sql("select count(col1) from table1").show
```

## Query with Different Timestamps

In `HBaseSparkConf`, you can set four parameters related to timestamp:

- `TIMESTAMP`
- `MIN_TIMESTAMP`
- `MAX_TIMESTAMP`
- `MAX_VERSIONS`

With `MIN_TIMESTAMP` and `MAX_TIMESTAMP`, you can query records with different timestamps or time ranges. In the meantime, use a concrete value instead of `tsSpecified` and `oldMs` in the following examples. The first example shows how to load `df` `DataFrame` with different timestamps. `tsSpecified` is specified by the user. `HBaseTableCatalog` defines the HBase and Relation relation schema. `writeCatalog` defines the catalog for the schema mapping.

```
val df = sqlContext.read
 .options(Map(
 HBaseTableCatalog.tableCatalog -> writeCatalog,
 HBaseSparkConf.TIMESTAMP -> tsSpecified.toString)
).format("org.apache.hadoop.hbase.spark")
 .load()
```

The following example shows how to load `df` `DataFrame` with different time ranges. `oldMs` is specified by the user.

```
val df = sqlContext.read
 .options(Map(
 HBaseTableCatalog.tableCatalog -> writeCatalog,
 HBaseSparkConf.MIN_TIMESTAMP -> "0",
 HBaseSparkConf.MAX_TIMESTAMP -> oldMs.toString)
).format("org.apache.hadoop.hbase.spark")
 .load()
```

After loading `df` `DataFrame`, users can query data.

```
df.registerTempTable("table")
sqlContext.sql("select count(col1) from table").show
```

## Native Avro Support

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark supports different data formats such as Avro, JSON, and others. The following use case shows how Spark supports Avro. You can persist the Avro record into HPE Ezmeral Data Fabric Database binary tables directly. Internally, the Avro schema is converted to a native Spark Catalyst data type automatically. Note that both key-value parts in a HPE Ezmeral Data Fabric Database binary table can be defined in Avro format.

1. Define the catalog for schema mapping. `catalog` is a schema for a HPE Ezmeral Data Fabric Database binary table named `Avrotable`, a row key as `key`, and one column `col1`. The rowkey also has to be defined in details as a column (`col0`), which has a specific `cf` (`rowkey`).

```
def catalog = s"""{
 "table": {"namespace": "default", "name": "/path_to/
 avro_table"},
 "rowkey": "key",
 "columns": {
 "col0": {"cf": "rowkey", "col": "key",
 "type": "string"},
 "col1": {"cf": "cf1", "col": "col1", "type": "binary"}
 }
}""".stripMargin
```

2. Prepare the data. `schemaString` is defined first. Then it is parsed to get `avroSchema`. `avroSchema` is used to generate `AvroHBaseRecord`. data prepared by users is a local Scala collection that has 256 `AvroHBaseRecord` objects.

```
object AvroHBaseRecord {
 val schemaString =
 s"""{"namespace": "example.avro",
 "type": "record", "name": "User",
 "fields": [
 {"name": "name", "type": "string"},
 {"name": "favorite_number", "type": ["int", "null"]},
 {"name": "favorite_color", "type": ["string", "null"]},
 {"name": "favorite_array", "type": {"type": "array",
"items": "string"}},
 {"name": "favorite_map", "type": {"type": "map",
"values": "int"}}
] }""".stripMargin

 val avroSchema: Schema = {
 val p = new Schema.Parser
 p.parse(schemaString)
 }

 def apply(i: Int): AvroHBaseRecord = {
 val user = new GenericData.Record(avroSchema);
 user.put("name", s"name${"%03d".format(i)}")
 user.put("favorite_number", i)
 user.put("favorite_color", s"color${"%03d".format(i)}")
 val favoriteArray = new GenericData.Array[String](
 2,
 avroSchema.getField("favorite_array").schema()
)
 favoriteArray.add(s"number${i}")
 favoriteArray.add(s"number${i+1}")
 user.put("favorite_array", favoriteArray)
 import collection.JavaConverters._
 val favoriteMap = Map[String, Int](("key1" -> i), ("key2" ->
(i+1))).asJava
 user.put("favorite_map", favoriteMap)
 val avroByte = AvroSedes.serialize(user, avroSchema)
 AvroHBaseRecord(s"name${"%03d".format(i)}", avroByte)
 }
}

val data = (0 to 255).map { i =>
 AvroHBaseRecord(i)
}
```

3. Save the DataFrame. Given a data frame with the specified schema catalog, the following example creates a HPE Ezmeral Data Fabric Database binary table with five (5) regions and saves the data frame inside.

```
sc.parallelize(data).toDF.write.options(
 Map(
 HBaseTableCatalog.tableCatalog -> catalog,
 HBaseTableCatalog.newTable -> "5")
).format("org.apache.spark.sql.execution.datasources.hbase")
.save()
```

4. Load the DataFrame. In the `withCatalog` function, `read` returns a `DataFrameReader` that can be used to read data in as a `DataFrame`. The `option` function adds input options for the underlying data source to the `DataFrameReader`. There are two options: one is to set `avroSchema` as `AvroHBaseRecord.schemaString`. The other option is to set `HBaseTableCatalog.tableCatalog` as `avroCatalog`. The `load()` function loads input in as a `DataFrame`. The data frame `df` returned by the `withCatalog` function can be used to access the HPE Ezmeral Data Fabric Database binary table.

```
def avroCatalog = s"""{
 | "table": {"namespace": "default", "name": "avrotable"},
 | "rowkey": "key",
 | "columns": {
 | | "col0": {"cf": "rowkey", "col": "key", "type": "string"},
 | | "col1": {"cf": "cf1", "col": "col1", "avro": "avroSchema"}
 | }
 |}""" .stripMargin

def withCatalog(cat: String): DataFrame = {
 sqlContext
 .read
 .options(Map(
 "avroSchema" -> AvroHBaseRecord.schemaString,
 HBaseTableCatalog.tableCatalog -> avroCatalog)
).format("org.apache.spark.sql.execution.datasources.hbase")
 .load()
}
val df = withCatalog(catalog)
```

5. Query data using SQL. After loading `df` `DataFrame`, you can query data. `registerTempTable` registers `df` `DataFrame` as a temporary table using the table name `avrotable`. The `sqlContext.sql` function allows you to execute SQL queries.

```
df.registerTempTable("avrotable")
val c = sqlContext.sql("select count(1) from avrotable")
```

### Integrating Spark

This section includes the following topics about configuring Spark to work with other ecosystem components.

#### Integrate Spark-SQL (Spark 2.3.1 and later) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 2.3.0 or later users.

**Note:** For Spark 2.2.1 and 2.3.1 versions, use the 4.0.0 avro version of `com.databricks:spark-avro_2.11`.

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

1. Download the Avro 1.7.7 JAR file to the Spark `jars` (`opt/mapr/spark/spark-<version>/jars`) directory.

You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>

2. Add the following properties in `spark-defaults.conf`:

```
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
spark.executor.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
```

### Integrate Spark-SQL (Spark 1.6.1) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 1.6.1 or earlier users.

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

1. Download the Avro 1.7.7 JAR file to the Spark lib (`opt/mapr/spark/spark-<version>/lib`) directory.

You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>

2. Use one of the following methods to add the Avro 1.7.7 JAR to the classpath:

- Prepend the Avro 1.7.7 JAR file to the `spark.executor.extraClassPath` and `spark.driver.extraClassPath` in the `spark-defaults.conf` (`/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf`) file:

```
spark.executor.extraClassPath /opt/mapr/spark/
spark-<spark_version>/lib/avro-1.7.7.jar:<rest_of_path>
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/lib/
avro-1.7.7.jar:<rest_of_path>
```

- Specify the Avro 1.7.7 JAR files with command line arguments on the spark shell:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell \
--packages com.databricks:spark-avro_2.10:2.0.1 \
--driver-class-path /opt/mapr/spark/spark-<version>/lib/avro-1.7.7.jar \
--conf spark.executor.extraClassPath=/opt/mapr/spark/
spark-<version>/lib/avro-1.7.7.jar --master <master-url>
```

### Integrate Spark with HBase

Integrate Spark with HBase or HPE Ezmeral Data Fabric Database when you want to run Spark jobs on HBase or HPE Ezmeral Data Fabric Database tables.

If you installed Spark with the MapR Installer, these steps are not required.

1. Configure the HBase version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hbase_versions=<version>
```

The HBase version depends on the current EEP and MapR version that you are running.

2. If you want to create HBase tables with Spark, add the following property to `hbase-site.xml`:

```
<property>
hbase.table.sanity.checks</name>
<value>>false</value>
</property>
```

- On each Spark node, copy the `hbase-site.xml` to the `{SPARK_HOME}/conf/` directory.

**Tip:** Starting in the EEP 7.0.0 release, you do not have to complete step 3. Running `configure.sh` copies the `hbase-site.xml` file to the Spark directory automatically.

- Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
spark.yarn.dist.files SPARK_HOME/conf/hbase-site.xml
```

- To verify the integration, complete the following steps:

- Create an HBase or HPE Ezmeral Data Fabric Database table:

```
create '<table_name>' , '<column_family>'
```

- Run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
/opt/mapr/spark/spark-<spark_version>/bin/spark-submit --master
<master> [--deploy-mode <deploy-mode>] --class
org.apache.hadoop.hbase.spark.example.rdd.HBaseBulkPutExample /opt/
mapr/hbase/hbase-<hbase_version>/lib/
hbase-spark-<hbase_version>-mapr.jar <table_name> <column_family>
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn`, or `local` (without `deploy-mode`). The `deploy-mode` is either `client` or `cluster`.

- Check the data in the HBase or MapR-DB table:

```
hbase(main):001:0> scan '<table_name>'
```

### Integrate Spark-SQL (Spark 2.0.1 and later) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 2.0.1 or later users.

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

**Note:** If you installed Spark with the MapR Installer, the following steps are not required.

- Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration. Do not create a symbolic link instead of copying the file. You may need to edit the file with settings that are specific to the Spark Thrift server.
- Add 644 permission to the `hive-site.xml` using the following command:

```
sudo chmod 644 /opt/mapr/spark/spark-<sparkVersion>/conf/hive-site.xml
```

- If Hive is configured on Tez (not on MR), you must remove the Tez property from the Spark conf directory `hive-site.xml`. Delete this entry:

```
<property>
 <name>hive.execution.engine</name>
 <value>tez</value>
</property>
```

- If Hive is configured on PAM, set "hive.metastore.sasl.enabled = true" in the `hive-site.xml` located in the Spark conf directory.
- Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

| Property                                      | Configuration Requirements                                                                                                                                                                                        |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>spark.yarn.dist.files</code>            | For Spark on YARN, specify the location of the <code>hive-site.xml</code> file:<br><br><pre>/opt/mapr/spark/spark-&lt;spark-version&gt;/conf/hive-site.xml</pre>                                                  |
| <code>spark.sql.hive.metastore.version</code> | Specify the Hive version that you are using.<br><br> <b>Note:</b> If you are using Hive Metastore 2.1, set the version to 1.2.1. |

- Depending on whether you plan to run with impersonation, perform one of the following:
  - Configure user impersonation. See [Hive User Impersonation](#) for the steps to configure impersonation in the Spark Thrift server.
  - Set `hive.server2.enable.doAs` to `false` in the `hive-site.xml` file.
- To verify the integration, run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
<spark-home>/bin/run-example --master <master> [--deploy-mode <deploy-mode>] sql.hive.SparkHiveExample
```

The master URL for the cluster is either `spark://<host>:7077` or `yarn`. The `deploy-mode` is either `client` or `cluster`.

**Note:** The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

**Note:** If you plan to access Hive tables that store data in HPE Ezmeral Data Fabric Database, you need to copy the Hive HBase handler jar into the Spark jars directory. For example:

```
cp /opt/mapr/hive/hive-2.1/lib/hive-hbase-handler-2.1.1-mapr-1707.jar /opt/mapr/spark/spark-2.1.0/jars/
```

### Integrate Spark-SQL (Spark 1.6.1) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 1.6.1 or earlier users.

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

**Note:** If you installed Spark with the MapR Installer, the following steps are not required.

- Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration.

- Configure the Hive version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hive_versions=<version>
```

- Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

| Property                         | Configuration Requirements                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| spark.yarn.dist.files            | <p>Option 1: For Spark on YARN, specify the location of the <code>hive-site.xml</code> and the datanucleus JARs:</p> <pre>/opt/mapr/hive/hive-&lt;hive-version&gt;/conf/hive-site.xml,/opt/mapr/hive/&lt;version&gt;/lib/datanucleus-api-jdo-&lt;version&gt;.jar,/opt/mapr/hive/&lt;version&gt;/lib/datanucleus-core-&lt;version&gt;.jar,/opt/mapr/hive/hive-1.2/lib/datanucleus-rdbms-&lt;version&gt;.jar</pre> <p>Option 2: For Spark on YARN, store <code>hive-site.xml</code> and datanucleus JARs on filesystem, and use the following syntax:</p> <pre>maprfs:///&lt;path to hive-site.xml&gt;,maprfs:///&lt;path to datanucleus jar files&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| spark.sql.hive.metastore.version | Specify the Hive version that you are using. For example, for Hive 1.2.x, set the value to 1.2.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| spark.sql.hive.metastore.jars    | <p>Specify the classpath to JARs for Hive, Hive dependencies, and Hadoop. These files must be available on the node from which you submit Spark jobs:</p> <pre>/opt/mapr/hadoop/hadoop-&lt;hadoop-version&gt;/etc/hadoop:/opt/mapr/hadoop/hadoop-&lt;hadoop-version&gt;/share/hadoop/common/lib/*:&lt;rest of hadoop classpath&gt;:/opt/mapr/hive/hive-&lt;version&gt;/lib/accumulo-core-&lt;version&gt;.jar:/opt/mapr/hive/hive-&lt;version&gt;/lib/hive-contrib-&lt;version&gt;.jar:&lt;rest of hive classpath&gt;</pre> <p>For example, when you run with Hive 1.2, you can set the following classpath:</p> <pre>/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/*:/opt/mapr/hadoop/.hadoop-2.7.0/share/hadoop/mapreduce/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/yarn/*:/opt/mapr/hive/hive-1.2/lib/accumulo-core-1.6.0.jar:/opt/mapr/hive/hive-1.2/lib/hive-contrib-1.2.0-mapr-1607.jar:/opt/mapr/hive/hive-1.2/lib/*</pre> <p>For more information, see the <a href="#">Apache Spark documentation</a>.</p> |

- To verify the integration, run the following command as the mapr user or as a user that mapr impersonates:

```
MASTER=<master-url> <spark-home>/bin/run-example sql.hive.HiveFromSpark
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn-client`, or `yarn-cluster`.

**Note:** The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

### Integrate Spark with HPE Ezmeral Data Fabric Event Streams

Integrate Spark with MapR Streams to enable Spark to query HPE Ezmeral Data Fabric Event Streams for new messages at a given interval, process any new messages that are available, and also publish messages into HPE Ezmeral Data Fabric Event Streams.

You can use Spark to access HPE Ezmeral Data Fabric Event Streams through Spark's receiver-less, direct approach.

For more information, see the [Apache Spark documentation](#).

**Note:** Before you integrate Spark with HPE Ezmeral Data Fabric Event Streams, verify that the Streams Client is installed on all Spark nodes. For more information, see the [Installing Core and Ecosystem Components](#) on page 87.

#### *Configure Spark 2.2.1 and later to Consume HPE Ezmeral Data Fabric Event Streams Messages*

Using the Kafka 0.9 API, you can configure a Spark application to query HPE Ezmeral Data Fabric Event Streams for new messages at a given interval. This information is for Spark 2.2.1 and later users.

- Install the [MapR core Kafka package](#), if you have not already done so.
- Copy the Kafka client jar into the Spark jars directory as shown below:

```
cp /opt/mapr/lib/kafka-clients-<version>.jar SPARK_HOME/jars
```

- Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-0-9_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

**Note:** If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`).

- Consider the following when you write the Spark application:
  - Verify that it meets the following requirements:
    - Imports and use classes from `org.apache.spark.streaming.kafka09`. The following code snippet imports three classes.

```
import org.apache.spark.streaming.kafka09.{ConsumerStrategies,
KafkaUtils, LocationStrategies}
```

- Defines key and value deserializers in the kafkaParams map.

```
val kafkaParams = Map[String, String](
 ConsumerConfig.GROUP_ID_CONFIG -> groupId,
 ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG ->
 "org.apache.kafka.common.serialization.StringDeserializer",
 ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG ->
 "org.apache.kafka.common.serialization.StringDeserializer",
 ConsumerConfig.AUTO_OFFSET_RESET_CONFIG -> offsetReset)
```

- Does not configure a broker address or Zookeeper as these are not required for HPE Ezmeral Data Fabric Event Streams.
- b) Optionally, define a value for `spark.streaming.kafka.consumer.poll.ms` in the Spark configuration.

**Note:** You can configure the poll timeout using Spark option `spark.streaming.kafka.consumer.poll.ms`. If you do not configure `spark.streaming.kafka.consumer.poll.ms`, the `spark.network.timeout` property is used. If `spark.network.timeout` is empty, the default is 120 seconds.

```
val sparkConf = new SparkConf()
 .setAppName("v09DirectKafkaWordCount")
 .set("spark.streaming.kafka.consumer.poll.ms", pollTimeout)
```

Example:

<https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/V09DirectKafkaWordCount.scala> is a sample consumer program.

The `KafkaUtils.createDirectStream` method creates an input stream to read HPE Ezmeral Data Fabric Event Streams messages. The `ConsumerStrategies.Subscribe` method creates the consumer strategy that will limit the set of topics the stream subscribes to. This is derived from the `topics` parameter passed into the program. Using `LocationStrategies.PreferConsistent` will distribute partitions evenly across available executors.

```
val consumerStrategy = ConsumerStrategies.Subscribe[String, String](
 topicsSet, kafkaParams)
val messages = KafkaUtils.createDirectStream[String, String](
 ssc, LocationStrategies.PreferConsistent, consumerStrategy)
```

### Configure Spark to Produce HPE Ezmeral Data Fabric Event Streams Messages

Using the Kafka 0.9 API, you can configure a Spark application to produce MapR Streams messages.

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

**Note:** If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`).

- When you write the Spark program, import and use classes from `org.apache.spark.streaming.kafka.producer._` and `org.apache.spark.streaming.dstream`.

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter.

```
val producerConf = new ProducerConf(bootstrapServers =
 kafkaBrokers.split(",").toList)
 .withKeySerializer("org.apache.kafka.common.serialization.ByteArraySerializer")
 .withValueSerializer("org.apache.kafka.common.serialization.StringSerializer")

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
 defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

The `org.apache.kafka.common.serialization.ByteArraySerializer` and `org.apache.kafka.common.serialization.StringSerializer` properties are used by default, and in case you do not want to use another serializer, `withKeySerializer` and `withValueSerializer` methods are not necessary.

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

### Integrate Spark with R

You integrate Spark with R when you want to run R programs as Spark jobs.

- On each node that will submit Spark jobs, install R 3.2.2 or greater:

- On Ubuntu:

```
apt-get install r-base-dev
```

- On CentOS/RedHat:

```
yum install R
```

For more information about installing R, see the [R documentation](#).

- To verify the integration, run the following commands as the `mapr` user or as a user that `mapr` impersonates:
  - Start Spark R:

- On Spark 2.0.1, 2.1.0, and later:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master>
[--deploy-mode <deploy-mode>]
```

- On Spark 1.6.1:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master-url>
```

- b) Run the following command to create a DataFrame using sample data:

On Spark 1.6.1:

```
people <- read.df(sqlContext, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

On Spark 2.0.1, 2.1.0, and later:

```
people <- read.df(spark, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

- c) Run the following command to display the data from the DataFrame that you just created:

```
head(people)
```

### Integrate Spark with Kafka

From EEP-5.0.0, Spark can be integrated with Kafka-1.0. You can configure a Spark application to produce Kafka messages.

**Note:** Starting from EEP-8.0.0, HPE Ezmeral Data Fabric does not support `spark-streaming-kafka-producer`. To learn about Kafka integration on Apache Spark 3.1.2 and later in HPE Ezmeral Data Fabric, see [Structured Streaming + Kafka Integration Guide \(Kafka broker version 0.10.0 or higher\)](#).

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

2. When you write the Spark program, import and use classes from:

```
org.apache.spark.streaming.kafka.producer._
org.apache.spark.streaming.dstream.
```

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

3. In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter:

```
val producerConf = new ProducerConf(
 bootstrapServers = kafkaBrokers.split(",").toList)

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
 defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

### Spark JDBC and ODBC Drivers

MapR provides JDBC and ODBC drivers so you can write SQL queries that access the Apache Spark data-processing engine. This section describes how to download the drivers, and install and configure them.

You can download the Spark JDBC driver from [https://package.mapr.hpe.com/tools/MapR-JDBC/MapR\\_Spark/](https://package.mapr.hpe.com/tools/MapR-JDBC/MapR_Spark/) and the Spark ODBC driver from [https://package.mapr.hpe.com/tools/MapR-ODBC/MapR\\_Spark/](https://package.mapr.hpe.com/tools/MapR-ODBC/MapR_Spark/).

After downloading the driver, refer to the documentation at [Spark JDBC Driver](#) to install and configure the JDBC driver and [Spark ODBC Driver](#) for the ODBC driver. A copy of the documentation also is available in each download package. The following table describes the driver versions available for various EEP releases:

|              | EEP version | Driver version | Driver link                                         | Documentation link                                         |
|--------------|-------------|----------------|-----------------------------------------------------|------------------------------------------------------------|
| JDBC version | EEP 6.0.0+  | 2.6.3          | <a href="#">Spark JDBC Driver for version 2.6.3</a> | <a href="#">Spark JDBC Documentation for version 2.6.3</a> |
|              | EEP 3.0.1+  | 1.1.8          | <a href="#">Spark JDBC Driver for version 1.1.8</a> | <a href="#">Spark JDBC Documentation for version 1.1.8</a> |
| ODBC version | EEP 6.0.0+  | 2.6.1          | <a href="#">Spark ODBC Driver for version 2.6.1</a> | <a href="#">Spark ODBC Documentation for version 2.6.1</a> |
|              | EEP 2.0.2+  | 1.2.5          | <a href="#">Spark ODBC Driver for version 1.2.5</a> | <a href="#">Spark ODBC Documentation for version 1.2.5</a> |

**Note:** When connecting to the Spark Thrift Server using `beeline` and the JDBC driver, you might encounter the following error:

```
"Unsupported transaction isolation level: 4"
```

To avoid this error, pass the `isolation` parameter to `beeline` as follows:

```
bin/beeline --isolation=default
```

## Spark API Changes

This topic describes the public API changes that occurred for specific Spark versions.

### Spark 2.3.1 API Changes

EEP 6.0.0 supports Spark version 2.3.1.

For more information about Spark 2.3.1, see the [Spark 2.3.1-1808 \(EEP 6.0.0\) Release Notes](#) on page 6582 and the [Spark 2.3.1 API Documentation](#).

For a complete list of all new and changed APIs, refer to the [open source documentation](#).

### Spark 2.1.0 API Changes

This topic describes the public API changes that occurred between Apache Spark 2.0.1 and Spark 2.1.0.

For more information about Spark 2.1.0, see the [Spark Release Notes](#) and the [Spark 2.1.0 API Documentation](#).

## New API

- The `DataTypes` API is now mostly stable. Please see `InterfaceStability` annotations for the classes you need.
- Add the `from_json` and `to_json` functions to SQL.
- `StructType` now accepts Python Dictionaries.
- New ML algorithms have been added for Spark R.
- `SparkContext.addFile` is now supported for SparkR.
- SparkR now supports multinomial logistics regression.
- MLlib supports MLR in DataFrames, LSH.
- MLlib model loading is now backward-compatible with Spark 1.6.

## Changed API

- Parquet-MR is bumped to 1.8.1.
- `spark.sql.warehouse.dir` now needs to be set before `SparkSession` creation and is shared between multiple `SparkSessions`.
- Values generated by non-deterministic functions will not change after coalesce or union.
- The default `Locale` for `DateFormat/NumberFormat` is now `Locale.US`.
- Function `SIZE` returns -1 when its input parameter is null.

### Spark 2.0.1-1703 API Changes

This release does not introduce any changes to public Spark API apart from Structured Streaming, which is not supported by the MapR platform.

### Spark 2.0.1-1611 API Changes

This topic describes the public API changes that occurred between Apache Spark 1.6.1 and Spark 2.0.1.

## Removed Methods

The following items have been removed from [Apache Spark 2.0.1](#):

- Bagel (the Spark implementation of Google Pregel)

- Most of the deprecated methods from Spark 1.x, including:

| Category         | Subcategory                                          | Instead of this removed API..                                  | Use...                                                |                             |
|------------------|------------------------------------------------------|----------------------------------------------------------------|-------------------------------------------------------|-----------------------------|
| GraphX           |                                                      | mapReduceTriplets                                              | aggregateMessages                                     |                             |
|                  |                                                      | runSVDPlusPlus                                                 | run                                                   |                             |
|                  |                                                      | GraphKryoRegistrar                                             |                                                       |                             |
| SQL              | DataType                                             | DataType.fromCaseClassString                                   | DataType.fromJson                                     |                             |
|                  | DecimalType                                          | DecimalType()                                                  | DecimalType(precision, scale)<br>precision explicitly |                             |
|                  |                                                      | DecimalType(Option[PrecisionInfo])                             | DecimalType(precision scale)                          |                             |
|                  |                                                      | PrecisionInfo                                                  | DecimalType(precision, scale)                         |                             |
|                  |                                                      | precisionInfo                                                  | precision and scale                                   |                             |
|                  |                                                      | Unlimited                                                      | (No longer supported)                                 |                             |

|                                  |                  | filterWith                                                                                                                                 | mapPartitionsWithIndex and filt       |
|                                  |                  | toArray                                                                                                                                    | collect                               |
|                                  | TaskInfo         | TaskInfo.attempt                                                                                                                           | TaskInfo.attemptNumber                |
|                                  | Guava Optional   | Guava Optional                                                                                                                             | org.apache.spark.api.java.Opt         |
|                                  | Vector           | Vector, VectorSuite                                                                                                                        |                                       |
| Configuration options and params |                  | --name                                                                                                                                     |                                       |
|                                  |                  | --driver-memory                                                                                                                            | spark.driver.memory                   |
|                                  |                  | --driver-cores                                                                                                                             | spark.driver.cores                    |
|                                  |                  | --executor-memory                                                                                                                          | spark.executor.memory                 |
|                                  |                  | --executor-cores                                                                                                                           | spark.executor.cores                  |
|                                  |                  | --queue                                                                                                                                    | spark.yarn.queue                      |
|                                  |                  | --files                                                                                                                                    | spark.yarn.dist.files                 |
|                                  |                  | --archives                                                                                                                                 | spark.yarn.dist.archives              |
|                                  |                  | --addJars                                                                                                                                  | spark.yarn.dist.jars                  |
|                                  |                  | --py-files                                                                                                                                 | spark.submit.pyFiles                  |

Note also the following deprecated configuration options and parameters:

- Methods from Python `DataFrame` that returned RDD have been moved to `dataframe.rdd`. For example, `df.map` is now `df.rdd.map`.
- Some streaming connectors (Twitter, Akka, MQTT, and ZeroMQ) have been removed.
- `org.apache.spark.shuffle.hash.HashShuffleManager` no longer exists. `SortShuffleManager` is the default since Spark 1.2.
- `DataFrame` is no longer a class. It is a subtype of `DataSet`.

## Behavior Changes

Spark 2.0.1 implements the following behavior changes:

- Spark 2.0.1 uses Scala 2.11 instead of 2.10.
- Floating literals in SQL are now parsed as decimal type instead of double type.
- The Kryo version is now 3.0.
- Jersey version is now 2.
- Java RDD `flatMap` and `mapPartitions` functions now require functions that return Java iterator instead of `Iterable`.
- Java RDD `countByKey` and `countApproxDistinctByKey` now return `Map[K => Long]` instead of `Map[K => Object]`.
- When writing Parquet files, the summary files are no longer written (set `parquet.enable.summary-metadata` to `true` to re-enable).
- Lots were changed in MLLib. Follow the [Apache Spark Migration Guide](#).
- `SparkContext.emptyRDD` now returns RDD instead of `EmptyRDD`.
- Spark Standalone Master no longer serves the jobs history.
- [org.apache.spark.api.java.JavaPairRDD](#) methods were changed:
  - `countByKey` and `countApproxDistinctByKey` now return `java.lang.Long` instead of `scala.Long`.
  - `sampleByKey` and `sampleByKeyExact` now return `java.lang.Double` instead of `scala.Double`.
- The Old Application History format that created folders for each application has been removed.
- `org.apache.spark.Logging` is now private. You can use `slf4j` directly instead.

## Other Deprecated Items

- Java 7 is now deprecated.
- Python 2.6 is now deprecated.
- [TaskContext.isRunningLocally](#) now is always false, as there is no more local execution of `yarn-client` and `yarn-cluster` as masters. Use `--master yarn` and `--deploy-mode client/cluster`.

- Instead of `HiveContext`, use `SparkSession.builder.enableHiveSupport`.
- Instead of `SQLContext`, use `SparkSession.builder`.
- Some methods related to `Accumulators`, `ShuffleWriteMetrics`, `SparkLoop`, `DataSet`, and `SQLContext` are now deprecated. You will see warnings in your application logs if you use them.

### Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

#### Related Links

Spark streaming is integrated with HPE Ezmeral Data Fabric Event Streams for Apache Kafka.

- [MapR Event Store For Apache Kafka Clients and Tools](#)

### Prerequisites for Using Structured Streaming in Spark

To deploy a structured streaming application in Spark, you must create a MapR Streams topic and install a Kafka client on all nodes in your cluster.

#### *Creating a MapR Streams Topic*

- Create a MapR Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

#### *Installing a Kafka Client*

- Install a `kafka-client` on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

### Using Structured Streaming to Create a Word Count Application

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

#### *Using Apache Kafka*

##### Scala

```
val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCo
unt")
 .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.server
s", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS
STRING)")
 .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()
//Run the query that prints the
running counts to the console
```

**Java**

```

val query = wordCounts.writeStream
 .outputMode("complete")
 .format("console")
 .option("checkpointLocation",
checkpointLocation)
 .start()

query.awaitTermination()

```

```

SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructured
KafkaWordCount")
 .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap
.servers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value
AS STRING)")
 .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
 .outputMode("complete")
 .format("console")
 .start();

query.awaitTermination();

```

**Python**

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWor
dCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.ser
vers", bootstrapServers)\
 .option(subscribeType,

```

```

topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
 .writeStream\
 .outputMode('complete')\
 .format('console')\
 .start()

query.awaitTermination()

```

### Using MapR Event Store for Apache Kafka

For MapR Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```

var topic: String = "/user/mapr/stream:reviews"
val dfl = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
"maprdemo:9092").option("subscribe", topic).option("group.id",
"testgroup").option("startingOffsets",
"earliest").option("failOnDataLoss",
false).option("maxOffsetsPerTrigger", 1000).load()

```

### Writing a Structured Spark Stream to HPE Ezmeral Data Fabric Database JSON Table

The example in this section writes a structured stream in Spark to HPE Ezmeral Data Fabric Database JSON table.

To write a structured Spark stream to HPE Ezmeral Data Fabric Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

#### Scala

```

import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

```

**Java**

```
df.select($"value" as "_id")
 .writeStream
 .format(MapRDBSourceConfig.Format)
 .option(MapRDBSourceConfig.TablePath
Option, "/table/path")
 .option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
 .option(MapRDBSourceConfig.CreateTab
leOption, true)
 .option(MapRDBSourceConfig.BulkModeO
ption, true)
 .option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
 .outputMode("append")
 }
```

```
import
com.mapr.db.spark.streaming.MapRDBSour
ceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
org.apache.spark.sql.streaming.DataStr
eamReader;
import
org.apache.spark.sql.streaming.DataStr
eamWriter;
import
org.apache.spark.sql.streaming.Streami
ngQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
 return df.selectExpr("CAST(value
AS STRING) as _id")
 .writeStream()
 .format(MapRDBSourceConfig
.Format())
 .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
 .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
 .option(MapRDBSourceConfig
.CreateTableOption(), true)
 .option(MapRDBSourceConfig
.BulkModeOption(), true)
 .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
 .outputMode("append");
}
```

**Python**

```
from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
 return df.selectExpr("CAST(value AS
STRING) as _id") \
```

```

 .writeStream \
 .format("com.mapr.db.spark.
streaming") \
 .option("checkpointLocation
", checkpoint_dir) \
 .option("tablePath",
table_path) \
 .option("idFieldPath",
"value") \
 .option("createTable",
True) \
 .option("bulkMode", True) \
 .option("sampleSize", 1000)

```

### Writing a Spark Stream Word Count Application to HPE Ezmeral Data Fabric Database

The example in this section writes a Spark stream word count application to HPE Ezmeral Data Fabric Database.

#### Scala

```

val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCou
nt")
 .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.servers
", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS
STRING)")
 .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
 .format(MapRDBSourceConfig.Forma
t)
 .option(MapRDBSourceConfig.Table
PathOption, resultTable)
 .option(MapRDBSourceConfig.Creat
eTableOption, true)
 .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
 .outputMode("complete")
 .start()

query.awaitTermination()

```

**Java**

```

SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructuredKaf
kaWordCount")
 .getOrCreate();

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap.s
ervers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value
AS STRING)")
 .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
 .format(MapRDBSourceConfig
.Format())
 .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
 .option(MapRDBSourceConfig
.CreateTableOption(), true)
 .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
 .outputMode("complete");
 .start();

query.awaitTermination();

```

**Python**

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWo
rdCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.ser
vers", bootstrapServers)\
 .option(subscribeType,

```

```

topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
 .writeStream\
 .format("com.mapr.db.spa
rk.streaming") \
 .option("tablePath",
table_path) \
 .option("createTable",
True) \
 .option("idFieldPath",
"value") \
 .outputMode('complete')\
 .start()

query.awaitTermination()

```

### PAM Authentication for Spark

Spark supports PAM authentication on secure MapR clusters.

In EEP-5.0.0, PAM authentication and encryption is enabled by default for all Spark Web UIs. After running `configure.sh`, if the cluster is secure and Spark is installed, Spark will be configured using PAM.

**Note:** Spark PAM is available in Spark-2.2.1 from EEP-5.0 and in Spark-2.1.0 from EEP-4.1.1.

See [Configuring PAM](#) on page 1559 for information on how PAM works with MapR.

### Read or Write LZO Compressed Data for Spark

This topic provides details for reading or writing LZO compressed data for Spark.

1. Install the LZO library:

```
sudo yum install lzo-devel lzo
```

2. Clone `hadoop-lzo` and build it:

```
[mapr@node1 ~]$ git clone https://github.com/twitter/hadoop-lzo
[mapr@node1 ~]$ cd hadoop-lzo
[mapr@node1 hadoop-lzo]$ mvn package
```

**3. Copy the jar file to hadoop classpath:**

```
[mapr@node1 hadoop-lzo]$ sudo
cp target/hadoop-lzo-0.4.21-SNAPSHOT.jar /opt/mapr/hadoop/hadoop-2.7.0/
share/hadoop/yarn/lib/
```

**4. Add two LZO compression codes to core-site.xml:**

```
property: io.compression.codecs
codecs:
com.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec/
```

It will look like this:

```
<property>
 <name>io.compression.codecs</name>

 <value>org.apache.hadoop.io.compress.DefaultCodec,org.apache.hadoop.io.co
mpress.GzipCodec,org.apache.hadoop.io.compress.BZip2Codec,org.apache.hado
op.io.compress.DeflateCodec,org.apache.hadoop.io.compress.SnappyCodec,com
.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec</
value>
</property>

<property>
 <name>io.compression.codec.lzo.class</name>
 <value>com.hadoop.compression.lzo.LzoCodec</value>
</property>
```

**5. Run Spark and read LZO compressed data:**

```
[mapr@node1 spark]$./bin/spark-shell --master yarn
spark.read.csv("/user/mapr/LzoCompressedCsv").show
```

**6. Write LZO compressed data with Spark:**

```
scala>
df.write.option("codec","com.hadoop.compression.lzo.LzopCodec").csv("csv1
")

[mapr@node1 spark]$ hadoop fs -ls /user/mapr/csv1
Found 2 items
-rwxr-xr-x 3 mapr mapr 0 2017-12-15 12:42 /user/mapr/csv1/
_SUCCESS
-rwxr-xr-x 3 mapr mapr 493366 2017-12-15 12:42 /user/mapr/csv1/
part-00000-256a95a9-eb9c-4048-b7ce-c95dfbef54d7.csv.lzo
```

**Ports Used by Spark**

To run a Spark job from a client node, ephemeral ports should be opened in the cluster for the client from which you are running the Spark job.

If you do not want to open all the ephemeral ports, you can use the configuration parameter to specify the range of ports.

To set ports to special values, use the `spark.driver.port`, `spark.blockManager.port`, and `spark.port.maxRetries` properties. The `spark.port.maxRetries` property is 16 by default.

For example, if you need to open port 200 for `spark.blockManager.port` from 40000, set `spark.blockManager.port = 40000` and `spark.port.maxRetries = 200`.

For a list of Web UIs ports dynamically used when starting spark contexts, see the [open source documentation](#).

The default port numbers that need to be opened on the firewall behind the client and MapR cluster nodes for Spark jobs to operate in YARN client, YARN cluster, and standalone modes are as follows:

| Service                                                             | Port Number  |
|---------------------------------------------------------------------|--------------|
| Spark Standalone Master (RPC)                                       | 7077         |
| Spark Standalone Master (Web UI)                                    | 8580, 8980*  |
| Spark Standalone Worker                                             | 8581, 8981*  |
| Spark Thrift Server                                                 | 2304         |
| Spark History Server                                                | 18080,18480* |
| Spark External Shuffle Service (if yarn shuffle service is enabled) | 7337         |
| CLDB                                                                | 7222         |
| ZooKeeper                                                           | 5181         |
| Nodes running ResourceManager                                       | 8032         |
| MapR Filesystem Server                                              | 5660, 5692   |

\* refers to ports for secure clusters

### ACL Configuration for Spark

Starting in the EEP 6.0 release, the ACL configuration for Spark is disabled by default.

If you are authorized by PAM, you will have access to all Spark UIs. For the Spark History Server, you can only see the logs of your own Spark jobs if PAM is enabled (regardless of ACL being enabled).

Starting in Spark-2.4.4.0, MapR Spark ACLs behave like Apache Spark ACLs. With this change, all users can log in to the Spark History Server UI and see the full list of applications. Only an application owner or the users specified in `spark.ui.view.acls` or `history.ui.admin.acls` can see application details. Users specified in `history.ui.admin.acls` can see the details for all applications.

By default on a secure cluster:

```
spark.acls.enable false
spark.admin.acls mapr
spark.admin.acls.groups mapr
spark.ui.view.acls mapruser1
```

Other Example:

```
spark.acls.enable true - ACL is enabled and restricted access to Spark
master and thriftserver UIs for other users.
spark.admin.acls mapr - Administrator or "sudoer" of ACL access.
spark.admin.acls.groups mapr - Group of administrators.
spark.ui.view.acls mapruser1 - user who can be logged in to Spark master
and thriftserver UIs.
```

## Sqoop

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Apache Sqoop™ is a tool designed to efficiently transfer bulk data between Apache Hadoop and structured datastores, such as relational databases.

This documentation provides information for using Sqoop, but does not duplicate the Apache Sqoop™ documentation on the [Apache Sqoop website](#).

The following table describes the feature of [Sqoop1](#):

| Feature                                    | Sqoop1                                                                                                                                                                                                                                |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specialized connectors for all major RDBMS | Available.                                                                                                                                                                                                                            |
| Data transfer from RDBMS to Hive           | Done automatically.                                                                                                                                                                                                                   |
| Data transfer from Hive to RDBMS           | Must be done manually in two stages: <ol style="list-style-type: none"> <li>1. Extract data from Hive into filesystem, as a text file or as an Avro file.</li> <li>2. Export the output of step 1 to an RDBMS using Sqoop.</li> </ol> |
| Integrated Kerberos security               | Supported.                                                                                                                                                                                                                            |
| Password encryption                        | Not supported.                                                                                                                                                                                                                        |

### Sqoop1

**!** **Important:** This component is deprecated. HPE recommends using an alternate product. For more information, see [Discontinued Ecosystem Components](#) on page 5787.

Sqoop transfers data between the filesystem and relational databases. You can use Sqoop to transfer data from a relational database management system (RDBMS), such as MySQL or Oracle, into the filesystem and use MapReduce on the transferred data. Sqoop can export this transformed data back into an RDBMS.

The Maven repository contains JAR files for Sqoop that you can download and use for your application:

| Version     | Core  | EEP   | Maven Repository Locations               |
|-------------|-------|-------|------------------------------------------|
| Sqoop 1.4.7 | 6.2.x | 7.1.0 | <a href="#">1.4.7.0-mapr-710</a>         |
|             |       | 7.0.1 | <a href="#">1.4.7-mapr-701/</a>          |
|             |       | 7.0.0 | <a href="#">1.4.7-mapr-mep-7.x-2009/</a> |

For more information about Sqoop, see the [Apache Sqoop 1.4.7 Documentation](#).

## YARN

YARN is a resource-management and scheduling framework that distributes resource-management and job-management duties. YARN assigns the resource-management and job-management duties as follows:

- **ResourceManager:** manages cluster resources and tracks resource usage and node health.

- **ApplicationMaster:** a framework-specific process that negotiates resources for a single application (a single job or a directed acyclic graph of jobs), which runs in the first *container* allocated for the application.
- A YARN component called the **HistoryServer** archives job metrics and metadata. Status on completed applications is available via REST APIs.

The **ResourceManager** allocates resources among all the applications running the cluster. The **ResourceManager** includes a pluggable scheduler, which is responsible for allocating resources according to the resource requirements of the running applications. Current MapReduce schedulers, including the **Capacity Scheduler** and the **Fair Scheduler**, can be plugged into the YARN scheduler directly.

Label-based scheduling provides job placement control on a multi-tenant Hadoop cluster. Administrators can control exactly which nodes are chosen to run jobs submitted by different users and groups. An administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When users run jobs, they can place them on specified nodes on a per-job basis (using a job label) or on a per-queue level (using a queue label).

The **ResourceManager** caches the mapping file, and checks every two minutes (the default monitoring period) for updates. If the file has been modified, the **ResourceManager** updates the labels for all active **ApplicationMasters** immediately.

Each application runs an **ApplicationMaster** to negotiate resources from the **ResourceManager**. The **ApplicationMaster** works with the **NodeManagers** to execute and monitor tasks. The duties of the **ApplicationMaster** are divided as follows:

- **NodeManager:** One instance runs on each node, to manage that node's resources.
- **Container:** An abstraction representing a unit of resources on a node.

The **NodeManager** provides containers to an application. The **ResourceManager** and the **NodeManager** provide the system for distributed management of applications and resources.

### **ResourceManager**

Describes the role of the **ResourceManager**.

The **ResourceManager** is mainly concerned with arbitrating available resources in the cluster among competing applications, with the goal of maximum cluster utilization. The **ResourceManager** includes a pluggable scheduler called the **YarnScheduler**, which allows different policies for managing constraints such as capacity, fairness, and service level agreements.

The **ResourceManager** manages resources as follows:

- Each **NodeManager** takes instructions from the **ResourceManager**, reporting and handling containers on a single node
- Each **ApplicationMaster** requests resources from the **ResourceManager**, then works with containers provided by **NodeManagers**

The **ResourceManager** communicates with application clients via an interface called the **ClientService**. A client can submit or terminate an application and gain information about the scheduling queue or cluster statistics through the **ClientService**.

Administrative requests are served by a separate interface called the **AdminService**, through which operators can get updated information about cluster operation.

Behind the scenes, the **ResourceTrackerService** receives node heartbeats from the **NodeManager** to track new or decommissioned nodes. The **NMLivelinessMonitor** and **NodesListManager** keep an updated status of which nodes are healthy so that the scheduler and the **ResourceTrackerService** can allocate work appropriately.

A component called the `ApplicationMasterService` manages `ApplicationMasters` on all nodes, keeping the scheduler informed. A component called the `AMLivelinessMonitor` keeps a list of `ApplicationMasters` and their last heartbeat times, in order to let the `ResourceManager` know what applications are healthy on the cluster. Any `ApplicationMaster` that does not heartbeat within a certain interval is marked as dead and re-scheduled to run on a new container.

At the core of the `ResourceManager` is an interface called the `ApplicationsManager`, which maintains a list of applications that have been submitted, are running, or are completed. The `ApplicationsManager` accepts job submissions, negotiates the first container for an application (in which the `ApplicationMaster` will run) and restarts the `ApplicationMaster` if it fails.

The `ResourceManager` and `NodeManagers` communicate via heartbeats.

Configure the `ResourceManager` for high availability so that the failure of the `ResourceManager` service is a not single point of failure for the cluster. High availability of the `ResourceManager` is configured by default when you run `configure.sh` without specifying the `-RM` parameter.

### **ApplicationMaster**

Describes the role of the `ApplicationMaster`.

The `ApplicationMaster` is an instance of a framework-specific library that negotiates resources from the `ResourceManager` and works with the `NodeManager` to execute and monitor the granted resources (bundled as containers) for a given application. An application can be a process or set of processes, a service, or a description of work.

The `ApplicationMaster` is run in a container like any other application. The `ApplicationsManager`, part of the `ResourceManager`, negotiates for the container in which an application's `ApplicationMaster` runs when the application is scheduled by the `YarnScheduler`.

While an application is running, the `ApplicationMaster` manages the following:

- Application life cycle
- Dynamic adjustments to resource consumption
- Execution flow
- Faults
- Providing status and metrics

The `ApplicationMaster` is designed to support a specific framework, and can be written in any language since its communication with the `NodeManagers` and the `ResourceManager` is accomplished using extensible communication protocols. The `ApplicationMaster` can be customized to extend the framework or run any other code. For this reason, the `ApplicationMaster` is not considered trustworthy, and is not run as a trusted service.

An `ApplicationMaster` typically requests resources on multiple nodes to complete a job by sending the `ResourceManager` requests that include locality preferences and attributes of the containers. When the `ResourceManager` is able to allocate a resource to the `ApplicationMaster`, it generates a lease that the `ApplicationMaster` pulls on a subsequent heartbeat. A security token associated with the lease guarantees its authenticity when the `ApplicationManager` presents the lease to the `NodeManager` to gain access to the container.

The `Application Master` heartbeats to the `ResourceManager` to communicate its changing resource needs, and to let the `ResourceManager` know it is still alive. In response, the `ResourceManager` can return a lease on additional containers on other nodes, or cancel the lease on some containers. The `ApplicationMaster` can then adjust its execution strategy to fit the increase or decrease in available resources. When cluster resources become scarce, the `ResourceManager` can also request that the `ApplicationMaster` relinquish some resources. The `ApplicationMaster` can move work to other running containers in order to give up resources gracefully.

## Containers

A YARN container is a result of a successful resource allocation, meaning that the ResourceManager has granted an application a lease to use a specific set of resources in certain amounts on a specific node. The ApplicationMaster presents the lease to the NodeManager on the node where the container has been allocated, thereby gaining access to the resources.

To launch the container, the ApplicationMaster must provide a container launch context (CLC) that includes the following information:

- Environment variables
- Dependencies (local resources such as data files or shared objects needed prior to launch)
- Security tokens
- The command necessary to create the process the application plans to launch

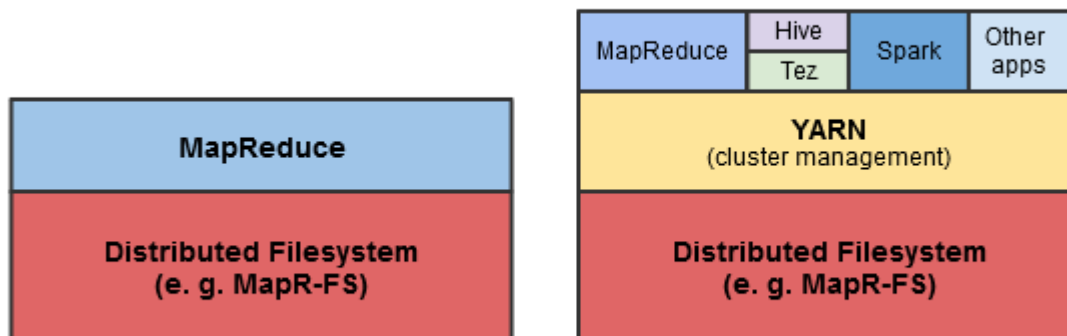

The CLC makes it possible for the ApplicationMaster to use containers to run a variety of different kinds of work, from simple shell scripts to applications to virtual machines.

## MapReduce Version 2

Provides an overview of how MapReduce works.

YARN dynamically allocates resources for applications as they execute. The MapReduce version 1 (MRv1) has been rewritten to run as an application on top of YARN; this new version is called MapReduce version 2.0 (MRv2).

Figure 2. A comparison between MapReduce 1.0 and MapReduce 2.0

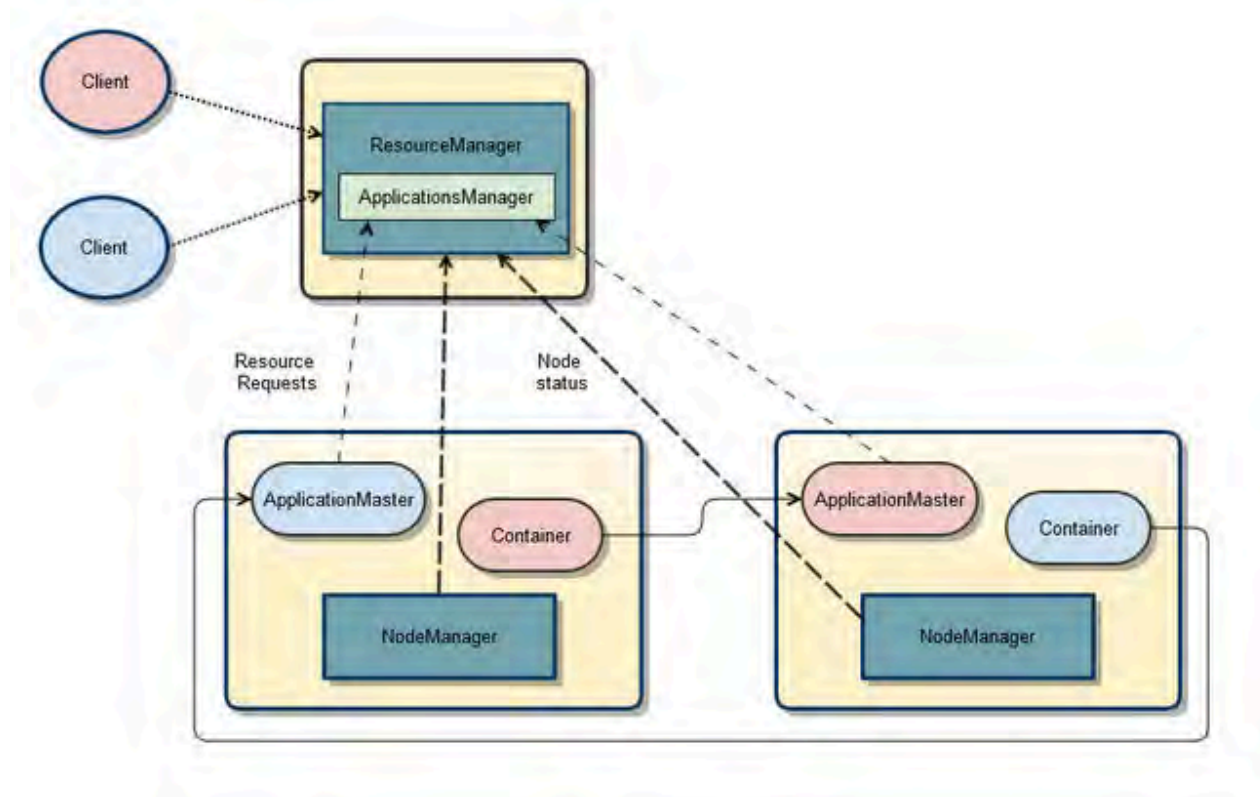

The main advancement in YARN architecture is the separation of resource management and job management, which were both handled by the same process (the JobTracker) in Hadoop 1.x. Cluster resources and job scheduling are managed by the ResourceManager, while resource negotiation and job monitoring are managed by an ApplicationMaster for each application running on the cluster. In MapReduce, each node advertises a relatively fixed number of map slots and reduce slots. This can lead to resource under-utilization, for example, when there is a heavy reduce load and map slots are available, because the map slots cannot accept reduce tasks (and vice versa).

YARN generalizes resource management for use by new engines and frameworks, allowing resources to be allocated and reallocated for different concurrent applications sharing a cluster. Existing MapReduce applications can run on YARN without any changes. At the same time, because MapReduce is now merely another application on YARN, MapReduce is free to evolve independently of the resource management infrastructure.

## How Applications Work in YARN

Describes the data flow during application execution in YARN.

The following diagram and steps describe how data flows during application execution in YARN.

The following steps summarize execution of the application:

1. A client submits an application to the YARN Resource Manager, including the information required for the Container Life Cycle (CLC).
2. The ApplicationsManager (in the Resource Manager) negotiates a container and bootstraps the ApplicationMaster instance for the application.
3. The ApplicationMaster registers with the Resource Manager and requests containers.
4. The ApplicationMaster communicates with NodeManagers to launch the containers it has been granted, specifying the CLC for each container.
5. The ApplicationMaster manages application execution. During execution, the application provides progress and status information to the ApplicationMaster. The client can monitor the application's status by querying the Resource Manager or by communicating directly with the ApplicationMaster.
6. The ApplicationMaster reports completion of the application to the Resource Manager.
7. The ApplicationMaster deregisters with the Resource Manager, which then cleans up the ApplicationMaster container.

## Direct Shuffle on YARN

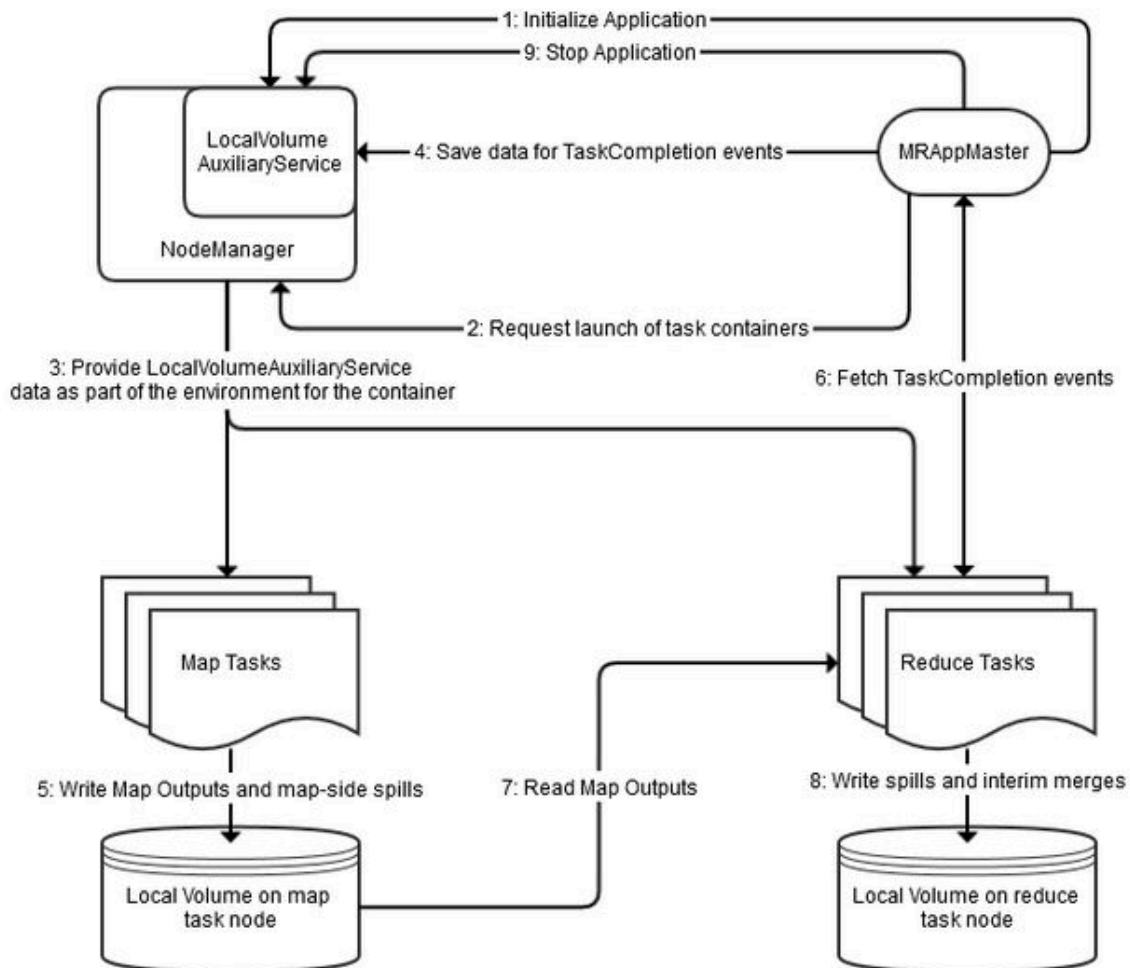

Explains the shuffle phase of a MapReduce application.

## Overview of Direct Shuffle

During the shuffle phase of a MapReduce application, HPE Ezmeral Data Fabric writes to a filesystem volume limited by its topology to the local node instead of writing intermediate data to local disks controlled by the operating system. This improves performance and reduces demand on local disk space while making the output available cluster-wide.

Direct Shuffle is the default shuffle mechanism for HPE Ezmeral Data Fabric. However, you can modify the `yarn-site.xml` and `mapred-site.xml` configuration files to enable Apache Shuffle for MapReduce applications. See [Apache Shuffle on YARN](#).

The `LocalVolumeAuxiliaryService` runs in the `NodeManager` process. The `LocalVolumeAuxiliaryService` manages the local volume on each node and cleans up shuffle data after a MapReduce application has finished executing.

1. The MRAppMaster service initializes the application by calling `initializeApplication()` on the LocalVolumeAuxiliaryService.
2. The MRAppMaster service requests task containers from the ResourceManager. The ResourceManager sends the MRAppMaster information that MRAppMaster uses to request containers from the NodeManager.
3. The NodeManager on each node launches containers using information about the node's local volume from the LocalVolumeAuxiliaryService.

4. Data from map tasks is saved in MRAppMaster for later use in TaskCompletion events, which are requested by reduce tasks.
5. As map tasks complete, map outputs and map-side spills are written to the local volumes on the map task nodes, generating Task Completion events.
6. ReduceTasks fetch Task Completion events from the Application Manager. The task Completion events include information on the location of map output data, enabling reduce tasks to copy data from MapOutput locations.
7. Reduce tasks read the map output information.
8. Spills and interim merges are written to local volumes on the reduce task nodes.
9. MRAppMaster calls `stopApplication()` on the `LocalVolumeAuxiliaryService` to clean up data on the local volume.

### Configuration for Direct Shuffle

The default YARN parameters for Direct Shuffle are as follows:

```
<property>
 <name>yarn.nodemanager.aux-services</name>
 <value>mapreduce_shuffle,mapr_direct_shuffle</value>
 <description>shuffle service that needs to be set for Map Reduce to
run</description>
</property>
<property>
 <name>yarn.nodemanager.aux-services.mapr_direct_shuffle.class</name>
 <value>org.apache.hadoop.mapred.LocalVolumeAuxService</value>
</property>
```

The default mapred parameters for Direct Shuffle are as follows:

```
<property>
 <name>mapreduce.job.shuffle.provider.services</name>
 <value>mapr_direct_shuffle</value>
</property>
<property>
 <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
 <value>org.apache.hadoop.mapreduce.task.reduce.DirectShuffle</value>
</property>
<property>
 <name>mapreduce.job.map.output.collector.class</name>
 <value>org.apache.hadoop.mapred.MapRFsOutputBuffer</value>
</property>
<property>
 <name>mapred.ifile.outputstream</name>
 <value>org.apache.hadoop.mapred.MapRIFileOutputStream</value>
</property>
<property>
 <name>mapred.ifile.inputstream</name>
 <value>org.apache.hadoop.mapred.MapRIFileInputStream</value>
</property>
<property>
 <name>mapred.local.mapoutput</name>
 <value>>false</value>
</property>
<property>
 <name>mapreduce.task.local.output.class</name>
```

```
<value>org.apache.hadoop.mapred.MapRFsOutputFile</value>
</property>
```

### Apache Shuffle on YARN

You can disable Direct Shuffle and enable Apache Shuffle by modifying the configuration options in the `yarn-site.xml` and `mapred-site.xml` files. This page describes how to configure Apache Shuffle for MapReduce applications.

The shuffling phase in Hadoop is the process of transferring mappers intermediate output to the reducers. Direct shuffle increases the load on filesystem disks. You can enable the Apache Shuffle to reduce the load on filesystem disks.

### Configuration for Apache Shuffle

Add the following property to `yarn-site.xml` file:

```
<property>
 <name>yarn.nodemanager.aux-services</name>
 <value>mapreduce_shuffle</value>
</property>
```

Add the following properties to `mapred-site.xml` file:

```
<property>
 <name>mapreduce.job.shuffle.provider.services</name>
 <value>mapreduce_shuffle</value>
</property>
<property>
 <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
 <value>org.apache.hadoop.mapreduce.task.reduce.Shuffle</value>
</property>
<property>
 <name>mapreduce.job.map.output.collector.class</name>
 <value>org.apache.hadoop.mapred.MapTask$MapOutputBuffer</value>
</property>
<property>
 <name>mapred.ifile.outputstream</name>
 <value>org.apache.hadoop.mapred.IFileOutputStream</value>
</property>
<property>
 <name>mapred.ifile.inputstream</name>
 <value>org.apache.hadoop.mapred.IFileInputStream</value>
</property>
<property>
 <name>mapred.local.mapoutput</name>
 <value>>true</value>
</property>
<property>
 <name>mapreduce.task.local.output.class</name>
 <value>org.apache.hadoop.mapred.YarnOutputFiles</value>
</property>
```

### Logging Options on YARN

Describes the logging options that are available on YARN.

For YARN applications, there are various logging options to choose from based on the data-fabric version and the types of applications that you run. In 4.0.2 and later versions, you have the following logging options:

- For MapReduce version 2 (MRv2) applications, the default logging option is to log files on the local filesystem. However, central logging and YARN log aggregation are also available.
- For non-MapReduce applications, the default logging option is to log files on the local filesystem. However, YARN log aggregation is also available.

### Centralized Logging for MRv2

Centralized logging provides an application-centric view of all the log files generated by NodeManager nodes throughout the cluster. It enables users to gain a complete picture of application execution by having all the logs available in a single directory, without having to navigate from node to node.

The MapReduce program generates three types of log output:

- Standard output stream: captured in the `stdout` file
- Standard error stream: captured in the `stderr` file
- Log4j logs: captured in the `syslog` file

Centralized logs are available cluster-wide as they are written to the following local volume on the data-fabric filesystem: /

```
var/mapr/local/<NodeManager node>/
logs/yarn/userlogs
```

Since the log files are stored in a local volume directory that is associated with each NodeManager node, you run the `maprccli job linklogs` command to create symbolic links for all the logs in a single directory. You can then use tools such as `grep` and `awk` to analyze them from an NFS mount point. You can also view the entire set of logs for a particular application using the HistoryServer UI.

### YARN Log Aggregation

The YARN log aggregation option aggregates logs from the local filesystem and moves log files for completed applications from the local filesystem to the data-fabric filesystem. This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

### Support for ADLS

Starting with MapR 6.1, you can use Azure Data Lake Store (ADLS) as a data source or destination for all applications.

#### Prerequisites for Using ADLS

Setting up Azure Data Lake Store (ADLS) on the Azure portal enables you to access ADLS from any application.

- Create an account on the [Azure portal](#).
- Create an Azure Data Lake Store ([get started with Azure Data Lake Storage](#)).

#### Authenticating ADLS Account

To access data stored in Azure Data Lake Store (ADLS), you must first authenticate your ADLS account using your ADLS credentials.

1. Obtain the following properties from your Azure application:

- `dfs.adls.oauth2.access.token.provider.type`  
ClientCredential, Refresh Tokens, or Client Keys to obtain the authentication type.
- `dfs.adls.oauth2.client.id`  
Create an Azure Active Directory application and get your application ID and authentication key.
- `dfs.adls.oauth2.refresh.url`  
Navigate to Azure Active Directory and click on Endpoints. Use the OAUTH 2.0 TOKEN ENDPOINT value.
- `dfs.adls.oauth2.credential`  
Obtain the access token key value from App Registrations in your Azure account.

2. Add the properties obtained in step 1 to the `core-site.xml` file:

```
<!--ADL-->
<property>
 <name>dfs.adls.oauth2.access.token.provider.type</name>
 <value>ClientCredential</value>
</property>

<property>
 <name>dfs.adls.oauth2.client.id</name>
 <value>f377fab9-c0a3-4531-alc9-77345105</value>
</property>

<property>
 <name>dfs.adls.oauth2.refresh.url</name>
 <value>https://login.microsoftonline.com/25735fb/oauth2/token</
value>
</property>

<property>
 <name>dfs.adls.oauth2.credential</name>
 <value>WTkn4xS0ISSqyzo4R6bu/OW2oPyGNMzWRw/d2z2CGiw=</value>
</property>
```

**Note:** The `core-site.xml` file can be overwritten using the command line. You can also specify these properties at runtime. The syntax for overwriting ADLS properties at runtime using the command line is as follows:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
-Ddfs.adls.oauth2.access.token.provider.type=ClientCredential
-Ddfs.adls.oauth2.client.id=f377fab9-c0a3-4531-alc9-77345105
-Ddfs.adls.oauth2.refresh.url=https://login.microsoftonline.com/
25735fb/oauth2/token
-Ddfs.adls.oauth2.credential=WTkn4xS0ISSqyzo4R6bu/OW2oPyGNMzWRw/
d2z2CGiw= adl://testhue.azuredatalakestore.net/some_folder/testfile
adl://testhue.azuredatalakestore.net/some_folder/wordcountout
```

To provide your ADLS credentials securely, see [Securely Providing ADLS Credentials](#) on page 4369.

3. Provide your application with file access.

- For secure clusters, MapR-SASL (Simple Authentication and Security Layer), and Kerberos, import the required CA certificate.

- [Open source documentation](#)
- [Azure documentation](#)
- [Azure documentation on authorization and access control](#)
- 

### *Securely Providing ADLS Credentials*

You can provide your ADLS credentials securely by hiding the open, readable configuration on the command line using the Hadoop credential provider.

- Generate a `jceks` file for ADLS authorization:

```
hadoop credential create dfs.adls.oauth2.client.id -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client ID
hadoop credential create dfs.adls.oauth2.credential -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client secret
hadoop credential create dfs.adls.oauth2.refresh.url -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value refresh URL
```

- Run the `DistCp` example using the `jceks` file:

```
hadoop distcp
[-D hadoop.security.credential.provider.path=localjceks://hdfs/user/
USER_NAME/adlskeyfile.jceks]
hdfs://<NameNode Hostname>:9001/user/foo/007020615
adl://<Account Name>.azuredatalakestore.net/testDir/
```

- Configure the `core-site.xml` file to use the `jceks` file:

```
<property>
 <name>hadoop.security.credential.provider.path</name>
 <value>localjceks://hdfs/user/USER_NAME/adlskeyfile.jceks</value>
 <description>Path to interrogate for protected credentials.</
description>
</property>
```

### *Using ADLS for Data Input or Output*

You can use Azure Data Lake Store (ADLS) as a source or destination for your application data.

For general information about the features of ADLS, refer to the [Azure Data Lake Store documentation](#).

For information about configuring ADLS as storage for a Hadoop cluster, refer to the official [Apache documentation](#).

The Azure Data Lake Storage access path syntax is:

```
adl://<Account Name>.azuredatalakestore.net/
```

You can use ADLS the same way as you use filesystem, substituting an adl scheme instead of maprfs, hdfs, webhdfs, and so on.

### 1. Create a directory and read data:

```
[mapr@node4 ~]$ hadoop fs -mkdir adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/

Found 1 items
drwxr-xr-x - 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:09
adl://<username>.azuredatalakestore.net/testdir
```

### 2. Put data into ADLS from your local filesystem:

```
[mapr@node4 ~]$ hadoop fs -put testfile adl://
<username>.azuredatalakestore.net/testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
testdir

Found 1 itemsrw-rr- 1 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:10
adl://<username>.azuredatalakestore.net/testdir/testfile
```

### 3. Delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

### 4. Run YARN jobs with your input and output stored in ADLS:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
adl://<username>.azuredatalakestore.net/testdir/testfile adl://
<username>.azuredatalakestore.net/wordcountout
```

## Deleting Data from ADLS

You can delete your data from Azure Data Lake Store (ADLS).

- To delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

## Maven and the HPE Ezmeral Data Fabric

This section discusses topics associated with Maven and the HPE Ezmeral Data Fabric.

## Maven Artifacts for the HPE Ezmeral Data Fabric

Maven artifacts can be used for dependency management when developing applications based on the the HPE Ezmeral Data Fabric.

You can access the data-fabric Maven repository by browsing [Nexus](#) or as follows:

```
<repositories>
 <repository> <id>mapr-releases</id>
 <url>https://repository.mapr.com/maven/</url>
 <snapshots><enabled>>false</enabled></snapshots>
 <releases><enabled>>true</enabled></releases>
 </repository>
</repositories>
```

**Maven Artifacts for EEP 7.1.1**

Maven artifacts for EEP 7.1.1 are unchanged from the Maven artifacts for EEP 7.1.0.

See [Maven Artifacts for EEP 7.1.0](#) on page 4435.

**Maven Artifacts for EEP 7.1.0**

Listed are all Maven artifacts for EEP 7.1.0 components.
