## Integrating the MapR GitHub and Maven Repositories

This topic provides instructions for cloning the GitHub and Maven repositories for a MapR open source project into your Eclipse IDE.

### Integrating Git

1. Open the Git Repository perspective by selecting **Window>Open Perspective>Other...** then choosing **Git Repository Exploring**.

- From the Git Repository perspective, click the  button to display the **Clone Git Repository** dialog.

- From a web browser, navigate to the MapR [repository](#), then select the project you want to clone.

- Copy the git URI from the project page to your clipboard by clicking the  button.
- In the **Clone Git Repository** dialog, paste the git URI into the **URI:** field, then click **Next**. Eclipse will connect to github and download the repository metadata, then display a list of branches.
- Select the branches you wish to clone, then click **Next**.
- Configure the destination directory, then click **Finish**. Eclipse downloads the project from github and adds it to your view.

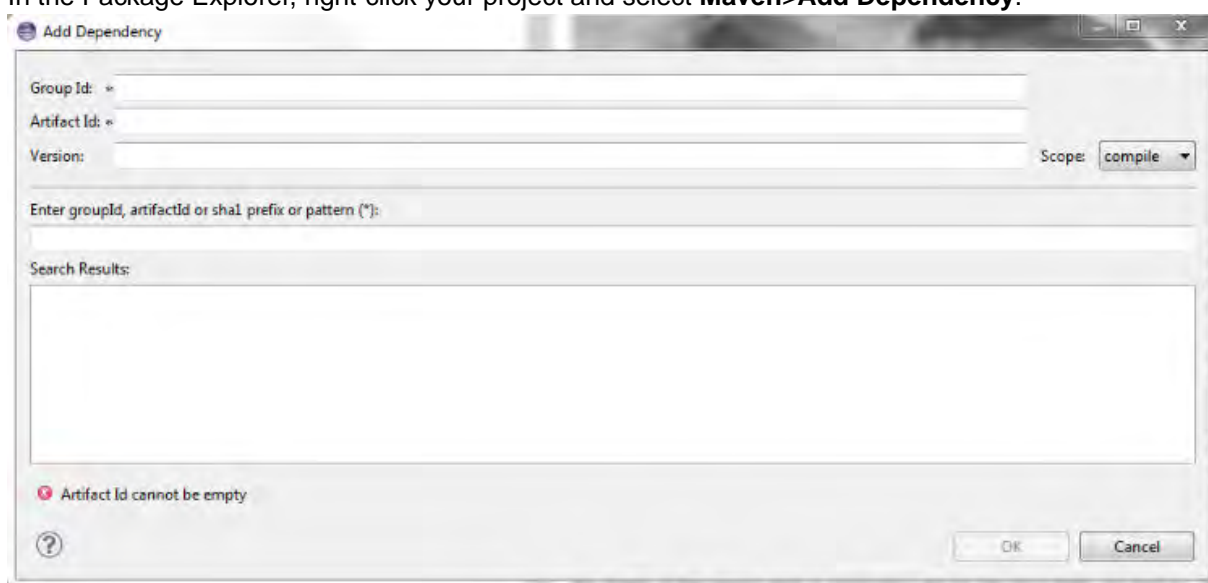

### Integrating Maven

- Start a new Maven project, or convert your current project into a Maven project if necessary.

2. Select **Window>Show View>Package Explorer** to show your current Maven project.
3. Add the following lines to your project's `pom.xml` file:

```
<repositories>
 <repository>
 <id>mapr-releases</id>
 <url>https://repository.mapr.com/maven/</url>
 <snapshots><enabled>false</enabled></snapshots>
 <releases><enabled>true</enabled></releases>
 </repository>
</repositories>
```

4. In a browser, navigate to the MapR [Maven Repository](#) and search for the Maven artifact your project depends on. You can also [browse](#) the repository.
5. In the Package Explorer, right-click your project and select **Maven>Add Dependency**.

6. Enter the `groupId`, `artifactId`, and `version` values for the dependency, then click **OK**.
7. Refresh the workspace by pressing F5. Your Maven dependencies download automatically.

## Developer's Reference

---

This section contains in-depth information for the developer.

### HPE Ezmeral Data Fabric Database Shell (JSON Tables)

The `mapr dbshell` is a tool that enables you to create and perform basic manipulation of JSON tables and documents. You run `dbshell` by typing `mapr dbshell` on the command line after logging into a node in a HPE Ezmeral Data Fabric cluster.

**Note:** HPE Ezmeral Data Fabric Database Shell does not support HPE Ezmeral Data Fabric Event Streams streams operations.

## Permissions

Before running dbshell, your user ID must have both the `readAce` and `writeAce` permissions on the volume. For information about these permissions, see [Managing Whole Volume ACEs](#) on page 1575.

## SUSE Linux Error Messages

When you run dbshell on SUSE Linux, you might see the following messages:

```
[INFO] Unable to bind key for unsupported operation: backward-delete-word
[INFO] Unable to bind key for unsupported operation: up-history
[INFO] Unable to bind key for unsupported operation: down-history
```

To suppress these messages, edit the `/etc/inputrc` file and rename the keywords as follows:

| Original name        | New name           |
|----------------------|--------------------|
| backward-delete-word | backward-kill-word |
| down-history         | next-history       |
| up-history           | previous-history   |

## Command Descriptions

To get a list of supported dbshell commands, run `help` at the shell prompt:

```
* ! - Allows execution of operating system (OS) commands
* // - Inline comment markers (start of line only)
* ; - Inline comment markers (start of line only)
* cat - Print the content of the specified file on the standard output
* cd - Change the current directory to the specified path.
* clear - Clears the console
* cls - Clears the console
* create - Create a json table at the given path.
* date - Displays the local date and time
* debug - Sets/shows the debug mode.
* delete - Delete a document from the table.
* desc - Describes the properties of a table.
* drop - Deletes a MapR-DB json table.
* exists - Returns true if the table exists.
* exit - Exits the shell
* find - Retrieves one or more documents from the table.
* findbyid - Retrieves a single document from the table.
* help - List all commands usage
* indexlist - Retrieves the list of indexes for the specified table.
* indexscan - Scan the index and return the document in their natural order.
* insert - Inserts or replaces a document into the table.
* jsonoptions - Sets/shows the Json output options.
* list - Lists all tables in a folder or matching the specified pattern.
* ls - Lists files and folders.
* mkdir - Create a directory at the specified path.
* pwd - Print the absolute path of the current working directory.
* quit - Exits the shell
* replace - Replace a document based on condition.
* script - Parses the specified resource file and executes its commands
* system properties - Shows the shell's properties
* tableoptions - Sets/shows the MapR-DB Table access options.
* update - Update field in a single document.
* version - Displays shell version
* whoami - Prints the current MapR-DB Shell user.
```

## Parameters

Various components of these commands will be either be in JSON (in case a list of key-value is required) or a single value following a switch identifying the component.

To get a list of parameters for a specific command, run `help <command>` at the prompt. For example: `help find` returns the following:

```
maprdb root:> help find
Command: find
Description: Retrieves one or more documents from the table.
Options:
 *, --t, --table Table path. [required]
 --id Document Id.
 --fromid Document Id to start from (inclusive)
 --toid Document Id to stop at (exclusive)
 --limit Maximum number of documents to return.
 --withtags, --withTags Enables/disables printing with extended Type
Tags.
 --pretty Enables/disables pretty printing of the document.
 --offset Skip first n number of rows in the result.
 --orderby Sort result by the given fields.
 --c, --where Condition in JSON format
 --f, --fields Projections in JSON documents
 --q, --query Query in JSON documents
Examples:
 find /tables/users
 find /tables/users --fromid user001 --toid user00a --limit 32
```

## Value Types

Extended type values are shown using type tags. The scalar types are represented as follows:

- {"\$binary":"AAAASw=="}
- {"\$numberLong":21491}
- {"\$numeric":47.92}
- {"\$time":"14:35:28.981"}
- {"\$date":"2017-04-24T22:35:28.981Z"}
- {"\$dateDay":"2017-04-23"}

## Bulk Operations

Currently, bulk conditional operations are not supported.

### dbshell create

Describes how to use HPE Ezmeral Data Fabric Database shell to create a JSON table.

## Description

To create JSON tables, run the `create <table path>` command.

When you create a JSON table using `mapr dbshell`, the default column family is created automatically. There are no commands for creating additional column families. To create column families, exit the shell and use the `maprcli table cf create` command.

**Note:** If you are using a 5.2.x dbshell client to connect to a 6.0 (or later) server, you must set the `insertionorder` table option to `false` before creating your table. The `insertionorder` option is not support as of 6.0. See the following example:

```
tableoptions --insertionorder false
```

Run `tableoptions` in dbshell to see the current setting of `insertionorder`.

### Parameters

| create Options                               | Description                                                                                                                                            |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--t, --table &lt;table path&gt;</code> | Table path<br><br>Although the <code>--t</code> and <code>--table</code> qualifiers are optional, you must specify a <code>&lt;table path&gt;</code> . |

### Syntax

```
create <table path>
```

### Example

In the following example, **data** is the volume name and **movies** is the new table name.

```
create /data/movies
```

### dbshell delete

#### Description

The dbshell `delete` command deletes a single JSON document. To delete a document, specify the path of the table where the document is located, the ID of the document, and an optional condition. If the condition for the specified document evaluates to true, the document is deleted.

### Parameters

| delete Options                             | Description                                                                                                                                                                           |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>*, --t, --table</code><br>(Required) | Table path                                                                                                                                                                            |
| <code>--id</code><br>(Required)            | ID of the document to delete<br><br><b>Note:</b> You can specify this parameter only once.                                                                                            |
| <code>--c, --where</code>                  | OJAI condition, in JSON format<br><br>The condition must qualify to perform the delete. See <a href="#">OJAI Query Condition Syntax</a> on page 2882 for a description of the syntax. |

### Syntax

```
delete <table path> --id <row-key> --c <condition>
```

**Example: Delete a Document if a Condition is Met**

The following example deletes the document with the `_id` `id1`, if the condition `(a.b[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1))` is met:

```
delete /tbl --id id1
 --c {
 "$and": [
 {"$eq": {"a.b[0].boolean": false}},
 {"$or": [
 {"$ne": {"a.c.d": 5}},
 {"$gt": {"a.b[1].decimal": 1}}
]}
]}
 }
```

**Example: Delete a Document**

The following example deletes a document with `_id` `movie0000002` from the `movies` table:

```
delete /data/movies --id movie0000002
```

**dbshell drop****Description**

To run the `drop` command, specify the path to the HPE Ezmeral Data Fabric Database JSON table.

**Parameters****Table**

| drop Options                                                           | Description |
|------------------------------------------------------------------------|-------------|
| <code>*</code> , <code>--t</code> , <code>--table</code><br>(Required) | Table path  |

**Syntax**

```
drop <table path>
```

**Example**

```
drop /data/movies
```

**dbshell find or findbyid**

To query JSON documents in HPE Ezmeral Data Fabric Database shell, use either the `find` or `findbyid` command. The `find` command enables you to scan complete tables and retrieve rows that satisfy projection and/or condition clauses. The `findbyid` command enables you to retrieve a single document with a given ID.

When you review the `find` examples, note that they are sometimes shown split across multiple lines for readability. You must enter the commands on a single line when you run them in `dbshell`.

 **Note:** If your `find` query requires the [OJAI Distributed Query Service](#) on page 467, you must install the `mapr-drill-internal` package on the nodes where you run `dbshell`. The package is available in the MapR repository from which you download Ezmeral Ecosystem Packs. See [Data Fabric Repositories and Packages](#) on page 87 for details.

### Syntax

```
find <table path> <options>
```

```
findbyid <table path> --id <key-row ID>
```

### Parameters

| find Options                                                           | findbyid Options                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>*</code> , <code>--t</code> , <code>--table</code><br>(Required) | <code>*</code> , <code>--t</code> , <code>--table</code><br>(Required) | Table path                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>--id</code>                                                      | <code>--id</code><br>(Required)                                        | Document ID<br>For conditions on a single document ID, you can provide the ID either by using the <code>--id</code> switch or by specifying the ID in a condition payload.<br>For example, <code>--id id1</code> is equivalent to <code>--c {"\$eq": {"_id": "id1"}}</code> .<br> <b>Note:</b> You cannot specify multiple IDs using either syntax. |
| <code>--fromid</code>                                                  | n/a                                                                    | Document ID to start from (inclusive)                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>--toid</code>                                                    | n/a                                                                    | Document ID to stop at (exclusive)                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>--limit</code>                                                   | n/a                                                                    | Maximum number of documents to return                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>--withtags</code> , <code>--withTags</code>                      | <code>--withtags</code> , <code>--withTags</code>                      | Enables or disables printing with extended type tags<br>Value: <code>True False</code><br>Default: <code>True</code>                                                                                                                                                                                                                                                                                                                  |
| <code>--pretty</code>                                                  | <code>--pretty</code>                                                  | Enables or disables pretty printing of documents<br>Value: <code>True False</code><br>Default: <code>True</code>                                                                                                                                                                                                                                                                                                                      |
| <code>--offset</code>                                                  | n/a                                                                    | Omits the first n number of documents in the result                                                                                                                                                                                                                                                                                                                                                                                   |

| find Options  | findbyid Options | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| find Options | findbyid Options | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --q, --query | n/a              | <p>Query JSON documents</p> <p>This option accepts a query string in JSON format with predefined keywords that define the behavior of the query.</p> <p>The following examples shows a query that uses three keywords:</p> <pre>find table/test --q {     "\$select": "a",     "\$limit": 2,     "\$offset": 1 }</pre> <p> <b>Note:</b> The <code>find</code> command does not allow <code>--query</code> to work with other options, such as <code>--fields</code>, <code>--where</code>, and <code>--orderby</code>. For example, the following command ignores the <code>--f</code> option:</p> <pre>find table/test --f "a" --q {"\$limit": 2}</pre> <p>In addition, you should not enter the same keyword twice:</p> <pre>// Incorrect {"\$select": "a", "\$select": "b"}</pre> <pre>// Correct {"\$select": ["a", "b"]}</pre> <p>See <a href="#">Query with --query</a> on page 5495 for more examples.</p> |

### Query with --query

When querying JSON documents with the `find` command, you can use OJAI query syntax with the `--query` option. With this option, you can specify keywords that determine the documents and the fields from those documents that the command returns.

### Syntax

```
find <table path> --query <keywords>
```

**Note:** The `find` command does not allow `--query` to work in tandem with other options such as `--fields`, `--where`, and `--orderby`.

For example, the following command does not return your desired results:

```
find /tbl --f a --q {"$limit": 2}
```

In addition, repetition of keywords in the `--query` option is not supported. You should not enter the same keyword twice:

```
// Incorrect
{"$select": "a", "$select": "b"}
```

```
// Correct
{"$select":["a","b"]}
```

### Keywords for the --query Option

The --query option supports the following keywords:

| --query Keywords | Equivalent find Option                 |
|------------------|----------------------------------------|
| \$select         | Equivalent to the --f, --fields option |
| \$where          | Equivalent to the --c, --where option  |
| \$limit          | Equivalent to the --limit option       |
| \$offset         | Equivalent to the --offset option      |
| \$orderby        | Equivalent to the --orderby option     |
| \$options        | No equivalent option                   |

The following sections provide examples of each keyword. For more details, see [OJAI Query Syntax](#) on page 2879.

### Sample JSON Document

The examples in this topic use the following sample JSON document:

```
{
 "_id": "id1",
 "a": {
 "b": [{"boolean":false}, {"decimal": 123.456}],
 "c": {
 "d":10,
 "e": "Hello"
 }
 },
 "m": "MapR wins"
}
```

### \$select Syntax and Example

The \$select keyword defines the field path projections to be displayed in the result set.

The following syntax shows single and multiple field path projections:

```
// Single field path projection syntax
find <table path> --q {"$select": "<fieldpath>"}

// Multiple field path projection syntax
find <table path> --q {"$select":
["<fieldpath1>","<fieldpath2>","<fieldpath3>"]}
```

The following examples show single and multiple field path projections:

```
// Single field path projection example
find /tbl --q {"$select": "a.c.d"}

// Multiple field path projection example
find /tbl --q {"$select": ["a.c.d", "a.c.e", "m"]}
```

See [OJAI Query Projection](#) on page 2880 for more information about \$select.

## \$where Syntax and Example

When using the `$where` keyword, define the condition using [OJAI Query Condition Syntax](#) on page 2882.

```
find <table path> --q {"$where":<condition>}
```

The following example performs a `find` operation with a projection and a condition:

```
find /tbl --q {"$select":"a.c.e",
 "$where":{"$and":[{"$eq":{"a.b[0].boolean":false}},
 {"$or":[{"$ne":{"a.c.d":5}},
 {"$gt":{"a.b[1].decimal":1}},
 {"$lt":{"a.b[1].decimal":10}}]
 }
 }
}
```

The projection is on field `a.c.e`. The condition is the following expression:

```
(a.b[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

## \$limit Syntax and Example

The `$limit` keyword sets the maximum number of documents to return. It only accepts positive integers. It throws an exception for negative or decimal values.

```
find <table path> --q {"$limit":<positive integer>}
```

The following example performs a `find` with a projection on the `a.c.e` and `m` fields and limits the result set to a max of 10 documents:

```
find /tbl --q {"$select":["a.c.e","m"],
 "$limit":10
}
```

See [OJAI Query Limit](#) on page 2881 for more information about `$limit`.

## \$offset Syntax and Example

The `$offset` keyword skips the first `n` number of rows in the result. If `n` is greater than the total number of documents, no documents are returned. It only accepts positive integers.

```
find <table path> --q {"$offset":<positive integer>}
```

The following example performs a `find` operation with projection on the `a.c.e` and `m` fields and offsets the result set to skip first five documents:

```
find /tbl --q {"$select":["a.c.e","m"],
 "$offset":5
}
```

See [OJAI Query Offset](#) on page 2881 for more information about `$offset`.

## \$orderby Syntax and Examples

The \$orderby keyword sorts the result on the specified fields.

The following shows the syntax and example of sorting a single field in the default ascending order:

```
// Syntax for sorting a single field in the default ascending order
find <table path> --q {"$orderby":"<field path>"}

// Example sort on field path a.c.e in the default ascending order
find /tbl --q {"$orderby":"a.c.e"}
```

The following show the syntax and examples of sorting a single field in ascending or descending order where <order> is ASC for ascending and DESC for descending:

```
// Syntax for sorting a single field in ASC/DESC order
find <table path> --q {"$orderby":{"<field path>":"<order>"}}

// Example sort on field path a.c.e in ascending order
find /tbl --q {"$orderby":{"a.c.e":"asc"}}

// Example sort on field path a.c.e in descending order
find /tbl --q {"$orderby":{"a.c.e":"desc"}}
```

**Note:** The keywords ASC and DESC are case insensitive.

The following shows the syntax and an example of sorting multiple fields in ascending and descending order:

```
// Syntax for sorting multiple field paths in ascending/descending order
find <table path> --q {"$orderby":[{"<field path1>":"<order>"},
 {"<field path2>":"<order>"},
 {"<field path3>":"<order>"}
]}

// Example sort on field path a.c.d (in the default ascending order)
// and field path a.c.e in descending order
find /tbl --q {"$orderby":["a.c.d",{"a.c.e":"desc"}]}
```

See [OJAI Query Order By](#) on page 2881 for more information about \$orderby.

## \$options Syntax and Example

The \$options keyword enables you to influence a query's execution path. The general syntax is as follows:

```
find <table path> --q {"$options":{"<option name>:<option value>"}}
```

When specifying the <option name>, you must separate the components of the option name, replacing the dots with curly braces and colons and enclosing each component in quotes. The following example shows you how to do this for the `ojai.mapr.query.hint-using-index` option. The example forces the query to use a secondary index named `colIndex`:

```
find /apps/test --q {
 "$where":{"$eq":{"col":10}},
 "$options":{"ojai":{"mapr":{"query":{"hint-using-index":"colIndex"}}}}
}
```

See [OJAI Query Options](#) on page 2864 for a complete list of available query options.

### Query with --orderby

When querying JSON documents with the `find` command, you can use the `--orderby` option to order the data. You can specify either an ascending or descending sort using the keywords, `ASC` and `DESC`.

### General Syntax

```
find <table path> --orderby <field path>:<sortorder>
```

The keywords `ASC` and `DESC` are case insensitive. Ascending is the default sort order.

### Sample JSON Document

The following sample JSON document is used in examples in this section:

```
{
 "_id": "id1",
 "a": {
 "b": [{"boolean":false}, {"decimal": 123.456}],
 "c":{
 "d":10,
 "e":"Hello"
 }
 },
 "m": "MapR wins"
}
```

### Simple Sort

The following syntax and example are a simple sort on a single field path in the default ascending sort order:

```
// Syntax
find <table path> --orderby <field path>

// Example
find /tbl --orderby a.c.d
```

### Specific Sort on Single Field

The following syntax and example are a sort with a specified ordering on a single field path:

```
// Syntax
find <table path> --orderby <field path>:<sort order>

// Example
find /tbl --orderby a.c.d:desc
```

### Specific Sort on Multiple Fields

The following syntax and example specify a sort ordering on each field path:

```
// Syntax
find <table path> --orderby <field path>:<sort order>,<field path>:<sort order>

// Example
find /tbl --orderby a.c.d:asc,a.c.e:desc
```

### Mixed Mode Sort on Multiple Fields

The following syntax and example specify a sort ordering on one field path and use the default sort order (ascending) on another field path.

```
// Syntax
find <table path> --orderby <field path>:<sort order>,<field path>

// Example
find /tbl --orderby a.c.d:DESC,a.c.e
```

### Query Examples with Other Options

This section contains examples of `findbyid` and `find` commands using options not used in examples in other sections.

#### Return all Documents

When you do not specify other options to `find` except the table path, the command returns all documents. The following example returns all documents that are in the `/data/movies` table:

```
find /data/movies
```

#### Return Limited Number of Documents with Specified Range of IDs

The following example returns at most 32 documents within a range of IDs that includes the specified starting ID and excludes the specified ending ID:

```
find /data/movies --fromid movie0000001 --toid movie0000100 --limit
32
```

#### Return all Documents with Specified ID

The following example returns the document that has the specified ID:

```
findbyid /data/movies --id movie0000002
```

#### Return Documents Using Projection and Conditions

The following example performs a `find` operation with a projection and condition and limits the result to 10 documents:

```
find /tbl --c {
 "$and": [
 {"$eq": {"a.b[0].boolean": false}},
 {"$or": [
 {"$ne": {"a.c.d": 5}},
 {"$gt": {"a.b[1].decimal": 1}},
 {"$lt": {"a.b[1].decimal": 10}}
]}
]}
--fields m,a.c.e --limit 10
```

The projection is on fields on `m` and `a.c.e`. The condition is the following expression:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

## Returns Documents in Specified Order

The following example is identical to the previous one, except it also includes an ordering on the result:

```
find /tbl --c {
 "$and": [
 {"$eq": {"a.b[0].boolean": false}},
 {"$or": [
 {"$ne": {"a.c.d": 5}},
 {"$gt": {"a.b[1].decimal": 1}},
 {"$lt": {"a.b[1].decimal": 10}}
]}
]}
--fields m,a,c,e
--orderby m,a,c,e:desc
--limit 10
```

## dbshell indexscan

### Description

The `indexscan` command scans secondary indexes and returns the document ID and the values of the indexed and included fields. This includes displaying information about errors encountered inserting into the index.

### Syntax

```
maprdb root:> indexscan
 <table path>
 --indexname <index name>
 --limit
 --withtags
 --pretty
 --mode
 --where
 --fields
 --decodeindexedfields
```

### Parameters

| Parameters                                                             | Description                                                                     |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <code>*</code> , <code>--t</code> , <code>--table</code><br>(Required) | Path of the JSON table                                                          |
| <code>--indexname</code> , <code>--indexName</code><br>(Required)      | Name of the secondary index                                                     |
| <code>--limit</code>                                                   | Maximum number of documents to return                                           |
| <code>--withtags</code> , <code>--withTags</code>                      | Enables or disables printing with extended JSON type tags<br>Values: true false |
| <code>--pretty</code>                                                  | Enables or disables pretty printing of documents<br>Values: true false          |

| Parameters            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| --mode                | <p>Enables display of the error information for the index</p> <p>Value: <code>err</code></p> <p>If you specify <code>--mode err</code>, the command scans only rows with errors and prints the <code>_id</code> and <code>\$ERROR</code> fields. If you do not specify <code>--mode</code>, the command prints the <code>_id</code>, <code>indexed</code>, and <code>included</code> fields of rows that do not have errors.</p> <p>The following lists the types of errors:</p> <ul style="list-style-type: none"> <li>• <code>KEY_TOO_LONG</code></li> <li>• <code>INVALID_CAST</code></li> </ul> |
| --c, --where          | <p>Condition, in JSON format, that filters the rows returned</p> <p>See <a href="#">OJAI Query Condition Syntax</a> on page 2882 for a description of the syntax.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |
| --f, --fields         | <p>Fields from the index to return</p> <p>See <a href="#">JSON Document Field Paths</a> on page 478 for details about how to specify field paths.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| --decodeindexedfields | <p>Enables display of values for indexed fields that are nested documents or arrays</p> <p>Value: <code>true</code></p> <p> <b>Note:</b> This parameter ignores all other values, including specifying no value.</p>                                                                                                                                                                                                                                                                                             |

### Example: Simple Index

The following example uses a simple index where `index1` is on `table1`, field `a`.

```
// Insert one document
maprdb root:> insert /table1 --id 1 --value '{"a":7}'
Document with id: "1" inserted.

// Create index1 on table1 and index field a
maprcli table index add -path /table1 -index index1 -indexedfields a

// Perform a normal indexscan; the _id field and the indexed field for the
document is displayed
maprdb root:> indexscan /table1 --indexname index1
{"_id":"1","a":7}
1 document(s) found.

// Insert another document with _id value as 2 with field a as a map
maprdb root:> insert /table1 --id 2 --value '{"a":[1,2,3]}'

// Perform a normal indexscan; the document that does not have the error is
displayed
maprdb root:> indexscan /table1 --indexname index1
{"_id":"2","a":[1,2,3]}
{"_id":"1","a":7}
2 document(s) found.

// Perform an indexscan with error mode; no errors are displayed because
MapR-DB 6.1 allows
```

```
// you to create indexes on array fields
maprdb root:> indexscan /table1 --indexname index1 --mode err
0 document(s) found.
```

### Example: Composite Index

The following example uses a composite index with included fields, in which `index2` is on table `table1`, with indexed fields `a` and `b` and included field `c`.

```
// Insert a document with fields 'a', 'b' and 'c'.
maprdb root:> insert /table1 --id 2 --value '{"a":7,"b":"mapr","c":"db"}'
Document with id: "2" inserted.

// Create index2 on table1 with indexed fields a and b, and included field c
maprcli table index add -path /table1 -index index2 -indexedfields
a,b -includedfields c

// Perform an indexscan
maprdb root:> indexscan /table1 --indexname index2
{"_id":"2","c":"db","a":7,"b":"mapr"}
1 document(s) found.

// Insert a document that has field a as a map
maprdb root:> insert /table1 --id 1 --value '{"a":
{"m":4},"b":"mapr","c":"db"}'
Document with id: "1" inserted.

// Perform a normal indexscan
maprdb root:> indexscan /table1 --indexname index2
{"_id":"1","c":"db","a":{"m":4},"b":"mapr"}
{"_id":"2","c":"db","a":7,"b":"mapr"}
2 document(s) found.

// Perform an indexscan with error mode; no errors are displayed because
MapR-DB 6.1 allows
// you to create indexes on array fields
maprdb root:> indexscan /table1 --indexname index2 --mode err
0 document(s) found.
```

### Example: Index on Container Field Paths

Assume you have a table in the path `/apps/indexExample` with the following document:

```
{
 "_id": "10000",
 "FullName": {
 "LastName": "Smith",
 "FirstName": "John"
 },
 "Address": {
 "Street": "123 SE 22nd St.",
 "City": "Oakland",
 "State": "CA",
 "Zipcode": "94601-1001"
 },
 "Gender": "M",
 "AccountBalance": 999.99,
 "Email": "john.smith@company.com",
 "Phones": [
 {"Type": "Home", "Number": "555-555-1234"},
 {"Type": "Mobile", "Number": "555-555-5678"}
]
}
```

```

 {"Type": "Work", "Number": "555-555-9012"}
],
 "Hobbies": ["Baseball", "Cooking", "Reading"],
 "DateOfBirth": "10/1/1985"
}

```

The following example creates a composite index on the `Type` and `Number` subfields in the nested documents in the `Phones` array:

```

// Create idx3 on the table with indexed fields Phones[].Type and
Phones[].Number
maprcli table index add -path /apps/indexExample -index idx3 \
 -indexedfields Phones[].Type,Phones[].Number

// Perform an indexscan WITHOUT the decodeindexedfields parameter.
// Three rows are returned, one for each element in the Phones[] array.
// The output contains no values for the indexed fields.
maprdb root:> indexscan /apps/indexExample --indexname idx3
{"_id":"10000"}
{"_id":"10000"}
{"_id":"10000"}
3 document(s) found

// Perform an indexscan WITH the decodeindexedfields parameter set to true.
// The output includes the values in the indexed fields.
maprdb mapr:> indexscan /apps/indexExample --indexname
idx3 --decodeindexedfields true
{"_id":"10000", "$idx":["Home", "555-555-1234"]}
{"_id":"10000", "$idx":["Mobile", "555-555-5678"]}
{"_id":"10000", "$idx":["Work", "555-555-9012"]}
3 document(s) found.

```

### Troubleshooting Use Cases

Situations where you can use this command are as follows:

- List the contents of an index.
- Resolve encoding errors encountered inserting into an index.

See [Troubleshooting Secondary Indexes](#) on page 1207 for more information on these use cases.

### dbshell insert

#### Description

The `dbshell insert` command adds documents to JSON tables. Specify the ID of the document in one of two ways:

- As the value of the `_id` field in the document
- As the value of the `--id` parameter in the `insert` command

If a document with the specified ID already exists, the command replaces the document with the new one.

## Parameters

| insert Options                | Description                                                                                                                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *, --t, --table<br>(Required) | Table path                                                                                                                                                                        |
| --id                          | ID of the document to insert or replace                                                                                                                                           |
| --v, --value<br>(Required)    | JSON document to insert or replace                                                                                                                                                |
| --c, --where                  | OJAI condition, in JSON format<br>The condition must qualify to perform the insert. See <a href="#">OJAI Query Condition Syntax</a> on page 2882 for a description of the syntax. |

## Syntax

```
insert --table <table path> --value '{"_id": "<row-key", < table field >}'
```

```
insert --table <table path> --id <row-key> --value '{"_id": "<row-key", < table field >}'
```

### Example: Insert with \_id Field

The following examples insert a document into a table using an `_id` field value:

```
insert /data/movies --value '{"_id":"movie0000002",
 "title":"Developers on the Edge",
 "studio":"Command Line Studios"}'
```

```
insert /tables/users --value '{"_id":"user001",
 "first_name":"John",
 "last_name":"Doe"}'
```

### Example: Insert with --id Parameter

The following examples insert a document into a table using the `--id` parameter in the insert command:

```
insert /data/movies --id movie0000003 --value '{"title":"The Golden
Master",
 "studio":"All-Nighter"}'
```

```
insert /tables/users --id user002 --value '{"first_name":"Jane",
 "last_name":"Dane"}'
```

## dbshell jsonoptions

### Description

The `jsonoptions` command sets the JSON output and displays the output appropriately.

## Parameters

### Table

| jsonoptions Options    | Description                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --pretty               | <p>Enables or disables pretty printing mode</p> <p>Value: true false</p> <p>Default: true</p> <p>Pretty print mode displays the content of the documents as an indented hierarchy of field/value pairs. For example, if the value is <code>true</code>, the DATE data type appears as a Map:</p> <pre>"dob" : { "\$dateDay": "2012-10-20" }</pre> |
| --withtags, --withTags | <p>Enables or disables printing with extended JSON data type tags</p> <p>Value: true false</p> <p>Default: true</p> <p>For example, if the value is <code>false</code>, the DATE data type appears as a simple value:</p> <pre>"dob" : "2012-10-20"</pre>                                                                                         |

### Syntax

```
jsonoptions --pretty <true|false>
jsonoptions --withTags <true|false>
```

### Example

```
jsonoptions --pretty true
jsonoptions --withTags false
```

### dbshell list

#### Description

Lists all JSON tables in a folder or that matches a specific file pattern where the table resides.

#### Parameters

### Table

| list Options            | Description                  |
|-------------------------|------------------------------|
| *, --p, --patternOrPath | A path and/or a file pattern |

### Syntax

```
list <path>
```

## Example and Output

```
maprdb root:>list /demo
/demo/user
/demo/checkin
/demo/review
/demo/business
/demo/tip
5 table(s) found.
```

## dbshell replace

### Description

The `dbshell replace` command replaces a document in a JSON table. You can specify a condition with the command.

### Parameters

| replace Options                                                        | Description                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>*</code> , <code>--t</code> , <code>--table</code><br>(Required) | Table path                                                                                                                                                                                                                                                                                     |
| <code>--id</code><br>(Required)                                        | ID of the document to replace<br>If the specified ID does not exist, the command inserts a new document with the values provided in the command.<br> <b>Note:</b> You can specify this parameter only once. |
| <code>--v</code> , <code>--value</code><br>(Required)                  | JSON document to insert or replace                                                                                                                                                                                                                                                             |
| <code>--c</code> , <code>--where</code>                                | OJAI condition, in JSON format<br>The condition must qualify to perform the replace. See <a href="#">OJAI Query Condition Syntax</a> on page 2882 for a description of the syntax.                                                                                                             |

### Syntax

```
replace /tbl --id <id> --v {<document to replace>} [--c <condition>]
```

### Example

```
replace /tables/users --id user002 --value '{"first_name": "Jane",
"last_name": "Doe"}'
```

## dbshell update

### Description

The `dbshell update` command updates JSON documents using OJAI mutations. An OJAI mutation allows you to append, decrement, delete, increment, combine, replace, and update fields in a JSON document.

The following table lists the mutations OJAI supports. See [Using OJAI Mutation Syntax](#) on page 2837 for a detailed description of all operations. Each operation in the table links to examples in this topic.

| Mutation Operation        | Description                                        |
|---------------------------|----------------------------------------------------|
| <a href="#">Append</a>    | Appends values to binary, string, and array fields |
| <a href="#">Decrement</a> | Decrements field values                            |
| <a href="#">Delete</a>    | Deletes fields                                     |
| <a href="#">Increment</a> | Increments field values                            |
| <a href="#">Merge</a>     | Combines nested documents with existing documents  |
| <a href="#">Put</a>       | Replaces field values or adds new fields           |
| <a href="#">Set</a>       | Updates field values or adds new fields            |

### Parameters

| update Options                             | Description                                                                                                                                                                       |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>*, --t, --table</code><br>(Required) | Table path                                                                                                                                                                        |
| <code>--id</code><br>(Required)            | ID of the document to update<br> <b>Note:</b> You can specify this parameter only once.          |
| <code>--m, --mutation</code><br>(Required) | OJAI document mutation in JSON format<br>See <a href="#">Using OJAI Mutation Syntax</a> on page 2837 for a description of the syntax.                                             |
| <code>--c, --where</code>                  | OJAI condition, in JSON format<br>The condition must qualify to perform the update. See <a href="#">OJAI Query Condition Syntax</a> on page 2882 for a description of the syntax. |

### Syntax

```
update <table path> --id <id> --m <mutation> [--c <condition>]
```

 **Note:** If the mutation provided as a part of the `--m` parameter has spaces, then you must enclose it within single quotes.

### Sample JSON Document

The dbshell update examples in this topic use the following sample JSON document:

```
{
 "_id": "id1",
 "a": {
 "b": [{"boolean": false}, {"decimal": 123.456}],
 "c": {
 "d": 10,
 "e": "Hello"
 }
 },
 "m": "MapR wins"
}
```

## Append Operation

This example performs append operations on fields `a.b` and `a.c.e`:

```
update /tbl --id id1 --m {
 "$append": [{ "a.b": { "appd": 1 } }, { "a.c.e": " MapR" }]
}
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "boolean" : false }, { "decimal" : 123.456 }, { "appd" : 1 }],
 "c" : {
 "d" : 10,
 "e" : "Hello MapR"
 }
 },
 "m" : "MapR wins"
}
```

For more details about the `$append` operation, see [OJAI Append Mutations](#) on page 2838.

## Decrement Operation

This example performs a decrement operation:

```
update /tbl --id id1 --m {
 "$decrement": { "a.c.d": 5 }
}
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "boolean" : false }, { "decimal" : 123.456 }],
 "c" : {
 "d" : 5,
 "e" : "Hello"
 }
 },
 "m" : "MapR wins"
}
```

**Note:** To decrement multiple fields, use an array to specify the fields.

For more details about the `$decrement` operation, see [OJAI Decrement Mutations](#) on page 2839.

## Delete Operation

With the following example, the operation deletes multiple field paths in the document in a single command:

```
update /tbl --id id1 --m {
 "$delete": ["a.b[1]", "a.c.e"]
}
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "boolean" : false }],
 "c" : {
 "d" : 10
 }
 },
 "m" : "MapR wins"
}
```

The following example shows that if you need to delete only a single field, do not use the array notation:

```
update /tbl --id id1 --m {
 "$delete": "a.b[1]"
}
```

For more details about the `$delete` operation, see [OJAI Delete Mutations](#) on page 2840.

### Increment Operation

This example performs an increment operation:

```
update /tbl --id id1 --m {
 "$increment": {"a.c.d":5}
}
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "boolean" : false }, { "decimal" : 123.456 }],
 "c" : {
 "d" : 15,
 "e" : "Hello"
 }
 },
 "m" : "MapR wins"
}
```

**Note:** To increment multiple fields, use an array to specify the fields.

For more details about the `$insert` operation, see [OJAI Increment Mutations](#) on page 2840.

### Merge Operation

This example performs a merge operation:

```
update /tbl --id id1 --m {
 "$merge": {"a.c": {"d":11, "y": "yo"}}
}
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "boolean" : false }, { "decimal" : 123.456 }],
 "c" : {
 "d" : 11,
 "e" : "Hello",
 "y" : "yo"
 }
 },
 "m" : "MapR wins"
}
```

**Note:** `$merge` does not support the array format for merging two maps at two different field paths in the document.

For example, the following syntax is incorrect:

```
// WRONG Syntax
update /tbl --id id1 --m {"$merge":["a":{"b":1},{a":{"d":"MapR"}}]}
```

The following syntax is correct:

```
// CORRECT Syntax
update /tbl --id id1 --m {"$merge":{"a":{"b":1,"d":"MapR"}}}
```

It results in the following document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : 1,
 "c" : {
 "d" : 10,
 "e" : "Hello"
 }
 },
 "d" : "MapR"
},
 "m" : "MapR wins"
}
```

To merge multiple field paths that are non-overlapping, use the syntax described at either [Multiple Mutation Operations](#) on page 5512 or [Updates Without Explicit Mutation Operation Names](#) on page 5514.

For more details about the `$merge` operation, see [OJAI Merge Mutations](#) on page 2841.

## Put Operation

This example performs a put operation. Unlike the set operation, the put *replaces* field values. Like the set operation, you do not need an array representation for a single field.

```
update /tbl --id id1 --m {
 "$put":[{"a.b":{"boolean":true},{a.c.d:"eureka"}},{a.x:1}]
}
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : { "boolean" : true },
 "c" : {
 "d" : "eureka",
 "e" : "Hello"
 },
 "x" : 1
 },
 "m" : "MapR wins"
}
```

For more details about the `$set` operation, see [OJAI Put Mutations](#) on page 2842.

### Set Operation

With this example, the command updates the document fields `a.b[0].boolean`, `a.c.d`, and `a.x`. If the field does not exist, the update command creates and sets it. The update fails if the existing field type does not match the new value. If the field exists and is the same type, the value is updated.

```
update /tbl --id id1 --m {
 "$set": [{"a.b[0].boolean":true}, {"a.c.d":11}, {"a.x":1}]
}
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "boolean" : true }, { "decimal" : 123.456 }],
 "c" : {
 "d" : 11,
 "e" : "Hello"
 },
 "x" : 1
 },
 "m" : "MapR wins"
}
```

**Note:** If you need to set only a single field, the command looks like the following:

```
update /tbl --id id1 --m {
 "$set": {"a.b[0].boolean":true}
}
```

For more details about the `$set` operation, see [OJAI Set Mutations](#) on page 2843.

### Multiple Mutation Operations

You can combine more than one mutation operation in a single OJAI mutation by specifying each operation separated by a comma.

The following is an example that combines multiple operations:

```
update /tbl --id id1 --m
' {
 "$set": { "x": [1, 2, 3] },
 "$put": { "a.c.e": { "$binary": "AAAADg==" } },
 "$increment": "a.b[1].decimal",
 "$delete": "a.b[0]",
 "$merge": { "newDoc": { "k": "MapR DBShell rocks!!" } },
 "$append": { "m": "!!!" }
}'
```

The following is the resulting output:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "decimal" : 124.456 }],
 "c" : {
 "d" : 10,
 "e" : { "$binary" : "AAAADg==" }
 }
 },
 "m" : "MapR wins!!!",
 "newDoc" : { "k" : "MapR DBShell rocks!!" },
 "x" : [1, 2, 3]
}
```

The operations behave in the following manner:

- The `$set` operation adds a new array `[1, 2, 3]` with field path `x` into the document.
- The `$put` operation replaces the existing string `"Hello"` with a nested document `{ "$binary": "AAAADg==" }`.
- The `$delete` operation deletes the field path `a.b[0]` from the document.
- The `$merge` operation merges a new nested document `{ "newDoc": { "k": "MapR DBShell rocks!!" } }`.
- The `$append` operates appends the string `"!!!"` to the end of the string `"MapR wins"`.
- The `$increment` and `$delete` operate on different elements of the array `a.b`:
  - The `$increment` operation increments the value `123.456` in the second element of the array `a.b`.
  - The `$delete` operation deletes the field path `a.b[0]`, resulting in a single element array `a.b`.

### Conflicting Operations

When you specify a mutation with field paths that are overlapping, HPE Ezmeral Data Fabric Database detects the conflict, discards the previous conflicting operation, and proceeds with the next operation.

For example, suppose you have the following document:

```
{ "_id": "id1", "a": { "b": { "c": 5 } } }
```

The following mutation has two operations with overlapping fields `a.b`:

```
{ "$delete": "a.b", "$set": { "a.b.d": 10 } }
```

You may have intended for the mutation to first delete `a.b` and then to replace it with `a.b.d` as follows:

```
{ "_id": "id1", "a": { "b": { "d": "10" } } }
```

But the *actual* result is the following:

```
{ "_id": "id1", "a": { "b": { "c": 5, "d": "10" } } }
```

In this case, the set operation on `a.b.d` causes the delete operation on `a.b` to be discarded.

**Note:** In the earlier example in this section, the `$increment` and `$delete` operations are not conflicting because one operates on `a.b[1]`, while the other operates on `a.b[0]`. On the other hand, the following are conflicting operations:

```
{ "$increment": "a.b[1].decimal", "$delete": "a.b" }
```

### Updates Without Explicit Mutation Operation Names

As part of the update command, you can merge a nested document with a document without specifying a mutation operation name. When applying this type of update, the behavior is the same as the merge operation.

For example, suppose you run the following command:

```
update /tbl --id id1 --m {
 "k": "eureka",
 "a": { "c": { "d": 1234 } }
}
```

If the document with key `id1` exists, the update command merges the nested document with the original document. If the document does not exist, the update creates a new document with the input provided.

Application of the command to the sample document results in the following:

```
{
 "_id" : "id1",
 "a" : {
 "b" : [{ "boolean" : false }, { "decimal" : 123.456 }],
 "c" : {
 "d" : 1234,
 "e" : "Hello"
 }
 },
 "k" : "eureka",
 "m" : "MapR wins"
}
```

For the following update command:

```
update /tbl --id id1 --m {
 "k": "eureka",
 "a": { "c": { "d": null } }
}
```

This is the resulting document:

```
{
 "_id" : "id1",
 "a" : {
```

```

 "b" : [{ "boolean" : false }, { "decimal" : 123.456 }],
 "c" : {
 "d" : null,
 "e" : "Hello"
 }
 },
 "k" : "eureka",
 "m" : "MapR wins"
}

```

 **Note:** In this example, field `a.c.d` remains in the document and is set to null.

## Utilities for HPE Ezmeral Data Fabric Database JSON Tables

HPE Ezmeral Data Fabric Database JSON provides utilities to copy, export, and import data, compare table content, and verify the consistency of secondary indexes.

You can use the following utilities with HPE Ezmeral Data Fabric Database JSON tables:

### HPE Ezmeral Data Fabric Database JSON CopyTable

Copies data from one HPE Ezmeral Data Fabric Database JSON table to another HPE Ezmeral Data Fabric Database JSON table.

If the destination table does not exist, `mapr copytable` creates the destination table with the same metadata (column families and access control expressions) as the source table, and then copies data.

If the destination table exists, `mapr copytable` copies data only.

### Required Permissions

The user that runs `mapr copytable` must have the following permissions, which you can grant with access-control expressions:

- The permission `readAce` on the volume where the source table is located, and the permission `writeAce` on the volume where the destination table is or will be located.
- The permission `adminperm` on the source table.
- The permission for column-family and column reads (`readperm`) on the data in the source table that you want to copy.
- When `bulkload = false`, the permission for column writes (`writeperm`) on the destination table.
- When `bulkload = true` (default), the permission to load the destination table with bulk loads (`bulkloadperm`).
- If the destination table does not yet exist: `createrenamefamily` on the source table.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on tables, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

 **Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

## Syntax

```

mapr copytable
-src <source table path>
-dst <destination table path>
[-fromID <start key>]
[-toID <end key>]
[-bulkload <true|false> (default: false)]
[-mapreduce <true|false> (default: true)]
[-cmpmeta <true|false> (default: true)]
[-numthreads <number of threads> (default: 16)]
[-maxsplits <integer> (default: 2000)]

```

## Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src        | The path of the table that you want to copy from.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| dst        | The path of the table that you want to copy to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| fromID     | The value of the <code>_id</code> field in the first document of the range of documents to copy.<br><code>startRow</code> is an alias for this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| toID       | The value of the <code>_id</code> field in the last document of the range of documents to copy.<br><code>stopRow</code> is an alias for this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| bulkload   | A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is not to use bulk loading ( <code>false</code> ). To use bulk load, you must set the <code>-bulkload</code> parameter of the table to <code>true</code> by running the command <code>maprcli table edit -path &lt;path to table&gt; -bulkload true</code> .                                                                                                                                                                                                                |
| mapreduce  | A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program ( <code>true</code> ).<br><br>When this parameter is set to <code>false</code> , a client process uses multiple threads to read rows of the source table and write rows to the destination table.                                                                                                                                                                                                        |
| cmpmeta    | A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata ( <code>true</code> ). Such comparisons are done when the destination table exists before <code>mapr copytable</code> is run and checks that the user ID that runs <code>mapr copytable</code> has the proper permissions on the destination table.<br><br>Set the value of this parameter to <code>false</code> before copying a table that contains a single column family to a table that contains two or more column families. |
| numthreads | When <code>-mapreduce</code> is <code>false</code> , this parameter specifies the number of threads allocated to perform the copying of data. The default is 16. If additional CPU resources are available, you might want to increase the number of threads to achieve better performance.                                                                                                                                                                                                                                                                                     |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxsplits | Sets the maximum number of destination table presplit tablets. Default is 2000. If <code>copytable</code> fails with an Error NO ENtry message during table creation, the operation could not complete within the timeout (10 minutes). Reduce the value of <code>-maxsplits</code> . This functionality requires a patch. See <a href="#">Applying a Patch</a> . |

### Example

The following example copies documents starting from ID `user000001` to ID `user009999`:

```
[user@hostname ~]$ mapr copytable -src /user1/tableA -dst
/mapr/clusterB/vol1/tableB -fromID user000001 -toID user009999
```

### Monitoring `mapr copytable` Operations

Use one of the following methods to monitor the progress of the copying of table data:

- If the copy table operation runs as a MapReduce v2 application, monitor the application using the ResourceManager UI.
- If the copy table operation runs as a client process, go to the Tables view of the destination table in the MapR Control System. Then, on the Region tab, monitor the pace at which the number of rows increases.

### HPE Ezmeral Data Fabric Database JSON DiffTables

Compares the row keys, column families, and field values in two JSON tables. Then, generates two directories that contain sequence files that you can use to merge the rows from the two JSON tables.

Sequence files are binary flat files. For more detail, see [Sequence File](#). To convert a sequence file into a format that you can read, use the `mapr formatresult` utility.

This utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that it contains a superset of the rows defined in both tables at the time at which the utility was run.

This utility generates both of the following output directories in the output directory that you specify:

|                  |                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>opsForDst</b> | A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table. |
| <b>opsForSrc</b> | A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table. |

A user with write permissions on a table can run the `mapr importtable` utility to implement the changes that are specified in the sequence files.

### Required Permissions

The user that runs the `mapr difftables` utility must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- The permission for column reads (`readperm`) on each table.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on tables, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

## Syntax

```
mapr difftables
-src <source table path>
-dst <destination table path>
-outdir <output directory>
[-first_exit Exit when first difference is found.]
[-columns comma-separated list of field paths]
[-mapreduce] <true|false> (default: true)
[-numthreads <numThreads> (default:16, valid only when -mapreduce is false)]
[-cmpmeta <true|false> (default: true)]
```

## Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src        | The path of the first table to include in the comparison.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| dst        | The path of the second table to include in the comparison.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| first_exit | By default, the utility compares all the table cells in the specified tables. Use this parameter if you want to exit after the first difference is identified between the tables. The parameter takes no value.                                                                                                                                                                                                                                                                                                                                                                                               |
| outdir     | The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| columns    | By default, the utility compares all fields in JSON tables. If you do not want to compare all fields, you can specify specific fields to include in the comparison. For example, suppose that want to compare a source table in table replication with a replica of that table. When you set up replication, you chose to replicate the default column family and two additional column families: <code>cf1</code> and <code>cf2</code> . For the <code>-columns</code> parameter, you would specify the value <code>" ,cf1,cf2"</code> , where the default column family is represented by the empty string. |
| mapreduce  | A Boolean value that specifies whether or not to use a MapReduce program to perform the comparison. The default, preferred method is to use a MapReduce program (true).<br><br>When this parameter is set to false, a client process uses multiple threads to perform the comparison.                                                                                                                                                                                                                                                                                                                         |
| numthreads | When <code>-mapreduce</code> is false, this parameter specifies the number of threads allocated to perform the comparison. The default is 16. If additional CPU resources are available, you might want to increase the number of thread to achieve better performance.                                                                                                                                                                                                                                                                                                                                       |

| Parameter | Description                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| cmpmeta   | A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (true). |

### Example

The following example shows a comparison of two JSON tables

```
[user@hostname ~]$ mapr diffTables -src /source_JSON_table -dst /
destination_JSON_table -outdir output/comparison1 -columns
"dateRange.endYear","contributors.date"
Header: hostName: maprdemo, Time Zone: Pacific Standard Time, processName:
null, processId: null
2015-10-01 14:46:22,537 INFO com.mapr.db.mapreduce.tools.DiffTables
parseArgs main: Comparing dateRange.endYear,contributors.date column
families from /source_JSON_table to /destination_JSON_table.
DiffTablesMeta completed. Metadata of the two tables is same.

tables '/source_JSON_table', and '/destination_JSON_table' didn't match
Number of rows processed in '/source_JSON_table' : 100
Number of rows processed in '/destination_JSON_table' : 100
Mismatch row count in '/source_JSON_table' : 1
Mismatch row count in '/destination_JSON_table' : 1
Rows with mismatch are stored in output/comparison1
```

### HPE Ezmeral Data Fabric Database JSON DiffTablesWithCrc

This utility uses a cyclic redundancy check to detect differences between sets of rows in the specified HPE Ezmeral Data Fabric Database JSON tables. Then, for each set of non-identical rows, it performs a detailed comparison. Finally, it generates one or more directories of sequence files. You can use these files either to merge the rows from two HPE Ezmeral Data Fabric Database JSON tables.

Sequence files are binary flat files. You can learn more about them [here](#). To convert a sequence file into a format that you can read, use the [HPE Ezmeral Data Fabric Database JSON FormatResult](#) on page 5521 utility.

This utility requires less network bandwidth than the `mapr diffTables` utility because it performs a detailed table comparison only on the sets of rows where the CRC algorithm detected a difference. Therefore, consider using this utility when the tables you compare are very similar and you are concerned about the data transfer rate.

This utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that each table can contain a superset of the rows in both tables at the time at which the utility was run.

This utility generates the following output directories:

- **opsForDst.** A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table.
- **opsForSrc.** A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table.

Run the `mapr importtable` command to implement the puts and deletes specified in the sequence files.

A user with write permissions on a table can run the `mapr importtable` utility to implement the changes that are specified in the sequence files.

### Requirements

- When the cluster runs YARN, it must use zero configuration failover for the ResourceManager.
- The user that runs the `mapr difftableswithcrc` utility must have the following permissions:
  - The permission `readAce` on the volumes where the tables are located.
  - The permission for column reads (`readperm`) on each table.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on tables, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

### Syntax

```
mapr difftableswithcrc
-src <source table path>
-dst <destination table path>
-outdir <output directory>
[-first_exit] Exit when first difference is found.
[-columns <comma separated list of field paths>]
[-exclude_embedded_families <true|false>] (default: false)
 Don't include the other column families with path embedded in specified
columns
[-cmpmeta <true|false> (default: true)]
```

### Parameters

| Parameter | Description                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src       | The path of the first table to include in the comparison.                                                                                                                          |
| dst       | The path of the second table to include in the comparison.                                                                                                                         |
| outdir    | The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails. |

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| first_exit | By default, the utility compares all the table cells in the specified tables. Use this parameter if you want to exit after the first difference is identified between the tables. The parameter takes no value.                                                                                                                                                                                                                                                                                                                                                                                                 |
| columns    | By default, the utility compares all fields in JSON tables. If you do not want to compare all fields, you can specify specific fields to include in the comparison. For example, suppose that you want to compare a source table in table replication with a replica of that table. When you set up replication, you chose to replicate the default column family and two additional column families: <code>cf1</code> and <code>cf2</code> . For the <code>-columns</code> parameter, you would specify the value <code> ,cf1,cf2</code> , where the default column family is represented by the empty string. |
| cmpmeta    | A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (true).                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### HPE Ezmeral Data Fabric Database JSON FormatResult

Parses a sequence file generated by the `diffTables` utility for JSON tables and converts the results into a format that makes the results easier to understand.

#### Required Permissions

The user that runs the `FormatResult` utility must have the `readAce` and `writeAce` permissions on the volumes where the input and output paths are located.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

#### Syntax

```
mapr formatresult
-indir <input file path>
-outdir <output file path>
[-mapreduce <true|false> (default: false)]
```

#### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| indir     | The path to a file or directory of files that contains the output of the <code>mapr diffTables</code> utility.                                                                                                                                                                                                            |
| outdir    | The path to a file or a directory for the output. If the file or directory already exists, the utility fails. When a single sequence file is provided as input, the utility generates a single output file. When a directory of sequence files is provided as input, the utility generates a directory with output files. |
| mapreduce | A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (true).                                                                                                                                            |

## Example

This example shows the results of the following actions that followed a comparison by difftables of two JSON tables:

1. Formatting the sequence file for the source JSON table.
2. Formatting the sequence file for the destination JSON table.
3. Viewing the content of the first sequence file.
4. Viewing the content of the second sequence file.

This is the command that was used for `maprdb difftables`:

```
mapr difftables -src /src_table -dst /dest_table -outdir
output/diffs -columns dateRange.endYear
```

Here is the command that was used for `mapr formatresult` and the resulting output:

```
[user@hostname ~]$ mapr formatresult -indir output/diffs/
OpsForSrcTable -outdir output/outputForSrcTable5
Header: hostName: maprdemo, Time Zone: Pacific Standard Time, processName:
null, processId: null

### HPE Ezmeral Data Fabric Database JSON ExportTable and ImportTable

Use these utilities together to export data from JSON tables into binary sequence files, and then import the data from the binary sequence files into other JSON tables. You can also use the `mapr importtable` utility to import changes that are specified in sequence files output by the `mapr difftables` utility.

- [Syntax of `mapr exporttable`](#)
- [Parameters of `mapr exporttable`](#)
- [Syntax of `mapr importtable`](#)
- [Parameters of `mapr importtable`](#)
- [Example of using `mapr exporttable` and `mapr importtable` together](#)

### Required Permissions

- The `readAce` permission on the volume where the source table for `mapr exporttable` is located.
- The `writeAce` permission on the volume in which to save the output from `mapr exporttable`.
- The `readAce` permission on the volume where the files output by `mapr exporttable` is located.
- The `writeAce` permission on the volume in which the destination table is located.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run these utilities unless that user is given the relevant permission or permissions with access-control expressions.

### Syntax of `mapr exporttable`

```
mapr exporttable
(option)
-src Name of table
-dst Directory path
[-columns Fields to include]
[-mapreduce : <true|false>, default is true]
```

### Parameters of `mapr exporttable`

| Parameter | Description                                                      |
|-----------|------------------------------------------------------------------|
| src       | The path of the JSON table to export from.                       |
| dst       | The directory within the MapR filesystem to export the files to. |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| columns   | <p>A comma-delimited list of fields to include in the exported files.</p> <p><b>Example</b></p> <pre>a,b,c</pre> <p>Do not use quotation marks and do not include spaces after commas.</p>                                                                                                                                                                            |
| mapreduce | <p>The cluster must have <a href="#">YARN</a> installed and configured for this option to work.</p> <p>A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true).</p> <p>When this parameter is set to false, a client process uses multiple threads.</p> |

### Syntax of `mapr importtable`

```
mapr importtable
(option)
-src Input binary file or directory path
-dst Destination table
[-bulkload <true|false>, default is false]
[-mapreduce : <true|false>, default is true]
```

### Parameters of `mapr importtable`

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src       | <p>The path of the binary file or files to import.</p> <p><b>Examples</b></p> <pre>-src /temp/part0 -src /temp/*</pre>                                                                                                                                                                                                                                                |
| dst       | The JSON table to import the data into.                                                                                                                                                                                                                                                                                                                               |
| bulkload  | <p>A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is not to use bulk loading (false). To use bulk load, you must set the <code>-bulkload</code> parameter of the table to <code>true</code> by running the command <code>maprcli table edit -path &lt;path to table&gt; -bulkload true</code>.</p>               |
| mapreduce | <p>The cluster must have <a href="#">YARN</a> installed and configured for this option to work.</p> <p>A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true).</p> <p>When this parameter is set to false, a client process uses multiple threads.</p> |

**Example of using `mapr exporttable` and `mapr importtable` together**

```
[user@hostname ~]$ mapr exporttable -columns contributors,creditLine -src /
collection/artworks -dst /tempExport
Header: hostName: hostname, Time Zone: Pacific Standard Time, processName:

**HPE Ezmeral Data Fabric Database JSON ImportJSON**

Imports one or more JSON documents into a HPE Ezmeral Data Fabric Database JSON table. The JSON documents must be flat text files.

**Required Permissions**

- The `readAce` permission on the volume where the JSON documents to import are located.
- The `writeAce` permission on the volume in which the destination table is located.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

**Syntax**

```
mapr importJSON
[-idfield <Name of ID field in JSON Data>]
[-bulkload <true|false>, default is false]
[-mapreduce : <true|false>, default is true]
-src <text file or directory>
-dst <JSON table>
```

**Parameters**

-

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| idfield   | <p>The name of the field that contains the value to use for each document's <code>_id</code> field.</p> <p>An <code>_id</code> field is inserted into each document that is imported into a table, if the document does not already contain one.</p> <p>Documents that do not already contain an <code>_id</code> field must contain a field with a value that can be used for the inserted <code>_id</code> field.</p> <p>For example, each document might have a <code>product_ID</code> field with a value that would be suitable for the <code>_id</code> field.</p> <p>Use quotation marks around the name.</p> |
| bulkload  | <p>A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is not to use bulk loading (<code>false</code>). To use bulk load, you must set the <code>-bulkload</code> parameter of the table to <code>true</code> by running the command <code>maprcli table edit -path &lt;path to table&gt; -bulkload true</code>.</p> <p>This parameter cannot be set to <code>true</code> when the <code>-mapreduce</code> parameter is set to <code>false</code>.</p>                                                                                                               |
| mapreduce | <p>A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (<code>true</code>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                   |
| src       | <p>The path of a JSON document in text format or a directory of such documents.</p> <p>If you specify a directory and that directory contains only the JSON files to import, use an asterisk at the end of the path, as in this example: <code>/user/data/*</code></p> <p>If you specify a directory and that directory contains both the JSON files to import and other files, use a more specific wildcard, such as <code>*.json</code>.</p> <p>The path must be in the MapR filesystem. To move files there from the Linux filesystem, use the command <code>hadoop fs -copyFromLocal</code>.</p>                 |
| dst       | <p>The path of the destination HPE Ezmeral Data Fabric Database JSON table.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### Example

Suppose you have the following three JSON documents in the `/tmp/users` directory in your MapR filesystem:

```
$ hadoop fs -cat /tmp/users/bcumings.json
{"_id":"bcummings","first_name":"Bettie","last_name":"Cummings"}

$ hadoop fs -cat /tmp/users/gjones.json
{"_id":"gjones","first_name":"Gilberto","last_name":"Jones"}

$ hadoop fs -cat /tmp/users/jdoe.json
{"_id":"jdoe","first_name":"John","last_name":"Doe"}
```

The following command imports the three documents into the JSON table in the path `/apps/users`:

```
$ mapr importJSON -idField _id -src /tmp/users/* -dst /apps/users
```

You can run `mapr dbshell` to see the imported documents:

```
maprdb mapr:> find /apps/users
{"_id":"bcummings","first_name":"Bettie","last_name":"Cummings"}
{"_id":"gjones","first_name":"Gilberto","last_name":"Jones"}
{"_id":"jdoe","first_name":"John","last_name":"Doe"}
3 document(s) found.
```

### HPE Ezmeral Data Fabric Database JSON verifyindex

Describes how to use the HPE Ezmeral Data Fabric Database JSON `verifyindex` command to verify that the data in a secondary index is consistent with its JSON table.

### Syntax

```
mapr verifyindex
 -path < table path >
 -index < index name >
 -first_exit < true | false >
 -numthreads < thread number >
```

### Parameters

| Parameter  | Description                                                                                 |
|------------|---------------------------------------------------------------------------------------------|
| path       | (Required) Path to where the table exists.                                                  |
| index      | (Required) Name of the secondary index on the table.                                        |
| first_exit | (Optional) Exit when the first difference is found. Options: true or false. Default: false. |
| numthreads | (Optional) Number of parallel threads to use for the verification. Default: 16              |

### Example

The following example creates a table, creates a secondary index on the table, inserts some documents, and then runs the `verifyindex` command to verify that there is data consistency between the JSON table and the secondary index. See [Troubleshooting Secondary Indexes](#) on page 1207 for an example where `verifyindex` detects data inconsistency.

```
// Create a table using dbshell add
mapr dbshell

maprdb root:> create /t1
Table /t1 created.

// Create an index using maprcli table index add
maprcli table index add -path /t1 -index il -indexedfields a -json
{
 "timestamp":1499788406380,
 "timeofday":"2017-07-11 08:53:26.380 GMT-0700",
 "status":"OK",
 "total":0,
 "data":[]
```

```

}

// Insert documents into the table using dbshell insert
mapr dbshell

maprdb root:> insert /t1 --v {"a":1,"b":2} --id 1
Document with id: "1" inserted.

maprdb root:> insert /t1 --v {"a":"mapr","b":3} --id 2
Document with id: "2" inserted.

maprdb root:> insert /t1 --v {"a":{"$numberLong":3},"b":4} --id 4
Document with id: "4" inserted.

// Run verifyindex to verify indexed data
mapr verifyindex -path /t1 -index il

Number of rows in table but not in index: 0
Number of rows in index but not in table: 0
Mismatch row count: 0

```

### Troubleshooting Use Cases

Situations where you can use this command are as follows:

- Examine details on updates that have not yet propagated from a JSON table to one of its indexes.
- Detect if there are documents that are missing from an index.
- Detect other data consistency issues between an index and its parent JSON table.

See [Troubleshooting Secondary Indexes](#) on page 1207 for more information on these use cases.

### HPE Ezmeral Data Fabric Database HBase Shell (Binary Tables)

You can manage HPE Ezmeral Data Fabric Database tables using HBase shell commands and additional HBase shell commands included in the HPE Ezmeral Data Fabric distribution of Hadoop.

The HBase shell command is used on binary tables only. To run this command, execute the following:

```
hbase shell
```

 **Note:** Before running the shell, ensure that your user ID has both the `readAce` and `writeAce` permissions on the volume. For information about these permissions, see [Managing Whole Volume ACEs](#).

When you specify a table in HBase shell, use the following syntax:

- For a table on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path as the table name: `"/volume1/test"`
- For a table on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path as the table name: `"/mapr/sanfrancisco/volume1/customer"`

 **Note:** You can access a table on a remote cluster when the remote cluster has an entry in the [mapr-clusters.conf](#) file on the node where the HBase shell is running.

The following table lists the supported HBase shell commands that you can use to manage HPE Ezmeral Data Fabric Database tables:

| Command     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| alter       | <p>Performs the following actions on HPE Ezmeral Data Fabric Database tables:</p> <ul style="list-style-type: none"> <li>• Adds a new table or column family</li> <li>• Modifies the following table-level attributes: <ul style="list-style-type: none"> <li>• BULKLOAD - A Boolean value that specifies whether to perform a full bulk load of the table. The default is false. For more information, see <a href="#">Bulk Loading and HPE Ezmeral Data Fabric Database Tables</a>.</li> <li>• MAX_FILESIZE</li> <li>• AUTOSPLIT - A Boolean value that specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the <code>regionsize</code> parameter. The default value is true. If you set the value to false, you can manually split tables into regions by using the <code>maprcli table region split</code> command.</li> </ul> </li> <li>• Modifies the following attributes of a column family: <ul style="list-style-type: none"> <li>• TTL</li> <li>• VERSIONS (max or min)</li> <li>• COMPRESSION</li> <li>• IN_MEMORY</li> </ul> </li> </ul> <p>Aside from the attributes listed above, no other attributes apply to HPE Ezmeral Data Fabric Database tables. Unlike HBase, you do not need to disable a table before altering a table.</p> |
| alter_async | On HPE Ezmeral Data Fabric Database tables, this has the same behavior as the alter command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| count       | Counts the number of rows in a specified table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| create      | Creates a table in the specified path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| delete      | Deletes a value in a specified table, row, and column. Optionally, you can also specify the timestamp associated with the value that you want to delete.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| deleteall   | Delete all values in a row based on the table name and row. Optionally, you can also specify the timestamp associated with the values that you want to delete.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| describe    | Describes a specified table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| disable     | Marks a specified table as disabled. This state is recorded only in the client process (HBase shell) memory and does not actually disable any operations on a HPE Ezmeral Data Fabric Database table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Command      | Description                                                                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| disable_all  | Marks tables as disabled if they have names matching the specified regular expression. This state is recorded only in the client process (HBase shell) memory and does not actually disable any operations on the HPE Ezmeral Data Fabric Database tables. |
| drop         | Drops a specified table that is marked as disabled.                                                                                                                                                                                                        |
| drop_all     | Drops all tables that are marked as disabled.                                                                                                                                                                                                              |
| enable       | Marks a specified table as enabled. This state is recorded only in the client process (HBase shell) memory.                                                                                                                                                |
| enable_all   | Marks tables as enabled if they have a table name that matches the specified regular expression. This state is recorded only in the client process (HBase shell) memory.                                                                                   |
| exists       | Returns boolean value true if the specified table exists.                                                                                                                                                                                                  |
| exit         | Exits the HBase shell.                                                                                                                                                                                                                                     |
| get          | Gets the contents of a row or cell.                                                                                                                                                                                                                        |
| get_counter  | Returns the value of a counter at a specified table, row, and column.                                                                                                                                                                                      |
| incr         | Increments a value at a specified table, row, and column.                                                                                                                                                                                                  |
| is_disabled  | Returns a value that indicates if a specified table is disabled. You can perform operations on HPE Ezmeral Data Fabric Database tables that are disabled.                                                                                                  |
| is_enabled   | Returns a value that indicates if a specified table is enabled. You can perform operations on HPE Ezmeral Data Fabric Database tables even if they are not enabled.                                                                                        |
| list         | For HBase 1.1 or above, if the <code>mapr.hbase.default.db</code> property is set to <code>maprdb</code> , this command returns the HPE Ezmeral Data Fabric Database tables under the user's home directory.                                               |
| list_perm    | Lists all permissions set by Access Control Expressions for a specified table. This HBase shell command only operates on HPE Ezmeral Data Fabric Database tables. For more information, see <a href="#">list_perm</a> .                                    |
| put          | Puts a value at a specified table, row, and column. Optionally, you can also specify the timestamp for that value.                                                                                                                                         |
| scan         | Scans a specified table. Optionally, you can also specify a dictionary of scanner specifications.                                                                                                                                                          |
| set_perm     | Sets permissions with Access Control Expressions on a specified table, column family, or column qualifier. This Hbase shell command only operates on HPE Ezmeral Data Fabric Database tables. For more information, see <a href="#">set_perm</a> .         |
| show_filters | Shows all the filters supported by the Hbase or HPE Ezmeral Data Fabric Database tables. Provide the link to 4.1 supported filters doc                                                                                                                     |
| truncate     | Disables, drops, and recreates a specified table.                                                                                                                                                                                                          |
| version      | Returns the HBase client version.                                                                                                                                                                                                                          |
| whoami       | Returns the current user.                                                                                                                                                                                                                                  |

HPE Ezmeral Data Fabric Database does not support the following HBase shell commands:

- add\_peer
- alter\_status
- assign
- balance\_switch
- balancer
- close\_region
- compact
- disable\_peer
- enable\_peer
- flush
- grant
- hlog\_roll
- list\_peer
- major\_compact
- move
- remove\_peer
- start\_replication
- stop\_replication
- status
- split
- revoke
- unassign
- user\_permission
- zk\_dump

For more information about the HBase shell commands, see the [Apache HBase documentation](#).

### **list\_perm**

Lists all permissions set by Access Control Expressions for a specified HPE Ezmeral Data Fabric Database table

### **Syntax**

```
list_perm "<table path>"
```

## Example

```
hbase(main):006:0> list_perm "/table/"
Scope Permission Access Control Expression
defaultappendperm u:jon
createrenamefamilyperm u:jon
deletefamilyperm u:jon
bulkloadperm u:jon
defaultreadperm u:jon
defaultwriteperm u:jon
packperm u:jon
replperm u:jon
defaultmemoryperm u:jon
adminaccessperm u:jon
splitmergeperm u:jon
defaultversionperm u:jon
defaultcompressionperm u:jonr
13 row(s) in 0.0070 seconds
```

## set\_perm

Set permissions with access control expressions on a MapR Database table, column family, or column qualifier.

Set permissions with [ACE](#) on a HPE Ezmeral Data Fabric Database table, column family, or column qualifier.

## Syntax

To set the permission on a table:

```
set_perm "<table path>", "<permission>", "<ACE expression>"
```

To set the permission on a column family or column qualifier:

```
set_perm "<table path>", {COLUMN => "column family[:qualifier]", PERM =>
 "<permission>", EXPR => "<ACE expression>"}
```

## Examples

Assigns user jon and user mapr04 the defaultreadperm permission on table /table:

```
hbase(main):004:0> set_perm "/table/","defaultreadperm","u:jon|u:mapr04"
```

Assigns user jon and user mapr05 the compressionperm permission on the cf1 column family in table /table:

```
hbase(main):005:0> set_perm "/table/",{COLUMN => "cf1",PERM =>
 "compressionperm", EXPR =>"u:jon|u:mapr05"}
```

Assigns user jon and user mapr05 the writeperm permission on the col1 column qualifier in cf1 column family in table /table:

```
hbase(main):009:0> set_perm "/table/",{COLUMN => "cf1:col1",PERM =>
 "writeperm", EXPR =>"u:jon|u:mapr05"}
```

## Utilities for HPE Ezmeral Data Fabric Database Binary Tables

HPE Ezmeral Data Fabric Database provides utilities to copy and compare data in HPE Ezmeral Data Fabric Database binary tables.

You can use the following utilities with HPE Ezmeral Data Fabric Database binary tables:

### HPE Ezmeral Data Fabric Database Binary CopyTable

Copies data from one HPE Ezmeral Data Fabric Database binary table to another HPE Ezmeral Data Fabric Database binary table.

The HPE Ezmeral Data Fabric Database `CopyTable` utility is different from Apache HBase's [CopyTable](#) utility. This utility has the following capability:

- If the destination table does not exist, `CopyTable` creates the target table with the same metadata (column families and access control expressions) as the source table, and then copies data.
- If the destination table exists, `CopyTable` copies data only.
- If you manually set up replication to a HPE Ezmeral Data Fabric Database table, `CopyTable` can be used to perform an initial load of source data to the replica before table replication begins.

**Note:** When copying data to HPE Ezmeral Data Fabric Database tables, it is recommended that you use the HPE Ezmeral Data Fabric Database version of `CopyTable`.

### Required Permissions

The user that runs the `CopyTable` utility must have the following permissions:

- The permission `readAce` on the volume where the source table is located, and the permission `writeAce` on the volume where the destination table is or will be located.
- The permission `adminperm` on the source table.
- The permission for column-family and column reads (`readperm`) on the data in the source table that you want to copy.
- When `bulkload = false`, the permission for column writes (`writeperm`) on the destination table.
- When `bulkload = true` (default), the permission to load the destination table with bulk loads (`bulkloadperm`).
- If the destination table does not yet exist: `createrenamefamily` on the source table.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

If `CopyTable` is run between tables on different clusters, the user that runs the command must have the required permissions on each cluster.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on tables, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

### Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable
 -src <source table path> -dst <destination table path>
 [-columns cf1[:col1],...] [-maxversions <max number of versions to
copy>]
 [-starttime <time>]
 [-endtime <time>]
 [-mapreduce <true|false> (default: true)]
```

```
[-bulkload <true|false> (default: true)]
[-numthreads <numThreads> (default:16, valid only when -mapreduce is
false)]
```

## Parameters

| Parameters  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src         | <p>The path to the source table that you want to replicate.</p> <ul style="list-style-type: none"> <li>For a path on the local cluster, start the path at the volume mount point. For example, for a table named <code>testsrc</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testsrc</code></li> <li>For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customersrc</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customersrc</code></li> </ul> |
| dst         | <p>The path to the replica.</p> <ul style="list-style-type: none"> <li>For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>testdst</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testdst</code></li> <li>For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code></li> </ul>                               |
| columns     | <p>By default, all columns in the source table are copied. If you do not want to copy all columns in the table, you can specify columns to copy. Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier).</p> <p>For example, use the following syntax to copy only the purchases column family and the stars column in the reviews column family: <code>-columns purchases, reviews:stars</code></p>                                                                                                                                                                                                               |
| maxversions | <p>By default, all versions from the source table are copied. If you do not want to copy all versions, use this parameter to specify the number of versions to copy.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| starttime   | <p>By default, all table values regardless of their associated timestamp are copied. You can specify a timestamp to indicate the table cell version at which to start the copy. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps lower than the specified timestamp will not be copied to the destination.</p>                                                                                                                                                                                                                                                                               |

| Parameters | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| endtime    | By default, all table values regardless of their associated timestamp are copied. You can specify a timestamp to indicate the table cell version at which to end the copy. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps greater than or equal to the specified timestamp will not be copied to the destination.                         |
| mapreduce  | A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program ( <code>true</code> ).<br><br>When this parameter is set to <code>false</code> , a client process uses multiple threads to read rows of the source table and write rows to the destination table.                                                       |
| bulkload   | A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is to use bulk loading ( <code>true</code> ). When you use bulk loading, the utility automatically unsets the bulk load mode on the table to restore normal client operations at the end of the table copy operation. For more information, see <a href="#">Bulk Loading and HPE Ezmeral Data Fabric Database Tables</a> . |
| numthreads | When <code>-mapreduce</code> is <code>false</code> , this parameter specifies the number of threads allocated to perform the copying of data. The default is 16. If additional CPU resources are available, you might want to increase the number of threads to achieve better performance.                                                                                                                                    |

### Monitoring the CopyTable Operation

Use one of the following methods to monitor the progress of the copying of table data:

- If the copy table operation runs as a MapReduce v2 application, monitor the application using the ResourceManager UI.
- If the copy table operation runs as a client process, go to the Tables view of the destination table in the MapR Control System. Then, on the Region tab, monitor the pace at which the number of rows increases.

### Example

Copies table data with timestamp greater than 1423226300000 (Fri, 06 Feb 2015 12:38:20 GMT) from one HPE Ezmeral Data Fabric Database table to another HPE Ezmeral Data Fabric Database table:

```
[user@hostname ~]$
hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable -src /t1 -dst /
t1_copy7 -starttime 1423226300000
```

### HPE Ezmeral Data Fabric Database Binary DiffTables

Compares the row key, column family, timestamp, and value of each table cell in each specified HPE Ezmeral Data Fabric Database table. Then, it generates one or two directories with [sequence files](#) that you can use to either make a HPE Ezmeral Data Fabric Database table identical to its master or merge the rows from two HPE Ezmeral Data Fabric Database tables.

Sequence files are binary flat files. To convert the sequence file into a format that is easier to understand, use the [FormatResults](#) utility.

By default, the DiffTables utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that it contains a superset of the rows defined in both tables at the time at which the utility was run.

When you specify a master table, the DiffTables utility generates one of the following output directories:

- **opsForDst.** A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table.
- **opsForSrc.** A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table.

A user with write permissions on a table can run the `hbase org.apache.hadoop.hbase.mapreduce.Import` command to implement the puts and deletes specified in the sequence files.

### Required Permissions

The user that runs the DiffTables utility must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- The permission for column reads (`readperm`) on each table.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on tables, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

### Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.DiffTables
 -src <source table path>
 -dst <destination table path>
 -outdir <output directory>
 [-master <src|dst>] The master table to use for the diff.
 [-first_exit] Exit when first difference is found.
 [-columns <comma separated list of family[:column]>]
 [-starttime <start diff at timestamp>]
 [-endtime <end diff at timestamp>]
 [-maxversions] <max number of versions to diff>
 [-mapreduce] <true|false> (default: true)
 [-numthreads <numThreads> (default:16, valid only when -mapreduce is
 false)]
 [-cmpmeta <true|false> (default: true)]
```

## Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code></li> </ul> |
| master     | <p>The table that is considered to be the master table. The values are <code>src</code> and <code>dst</code>. By default, both the source table and the destination tables are considered to be a master.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| first_exit | <p>By default, the utility compares all the table cells in the specified tables. Use this parameter if you want to exit after the first difference is identified between the tables. The parameter takes no value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| outdir     | <p>The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| columns    | <p>By default, the utility compares all columns. If you do not want to compare all columns in the table, you can specify specific columns to include in the comparison. Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to include the column family <code>purchases</code> and the column <code>stars</code> in the <code>reviews</code> column family: <code>-columns purchases, reviews:stars</code></p>                                                                                                                                       |
| starttime  | <p>By default, the utility compares all table values regardless of their associated timestamp. You can specify a timestamp to indicate the table cell version at which to start the comparison. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps lower than the specified timestamp will not be included in the comparison.</p>                                                                                                                                                                                                                                           |

| Parameter   | Description                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| endtime     | By default, the utility compares all table values regardless of their associated timestamp. Values with timestamps greater than or equal to the specified timestamp will not be included in the comparison.                                                 |
| maxversions | By default, all versions from the master table are included in the comparison. If you do not want to compare all versions, use this parameter to specify the number of recent versions to include in the comparison.                                        |
| mapreduce   | A Boolean value that specifies whether or not to use a MapReduce program to perform the comparison. The default, preferred method is to use a MapReduce program (true).<br><br>When this parameter is set to false, a client process uses multiple threads. |
| numthreads  | When -mapreduce is false, this parameter specifies the number of threads allocated to perform the comparison. The default is 16. If additional CPU resources are available, you might want to increase the number of thread to achieve better performance.  |
| cmpmeta     | A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (true).                                                                                                        |

### Examples

The following example compares two HPE Ezmeral Data Fabric Database tables:

```
[user@hostname ~]$ hbase com.mapr.fs.hbase.tools.mapreduce.DiffTables -src /
customerTableA -dst /customerTableB -outdir /customerTableABCompare
2015-03-04 18:04:52,059 INFO [main] Configuration.deprecation:
hadoop.native.lib is deprecated. Instead, use io.native.lib.available
DiffTablesMeta completed. Metadata of the two tables is same.
...
Mapreduce job completed. The tables mismatch.
NUM_ROWS_MISMATCH_IN_SRC:32; NUM_ROWS_MISMATCH_IN_DST:30. Please check diff
in /customerTableABCompare
```

### HPE Ezmeral Data Fabric Database Binary DiffTablesWithCrc

This utility uses a cyclic redundancy check to detect differences between sets of rows in the specified HPE Ezmeral Data Fabric Database binary tables. Then, for each set of non-identical rows, it performs a detailed comparison. Finally, it generates one or more directories of sequence files. You can use these files either to make a HPE Ezmeral Data Fabric Database binary table identical to its master or merge the rows from two HPE Ezmeral Data Fabric Database binary tables.

Sequence files are binary flat files. You can learn more about them [here](#). To convert a sequence file into a format that you can read, use the [HPE Ezmeral Data Fabric Database Binary FormatResult](#) on page 5541 utility.

This utility requires less network bandwidth than the `DiffTables` utility because it performs a detailed table comparison only on the sets of rows where the CRC algorithm detected a difference. Therefore, consider using this utility when the tables you compare are very similar and you are concerned about the data transfer rate.

### Requirements

- When the cluster runs YARN, it must also use zero configuration failover for the ResourceManager.

By default, the utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that it can contain a superset of the rows defined in both tables at the time at which the utility was run.

When you specify a master table, the `mapr difftableswithcrc` utility generates one of the following output directories:

- **opsForDst.** A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table.
- **opsForSrc.** A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table.

A user with write permissions on a table can run the `hbase org.apache.hadoop.hbase.mapreduce.Import` command to implement the puts and deletes specified in the sequence files.

### Required Permissions

The user that runs the `mapr difftableswithcrc` utility must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- The permission for column reads (`readperm`) on each table.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on tables, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

### Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.DiffTablesWithCrc
-src <source table path>
-dst <destination table path>
-outdir <output directory>
[-master src|dst] The master table to use for the diff.
[-first_exit] Exit when first difference is found.
[-cf <comma separated list of column families>]
[-starttime <start diff at timestamp>]
[-endtime <end diff at timestamp>]
[-maxVersions <max number of versions to copy>]
[-cmpmeta <true|false> (default: true)]
```

## Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src        | <p>The path to the source table.</p> <ul style="list-style-type: none"> <li>For a path on the local cluster, start the path at the volume mount point. For example, for a table named <code>testsrc</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testsrc</code></li> <li>For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named <code>customersrc</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customersrc</code></li> </ul>        |
| dst        | <p>The path to the destination table.</p> <ul style="list-style-type: none"> <li>For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code></li> </ul> |
| master     | <p>The table that is considered to be the master table. The values are <code>src</code> (the source table) and <code>dst</code> (the destination table). By default, both the source table and the destination table are considered to be the master.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |
| first_exit | <p>By default, the utility compares all the table cells in the specified tables. Set this parameter if you want to exit after the first difference is identified between the tables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| outdir     | <p>The path to a directory for the sequence files. The utility will create the specified directory. If the specified directory already exists, the command will fail.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| cf         | <p>By default, the utility compares all columns from the master table. If you do not want to compare all columns in the table, you can specify specific columns to include in the comparison. Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to include the column family <code>purchases</code> and the column <code>stars</code> in the <code>reviews</code> column family: <code>-columns purchases, reviews:stars</code></p>                                                                                                                 |
| starttime  | <p>By default, the utility compares all table values regardless of their associated timestamp. You can specify a timestamp to indicate the table cell version at which to start the comparison. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps lower than the specified timestamp will not be included in the comparison.</p>                                                                                                                                                                                                                                           |

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| endtime     | By default, the utility compares all table values regardless of their associated timestamp. You can specify a timestamp to indicate the table cell version at which to end the comparison. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps greater than or equal to the specified timestamp will not be included in the comparison. |
| maxVersions | By default, the utility compares all versions from the master table. If you do not want to diff all versions, use this parameter to specify the number of recent versions to include in the comparison.                                                                                                                                                                                                                 |
| cmpmeta     | A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata ( <code>true</code> ).                                                                                                                                                                                                                                                     |

### Example

Compares two HPE Ezmeral Data Fabric Database tables:

```
[user@hostname ~]$
hbase com.mapr.fs.hbase.tools.mapreduce.DiffTablesWithCrc -src /
customerTableA -dst /customerTableB -outdir /customerTableCompare
2015-03-04 17:52:40,912 INFO [main] Configuration.deprecation:
hadoop.native.lib is deprecated. Instead, use io.native.lib.available
DiffTablesMeta completed. Metadata of the two tables is same.
....
Mapreduce job completed. The tables mismatch.
NUM_ROWS_MISMATCH_IN_SRC:32; NUM_ROWS_MISMATCH_IN_DST:30. Please check diff
in /customerTableCompare
```

### HPE Ezmeral Data Fabric Database Binary FormatResult

Parses a sequence file generated by the `DiffTables` utility or the `DiffTablesWithCrc` utility and converts the results into a format that makes the results easier to understand.

#### Required Permissions

The user that runs the `FormatResult` utility must have the `readAce` and `writeAce` permissions on the volumes where the input and output paths are located.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

#### Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.FormatResult
-input <input file path>
-output <output file path>
[-mapreduce <true|false> (default: false)]
```

## Parameters

| Parameters | Description                                                                                                                                                                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| input      | The path to a file or directory of files that contains the output of either the DiffTables utility or the DiffTablesWithCrc utility.                                                                                                                                                                                      |
| output     | The path to a file or a directory for the output. If the file or directory already exists, the utility fails. When a single sequence file is provided as input, the utility generates a single output file. When a directory of sequence files is provided as input, the utility generates a directory with output files. |
| mapreduce  | A Boolean value that specifies whether or not to use a MapReduce program to perform the FormatResult operation. The default is not to use a MapReduce program (false).                                                                                                                                                    |

### Example

Formats a sequence file:

```
[user@hostname ~]$ hbase
com.mapr.fs.hbase.tools.mapreduce.FormatResult -input /dif1/tf4/opsForDst/opsForDst-m-00001 -output /dif1/tf4/opsForDst_single/nomr -mapreduce false
2015-03-06 18:58:56,210 INFO [main] Configuration.deprecation: fs.default.name is deprecated. Instead, use fs.defaultFS
2015-03-06 18:58:57,492 INFO [main] mapreduce.FormatResult: Translated sequence file maprfs:///dif1/tf4/opsForDst/opsForDst-m-00001 to text file /dif1/tf4/opsForDst_single/nomr
2015-03-06 18:58:57,527 INFO [main] mapreduce.FormatResult: Total 1 text files created.
```

## HPE Ezmeral Data Fabric Event Streams Utilities

You can use the following utilities to with HPE Ezmeral Data Fabric Event Streams streams:

### **mapr copystream**

This utility copies data from one Data Fabric Event Stream to another Data Fabric Event Stream. You can use it, for example, if you want to set up replication manually from one stream to another.

If the destination stream does not exist, `mapr copystream` creates the destination stream with the same metadata as the source stream, and then copies data.

If the destination stream exists, `mapr copystream` copies data only.

### Required Permissions

To use this utility, you must have the following permissions:

- The permission `readAce` on the volume where the source stream is located, and the permission `writeAce` on the volume where the destination stream is located.
- On the source stream: either `consumeperm` or `copyperm`.
- On the destination stream: either `copyperm` or all three of the following permissions: `produceperm`, `consumeperm`, `topicperm`

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on streams, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Event Streams does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

## Syntax

```
mapr copystream
-src <srcStream>
-dst <dstStream>
[-mapreduce true/false default:false]
[-numthreads <nthreads> default:16]
```

## Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src        | The path and name of the stream to copy messages from.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| dst        | The path and name of the stream to copy messages to.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| mapreduce  | <p>A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (true).</p> <p>When this parameter is set to false, a client process uses multiple threads to read from the source stream and write to the destination stream.</p> <p>The MapReduce program runs as a MapReduce version 2 application based on the MapReduce mode that is configured on this node.</p> |
| numthreads | When <code>-mapreduce</code> is false, this parameter specifies the number of threads allocated to perform the copying of data. The default is 16. If additional CPU resources are available, you might want to increase the number of threads to achieve better performance.                                                                                                                                                                                                    |

### `mapr diffstreams`

This utility compares the message IDs, metadata, and data in two Data Fabric Event Streams. Then, generates two directories that contain sequence files that you can use to merge the rows from the two Data Fabric Event Streams.

Sequence files are binary flat files. You can learn more about them [here](#). To convert a sequence file into a format that you can read, use the [HPE Ezmeral Data Fabric Database JSON FormatResult](#) on page 5521 utility.

This utility considers both the source stream and the destination stream to be a master stream. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each stream so that it contains a superset of the rows defined in both tables at the time at which the utility was run.

This utility generates both of the following output directories in the output directory that you specify:

#### `opsForDst`

A directory containing sequence files that correspond to each put and delete required to make the destination stream identical to the source stream.

**opsForSrc**

A directory containing sequence files that correspond to each put and delete required to make the source stream identical to the destination stream.

**Required Permissions**

To use this utility, you must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- On the source stream: either `consumeperm` or `copyperm`.
- On the destination stream: either `consumeperm` or `copyperm`.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on streams, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Event Streams does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

**Syntax**

```
mapr diffstreams
-src <srcStream>
-dst <dstStream>
-outdir <output directory>
[-first_exit] Exit when first difference is found
[-mapreduce true/false default:false]
[-numthreads <nthreads> default:16]
```

**Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src        | The path of the first stream to include in the comparison.                                                                                                                                                                                                                                                                                                                                      |
| dst        | The path of the second stream to include in the comparison.                                                                                                                                                                                                                                                                                                                                     |
| outdir     | The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.                                                                                                                                                                                                              |
| first_exit | By default, the utility compares all the data in the specified streams. Use this parameter if you want to exit after the first difference is identified between the streams. The parameter takes no value.                                                                                                                                                                                      |
| mapreduce  | A Boolean value that specifies whether or not to use a MapReduce program to perform the comparison. The default, preferred method is to use a MapReduce program (true).<br><br>When this parameter is set to false, a client process uses multiple threads.<br><br>The MapReduce program runs as a MapReduce version 2 application based on the MapReduce mode that is configured on this node. |

| Parameter  | Description                                                                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| numthreads | When <code>-mapreduce</code> is false, this parameter specifies the number of threads allocated to perform the comparison. The default is 16. If additional CPU resources are available, you might want to increase the number of thread to achieve better performance. |

### `mapr diffstreamswithcrc`

This utility uses a cyclic redundancy check to detect differences between sets of messages in the specified Data Fabric Event Streams. Then, for each set of non-identical messages, it performs a detailed comparison. Finally, it generates one or more directories of sequence files.

You can use these files either to make a Data Fabric Event Stream identical to its master or merge the messages from two Data Fabric Event Streams.

Sequence files are binary flat files. You can learn more about them [here](#). To convert a sequence file into a format that you can read, use the [HPE Ezmeral Data Fabric Database JSON FormatResult](#) on page 5521 utility.

This utility requires less network bandwidth than the `mapr diffstreams` utility because it performs a detailed table comparison only on the sets of messages where the CRC algorithm detected a difference. Therefore, consider using this utility when the streams you compare are very similar and you are concerned about the data transfer rate.

This utility considers both the source stream and the destination stream to be a master stream. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each stream so that each stream can contain a superset of the messages in both streams at the time at which the utility was run.

These are the directories that the utility generates:

#### `opsForDst`

A directory containing sequence files that correspond to each put and delete required to make the destination stream identical to the source stream.

#### `opsForSrc`

A directory containing sequence files that correspond to each put and delete required to make the source stream identical to the destination stream.

## Requirements

- When the cluster runs YARN, it must also use zero configuration failover for the ResourceManager.
- To use this utility, you must have the following permissions:
  - The permission `readAce` on the volumes where the tables are located.
  - On the source stream: either `consumeperm` or `copyperm`.
  - On the destination stream: either `consumeperm` or `copyperm`.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on streams, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Event Streams does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Run the `mapr importstream` command to implement the puts and deletes specified in the sequence files.

### Syntax

```
mapr diffstreamswithcrc
-src <srcStream>
-dst <dstStream>
-outdir <output directory>
[-first_exit] Exit when first difference is found
```

### Parameters

| Parameter  | Description                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src        | The path of the first stream to include in the comparison.                                                                                                                                                 |
| dst        | The path of the second stream to include in the comparison.                                                                                                                                                |
| outdir     | The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.                         |
| first_exit | By default, the utility compares all the data in the specified streams. Use this parameter if you want to exit after the first difference is identified between the streams. The parameter takes no value. |

### `mapr exportstream` and `mapr importstream`

Use these utilities together to export data from Data Fabric Event Streams into binary sequence files, and then import the data from the binary sequence files into other Data Fabric Event Streams. You can also use the `mapr importstream` utility to import changes that are specified in sequence files output by the `mapr diffstreams` utility.

- [Syntax of `mapr exportstream`](#)
- [Parameters of `mapr exportstream`](#)
- [Syntax of `mapr importstream`](#)
- [Parameters of `mapr importstream`](#)

### Required Permissions

To use the `mapr exportstream` utility, you must have the following permissions:

- The `readAce` permission on the volume where the source stream for `mapr exportstream` is located.
- The `writeAce` permission on the volume in which to save the output from `mapr exportstream`.
- On the source stream: either `consumeperm` or `copyperm`
- On the destination directory: write permission

To use the `mapr importstream` utility, you must have the following permissions:

- The `readAce` permission on the volume where the files output by `mapr exportstream` is located.
- The `writeAce` permission on the volume in which the destination stream is located.

- On the source directory: read permission on the directory and all of the files within it
- On the destination stream: either `copyperm` or all three of the following permissions: `produceperm`, `consumeperm`, `topicperm`

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on streams, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Event Streams does not allow the `mapr` user to run these utilities unless that user is given the relevant permission or permissions with access-control expressions.

### Syntax of `mapr exportstream`

```
mapr exportstream
-src <srcStream>
-dst <dstDir>
[-mapreduce true/false default:false]
```

### Parameters of `mapr exportstream`

| Description | Parameter                                                                                                                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src         | The stream to export data from.                                                                                                                                                                                                                            |
| dst         | The directory within the Data Fabric filesystem to export the files to. This directory must already exist before you run the utility.                                                                                                                      |
| mapreduce   | A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true).<br><br>When this parameter is set to false, a client process uses multiple threads. |

### Syntax of `mapr importstream`

```
mapr importstream
-src Input binary file or directory path
-dst Destination stream
[-mapreduce true/false default:false]
```

### Parameters of `mapr importstream`

| Description | Parameter                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------|
| src         | The path of the binary file or files to import.<br><br><b>Examples</b><br><br>-src /temp/part0<br>-src /temp/* |
| dst         | The stream to import data into.                                                                                |

| Description | Parameter                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mapreduce   | <p>A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true).</p> <p>When this parameter is set to false, a client process uses multiple threads.</p> |

### `mapr perfconsumer`

This utility runs a consumer reading messages from topics in a Data Fabric Event Stream. Use this utility to run consumers when you want to estimate the performance of consumers for your Data Fabric Event Streams applications, given your network configuration.

This utility works in conjunction with the `mapr perfproducer` utility. When starting this utility, you can specify how many topics to read from, how many partitions to read from in each topic, and how many messages to read.

The `mapr perfconsumer` utility uses the default values for all of the configuration parameters that apply to consumers. For a list of these parameters, see [HPE Ezmeral Data Fabric Event Streams Configuration Parameters](#).

The utility uses the default values for all of the configuration parameters that apply to consumers.

Each consumer runs as a single thread. You can run multiple instances of the utility at the same time. However, because consumers can be CPU-intensive, it is recommended to run at most 4 or 5 on a single cluster node.

When you run multiple instances of this utility, you can use the `-group` parameter to create consumer groups.

Monitor the performance of the running instances of the `mapr perfconsumer` utility by following the instructions that are given in [Monitoring Consumers](#).

### Prerequisites for running this utility

- Ensure that there is a Data Fabric Event Stream that one or more instances of `mapr perfproducer` have already published messages to or are actively publishing messages to.
- Ensure that the user ID that runs the `mapr perfconsumer` utility has the `consumeperm` permission on the stream.
- Ensure that the user ID that runs the `mapr perfconsumer` utility has the `readAce` and `writeAce` permissions on the volume where the stream is located.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on streams, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Event Streams does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

### Syntax

```
mapr perfconsumer
-path <stream-full-name>
[-ntopics <num topics> (default: 2)]
[-npart <numpartitions per topic> (default: 4)
```

```
[-nmsgs <num messages per topicfeed> (default: 100000)]
[-group <consumer group id> (default: null)
[-topicsubscription <true/false> (default: false)]
```

## Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path              | The path to the stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ntopics           | The number of topics for the consumer to subscribe to.<br>The default is 2.<br>If the number that you specify is greater than the number of topics that are in the stream, the utility hangs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| npart             | The number of partitions to read from in each topic that is subscribed.<br>The default is 4.<br>If the number that you specify is greater than the number of partitions that are in each topic, the utility hangs.<br>If you specify a group ID with the <code>-group</code> parameter, the consumer's committed cursors are saved.<br>If you do not specify a group ID, then the consumer's committed cursors are not saved.<br>If you use the <code>-group</code> parameter to specify a group ID and you set the <code>-topicsubscription</code> parameter to <code>true</code> : <ul style="list-style-type: none"> <li>If the consumer fails, it's partitions can be redistributed among other consumer in the same group. If the consumer is the only consumer within a group, restarting the consumer with the same group ID causes the consumer to begin reading from the offsets of the saved committed cursors.</li> <li>If the consumer fails and is then restarted, it starts at the oldest message in each partition.</li> </ul> |
| nmsgs             | The number of messages to read from each partition.<br>The default is 100,000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| group             | The identifier of a consumer group. When two or more consumers belong to a consumer group, they must read from the same number of topics. HPE Ezmeral Data Fabric Event Streams distributes the partitions for those topics among the consumers in the group.<br>The default is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| topicsubscription | A value of <code>true</code> subscribes the consumer to topics. A value of <code>false</code> subscribes the consumer to topic partitions.<br>The default is <code>false</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### `mapr perfproducer`

This utility runs a producer, generating messages and publishing them to a Data Fabric Event Stream. Use this utility to run producers when you want to estimate the performance of producers for your Data Fabric Event Streams applications, given your network configuration.

This utility starts a producer and generates data for the producer to publish in messages to a Data Fabric Event Stream. When starting the utility, you can specify how many topics the producer publishes to, how many partitions to create for each topic, and how many messages to publish to each partition. You can also specify the method for distributing messages among the partitions in each topic.

For example, suppose you run the utility by issuing this command:

```
mapr perfproducer -path /myVolume/myDirectory/stream_a -ntopics
40 -npart -5
-nmsgs 100000 -rr true
```

The producer automatically creates 40 topics in the stream, creating each topic as it writes the first message to that topic. Each topic is created with 5 partitions. The producer writes 100,000 messages to each partition for a total of 20,000,000 messages. After publishing all of the messages, the utility terminates.

The `mapr perfproducer` utility uses the default values for all of the configuration parameters that apply to producers. For a list of these parameters, see [HPE Ezmeral Data Fabric Event Streams Configuration Parameters](#).

Each producer runs as a single thread. You can run multiple instances of the utility at the same time. However, because producers can be CPU-intensive, it is recommended to run at most 4 or 5 on a single cluster node.

When multiple instances of the `mapr perfproducer` utility publish to a single stream, the separate instances share topics. For example, if `-ntopics` is set to 40 for each instance that publishes to a single stream, together those instances create no more than 40 topics in the stream and they share those topics.

It is recommended that all producers that publish to a single cluster publish to the same number of topics and partitions within those topics. Therefore, use the same values for `-ntopics` and `-npart` for each instance of the `mapr perfproducer` utility that shares a stream with other instances.

Monitor the performance of the running instances of the `mapr perfproducer` utility by issuing the `maprcli` command `stream topic info` at intervals, as described in [Monitoring Producers](#). The command `stream topic info` shows statistics for single topics. Because all of the topics that `mapr perfproducer` creates have the same number of partitions, and because `mapr perfproducer` writes the same number of messages to each partition, you can assume that the statistics that the command `stream topic info` displays for any one topic are close to the statistics for any other topic. The naming convention that `mapr perfproducer` uses when creating topics is simply `topicn`, which produces the names `topic0`, `topic1`, and so on. You can run the command `stream topic info` with any one of these names as the value of the `-topic` parameter.

To simulate consumers to estimate the performance of HPE Ezmeral Data Fabric Event Streams in your network configuration, run one or more instances of the `mapr perfconsumer` utility against the stream.

### Prerequisites for running this utility

- Create a Data Fabric Event Stream in a Data Fabric cluster for the `mapr perfproducer` utility to publish messages to. See [stream create](#) on page 1999.

If you plan to replicate the stream for the purposes of the performance estimate, create the replica stream. Then, start replication from the first stream to the replica stream. For instructions on setting up replication between streams, see [Managing Stream Replication](#) on page 1245.

- Ensure that the user ID that runs the `mapr perfproducer` utility has the `readAce` and `writeAce` permissions on the volume where the stream is located.
- Ensure that the user ID that runs the `mapr perfproducer` utility has the `produceperm` and `topicperm` permissions on the stream.

For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

For information about how to set permissions on streams, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Event Streams does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

## Syntax

```
mapr perfproducer
-path <stream-full-name>
[-ntopics <num topics> (default: 2)]
[-npart <numpartitions per topic> (default: 4)]
[-nmsgs <num messages per topicfeed> (default: 100000)]
[-msgsz <msg value size> (default: 200)]
[-rr <round robin true/false> (default: false)]
[-hashkey <true/false> (default: false)]
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path      | The path to the stream.                                                                                                                                                                                                                                                                                                                                                                                                    |
| ntopics   | The number of topics for the producer to publish to in the stream.<br>The default is 2.                                                                                                                                                                                                                                                                                                                                    |
| npart     | The number of partitions to create for each topic.<br>The default is 4.                                                                                                                                                                                                                                                                                                                                                    |
| nmsgs     | The number of messages to publish to each partition.<br>The default is 100,000.                                                                                                                                                                                                                                                                                                                                            |
| msgz      | The size of each message in bytes.<br>The default is 200 bytes.                                                                                                                                                                                                                                                                                                                                                            |
| rr        | Specifies to publish messages to partitions within a topic in round-robin fashion. See <a href="#">How Partitions are Chosen for Messages</a> for detail about this method of distributing messages among topic partitions.<br><b>Note:</b> This parameter is incompatible with the <code>-hashkey</code> parameter. You must set one or the other to true, but not both.<br>The default is <code>false</code> .           |
| hashkey   | Specifies to distribute messages among topic partitions according to the hash of each message key. See <a href="#">How Partitions are Chosen for Messages</a> for detail about this method of distributing messages among topic partitions.<br><b>Note:</b> This parameter is incompatible with the <code>-rr</code> parameter. You must set one or the other to true, but not both.<br>The default is <code>true</code> . |

**mapr streamanalyzer**

This light-weight utility, which is a sample application for the `Streams` Java class for analytics on Data Fabric Event Streams, lets you count the messages in a stream or a subset of the topics in a stream. The utility also lets you print either whole retrieved messages or a subset of the fields in each message.

You can download the source code for this utility here: [StreamAnalyzer.java](#)

For information about the `Streams` Java class and building applications that use it, see [HPE Ezmeral Data Fabric Event Streams Java API Library](#) on page 3033. See [Logical Schema of Messages](#) on page 598 for information about how messages are structured.

Ensure that the user ID that runs the utility has the `readAce` permission on the volume where the stream is located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

**Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Event Streams does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

**Syntax**

```
mapr streamanalyzer -path <stream-full-name>
[-topics <comma separated topic names>]
[-regex <regular expression representing topic names>]
[-countMessages <true/false> (default: true)]
[-printMessages <true/false> (default: false)]
[-projectFields <comma separated field names> (default: all fields)]
```

**Parameters**

| Parameter                  | Description                                                                                                                                                                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>path</code>          | The path and name of the stream.                                                                                                                                                                                                                                                 |
| <code>topics</code>        | A comma-separated list of the names of topics to retrieve. If you do not specify this parameter or the <code>-regex</code> parameter, all of the topics in the stream are retrieved.<br>Do not use this parameter if you use the <code>-regex</code> parameter.                  |
| <code>regex</code>         | A regular expression that represents the names of the topics to retrieve. If you do not specify this parameter or the <code>-topics</code> parameter, all of the topics in the stream are retrieved.<br>Do not use this parameter if you use the <code>-topics</code> parameter. |
| <code>countMessages</code> | Prints the number of retrieved messages to the standard output.                                                                                                                                                                                                                  |
| <code>printMessages</code> | Prints the contents of retrieved messages to the standard output.                                                                                                                                                                                                                |

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| projectFields | <p>If the <code>-printMessages</code> parameter is set to <code>true</code>, this parameter causes only the specified fields to be printed to the standard output for each message. In the list of field names, separate the names with commas. Default: all fields.</p> <p>Valid field names: key, value, topic, offset, partition, and producer.</p> <p>If the <code>-printMessages</code> parameter is set to <code>false</code>, this parameter has no effect.</p> |

## YARN Commands

This section describes the YARN commands.

### Commands

All YARN commands are invoked by the `/usr/bin/yarn` script.

```
Usage: yarn [--config confdir] [COMMAND] [COMMAND_OPTIONS]
```

| COMMAND_OPTION                | Description                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------|
| <code>--config confdir</code> | Overrides the default Configuration directory. Default is <code>\${HADOOP_HOME}/conf</code> . |
| COMMAND                       | Commands                                                                                      |
| COMMAND_OPTIONS               | Command options                                                                               |

The following `yarn` commands may be run on the HPE Ezmeral Data Fabric distribution of Apache Hadoop:

| Command                   | Description                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------|
| <code>application</code>  | Lists applications, or prints the status or kills the specified application.            |
| <code>classpath</code>    | Prints the class path needed to get the Hadoop jar and the required libraries           |
| <code>debugcontrol</code> | Saves additional DEBUG logs for scheduling to a separate file without restarting the RM |
| <code>daemonlog</code>    | Gets and sets the log level for each daemon                                             |
| <code>jar</code>          | Runs jar file                                                                           |
| <code>logs</code>         | Dumps container logs                                                                    |
| <code>node</code>         | Prints node report(s)                                                                   |
| <code>queue</code>        | Prints queue information                                                                |
| <code>rmadmin</code>      | Performs administrative tasks for Resource Manager                                      |
| <code>version</code>      | Print the version                                                                       |

The following `yarn` commands are not supported on the HPE Ezmeral Data Fabric distribution of Apache Hadoop:

- yarn applicationattempt
- yarn cluster
- yarn container
- yarn nodemanager
- yarn proxyserver
- yarn resourcemanager
- yarn sharedcachemanager
- yarn scmadmin
- yarn timelineserver

You can use the `maprccli node services` command or the Control System to start the services. For more information, see [Managing Services](#) on page 904.

### yarn application

The `yarn application` lists applications, or prints the status or kills the specified application.

### Syntax

```
yarn application
 [-list [<-appStates States>] [<-appTypes Types>]]
 [-status ApplicationId]
 [-kill ApplicationId]
```

### Parameters

The following commands parameters are supported for `yarn application`:

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-list [&lt;-appStates States&gt;] [&lt;-appTypes Types&gt;]</code> | Lists applications. Optionally, you can filter the applications based on type or state. <ul style="list-style-type: none"> <li>• Use <code>-appTypes</code> to filter applications based on a comma-separated list of application types.</li> <li>• Use <code>-appStates</code> to filter applications based on a comma-separated list of the following valid application states: ALL, NEW, NEW_SAVING, SUBMITTED, ACCEPTED, RUNNING, FINISHED, FAILED, KILLED</li> </ul> |
| <code>-status ApplicationId</code>                                       | Prints the status of the application.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-kill ApplicationId</code>                                         | Kills the application.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### yarn classpath

The `yarn classpath` command prints the class path needed to access the Hadoop jar and the required libraries.

## Syntax

```
yarn classpath
```

## Output

```
$ yarn classpath
/opt/mapr/hadoop/hadoop-<version>/etc/hadoop:/opt/mapr/hadoop/
hadoop-<version>/etc/hadoop:/opt/mapr/hadoop/hadoop-<version>/etc/
hadoop:/opt/mapr/hadoop/hadoop-<version>/share/hadoop/common/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/common/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/hdfs:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/hdfs/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/hdfs/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/mapreduce/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/mapreduce/*:
/contrib/capacity-scheduler/*.jar:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/lib/*
```

## yarn daemonlog

Gets or sets the log level for each daemon.

## Syntax

```
yarn daemonlog
```

```
[-getlevel <host:port> <name>] | [-setlevel <host:port> <name> <level>]
```

## Parameters

| Parameter                            | Description                                                                                                                                                                                                          |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -getlevel <host:port> <name>         | Prints the log level of the daemon running at <host:port>. This command internally connects to <a href="http://&lt;host:port&gt;/logLevel?log=&lt;name&gt;">http://&lt;host:port&gt;/logLevel?log=&lt;name&gt;</a> . |
| -setlevel <host:port> <name> <level> | Sets the log level of the daemon running at <host:port>. This command internally connects to <a href="http://&lt;host:port&gt;/logLevel?log=&lt;name&gt;">http://&lt;host:port&gt;/logLevel?log=&lt;name&gt;</a> .   |

## yarn debugcontrol

used to save additional DEBUG logs for scheduling in YARN to a separate file without restarting the RM.

The logs are saved in `/opt/mapr/Hadoop/Hadoop<version>/logs/yarn-mapr-scheduling-debug.log`

## Syntax

```
yarn debugcontrol
```

```
[-addapp <application_name>] | [-addqueue <queue_name>] | [-removeapp
<application_name>] | [-removequeue <queue_name>] | [-getapps] |
[-getqueues]
```

**Parameters**

| Parameter                     | Description                                             |
|-------------------------------|---------------------------------------------------------|
| -addapp <application_name>    | enables additional scheduling DEBUG on the application  |
| -addqueue <queue_name>        | enables additional scheduling DEBUG on the queue        |
| -removeapp <application_name> | disable addition scheduling DEBUG on the application    |
| -removequeue <queue_name>     | disable addition scheduling DEBUG on the queue          |
| -getapps                      | lists the applications with additional scheduling DEBUG |
| -getqueues                    | lists the queues with additional scheduling DEBUG       |

**yarn jar**

Runs a jar file that contains YARN code.

**Syntax**

```
yarn jar <jar> [<mainClass>] [<arguments>]
```

**Parameters**

The following commands parameters are supported for `yarn jar`:

| Parameter   | Description                                         |
|-------------|-----------------------------------------------------|
| <jar>       | The JAR file.                                       |
| <mainClass> | Sets the applications entry point.                  |
| <arguments> | Arguments to the program specified in the JAR file. |

**yarn logs**

Dumps the YARN container logs.

**Syntax**

```
yarn logs -applicationId <application ID> [OPTIONS]
```

general options are:

```
-appOwner <Application Owner> AppOwner (assumed to be current user if
 not specified)
-containerId <Container ID> ContainerId (must be specified if node
 address is specified)
-help Displays help for all commands.
-nodeAddress <Node Address> NodeAddress in the format nodename:port
 (must be specified if container id is
 specified)
```

**Parameters**

| Parameter                     | Description                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------|
| -applicationId                | Specifies an application ID.                                                                   |
| -appOwner <Application Owner> | Specifies the application owner. Defaults to the current user if this option is not specified. |

| Parameter                   | Description                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------|
| -containerId <Container ID> | Specifies the container ID. Required when -nodeAddress is specified.                                        |
| -nodeAddress <Node Address> | Specifies the node address in the following format: nodename:port. Required when -containerId is specified. |

**yarn node**

Prints node report(s)

**Syntax**

```
yarn node
 [-list [-states <States>] | [-all]]
 [-status NodeId]
```

**Parameters**

| Parameter                          | Description                                                                                                                                                                                                                                                                        |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -list [-states <states>]   [-all]] | Lists all running nodes. Optionally, filter nodes based on state or choose to list all the nodes. <ul style="list-style-type: none"> <li>Use -states &lt;states&gt; to filter nodes based on a comma-separate list of node states.</li> <li>Use -all to list all nodes.</li> </ul> |
| -status NodeId                     | Prints the status report of the node.                                                                                                                                                                                                                                              |

**yarn queue**

Prints queue information

**Syntax**

```
yarn queue -status <queue name>
```

**Parameters**

The following command parameter is supported for `yarn queue`:

| Parameter | Description     |
|-----------|-----------------|
| status    | The queue name. |

**yarn radmin**

Runs the ResourceManager admin client.

**Syntax**

```
yarn radmin
 [-refreshQueues]
 [-refreshNodes]
 [-refreshUserToGroupsMapping]
 [-refreshSuperUserGroupsConfiguration]
```

```

[-refreshAdminAcls]
[-refreshServiceAcl]
[-getGroups <username>]
[-help <cmd>]
[-transitionToActive <serviceId>]
[-transitionToStandby <serviceId>]
[-getServiceState <serviceId>]
[-checkHealth <serviceId>]

```

## Parameters

| Parameter                            | Description                                                                                                                                                                                                                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -refreshQueues                       | Reloads the queues' acls, states, and scheduler specific properties. The ResourceManager reloads the mapred-queues configuration file.                                                                                                                                            |
| -refreshNodes                        | Refreshes the host information at the ResourceManager.                                                                                                                                                                                                                            |
| -refreshUserToGroupsMappings         | Refreshes user-to-groups mappings.                                                                                                                                                                                                                                                |
| -refreshSuperUserGroupsConfiguration | Refreshes superuser proxy groups mappings.                                                                                                                                                                                                                                        |
| -refreshAdminAcls                    | Refreshes acls for administration of ResourceManager.                                                                                                                                                                                                                             |
| -refreshServiceAcl                   | Reloads the service-level authorization policy file. The ResourceManager reloads the authorization policy file.                                                                                                                                                                   |
| -getGroups <username>                | Gets the groups that the user belongs to.                                                                                                                                                                                                                                         |
| -help <cmd>                          | Displays help for the given parameter or all parameters if no parameter is specified.                                                                                                                                                                                             |
| -transitionToActive <serviceId>      | Transitions the service into the Active state. You can use this parameter when the ResourceManager is configured to failover manually.                                                                                                                                            |
| -transitionToStandby <serviceId>     | Transitions the service into Standby state. You can use this parameter when the ResourceManager is configured to failover manually.                                                                                                                                               |
| -getServiceState <serviceId>         | Returns the service state. You can use this parameter when the ResourceManager is configured to failover manually or automatically but not with the zero configuration failover option.                                                                                           |
| -checkHealth <serviceId>             | Requests a health check for the service. If the health check fails, the RAdmin tool exits with a non-zero exit code. You can use this parameter when the ResourceManager is configured to failover manually or automatically but not with the zero configuration failover option. |

### yarn version

Prints the YARN version.

### Syntax

```
yarn version
```

### Output

```

$ yarn version
Hadoop 2.7.6.100-eep-800
Subversion git@github.com:mapr/private-hadoop-common -r

```

```
80dc89ae5df3a2cd01089f192c5d8a886e4788c9
Compiled by root on 2021-10-08T11:26Z
Compiled with protoc 3.11.1
From source with checksum 124ac1b54c81145154c71d2be2a66fc
This command was run using /opt/mapr/hadoop/hadoop-2.7.6/share/hadoop/
common/hadoop-common-2.7.6.100-eep-800.jar
```

## Source Code for HPE Ezmeral Data Fabric Software

HPE releases source code to the open-source community for enhancements that HPE has made to the Apache Hadoop project and other ecosystem components.

HPE regularly releases updates to Apache Hadoop ecosystem projects as the projects are released by Apache, after HPE can verify that the changes do not impact product stability. Releases of ecosystem components are independent of the release cycle for the core data-fabric software, so that new updates can be released quickly and efficiently.

Source code developed by HPE can be found on GitHub at <http://github.com/mapr> as of March 2013, coincident with version 2.1.2 of the data-fabric distribution. HPE may also release source code for other data-fabric projects at [github.com/mapr](http://github.com/mapr). For each release that HPE includes in its distribution, HPE branches and tags the release on GitHub using the underlying project release number appended by `-mapr`.

### Component Repositories on GitHub

The following repositories are available on GitHub for components that HPE has enhanced, patched, or created.

- [oozie](#)
- [hcatalog](#)
- [pig](#)
- [hive](#)
- [mahout](#)
- [hbase](#)
- [flume](#)
- [whirr](#)
- [opentsdb](#)

**Note:** Select the [highest MEP version supported by the HPE Ezmeral Data Fabric version](#) that you are using.

- [sqoop](#)
- [scribe](#)

### Finding Source Changes Prior to February 2013

GitHub is the single, central location for tracking changes that HPE applies to components in releases of the data-fabric distribution. Prior to February 2013, HPE included a list of patches in each component directory, as shown below. This information is no longer stored in the installation directory for recent releases, and instead is available at GitHub.

**Example: Location of Information about Patches to HBase Prior to February 2012**

```

$ ls /opt/mapr/hbase/hbase-0.92.1/
bin hbase-0.92.1.jar LICENSE.txt pom.xml
CHANGES.txt hbase-0.92.1-tests.jar logs README.txt
conf hbase-webapps mapr-hbase-patches security
conf.new lib NOTICE.txt src

$ ls /opt/mapr/hbase/hbase-0.92.1/mapr-hbase-patches/
0000-hbase-with-mapr.patch 0006-hbase-6285-fix.patch
0001-hbase-wait-for-fs+set-chunksize.patch 0007-hbase-6375-fix.patch
0002-hbase-source-env-vars.patch 0008-hbase-6455-fix.patch
0003-hbase-6158-fix.patch 0009-bug-7745-fix.patch
0004-hbase-6018-fix.patch Readme.txt
0005-hbase-6236-fix.patch

```

**Hadoop Commands**

This section describes the Hadoop commands.

All Hadoop commands are invoked by the `bin/hadoop` script.

**Overview**

This section contains the following:

**Syntax Summary**

The following syntax summary applies to all commands.

```

hadoop [--config confdir] [COMMAND] [GENERIC_OPTIONS] [COMMAND_OPTIONS]
hadoop2 [--config confdir] [COMMAND] [GENERIC_OPTIONS] [COMMAND_OPTIONS]

```

Hadoop has an option parsing framework that employs parsing generic options as well as running classes.

| COMMAND_OPTION                | Description                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-mode</code>            | For both the <code>hadoop</code> and <code>hadoop2</code> commands, setting this option is no longer valid. Both commands default to <code>yarn</code> , the only valid mode for the current MapR version. |
| <code>--config confdir</code> | Overwrites the default Configuration directory. Default is <code>\${HADOOP_HOME}/conf</code> .                                                                                                             |
| COMMAND                       | Various commands with their options are described in the following sections.                                                                                                                               |
| GENERIC_OPTIONS               | The common set of options supported by multiple commands.                                                                                                                                                  |
| COMMAND_OPTIONS               | Various command options are described in the following sections.                                                                                                                                           |

**Note:** Running the `hadoop` script without any arguments prints the help description for all commands.

**Supported Commands for Hadoop 2.x**

MapR supports the following `hadoop` commands for Hadoop 2.x:

| Command                                                          | Description                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>archive -archiveName NAME &lt;src&gt;* &lt;dest&gt;</code> | Creates a Hadoop archive, a file that contains other files. A Hadoop archive always has a <code>.har</code> extension.                                                                                                                                                                                                                    |
| <code>CLASSNAME</code>                                           | The <code>hadoop</code> script can be used to invoke any class.<br><code>hadoop CLASSNAME</code> runs the class named <code>CLASSNAME</code> .                                                                                                                                                                                            |
| <code>classpath</code>                                           | Prints the class path needed to access the Hadoop JAR and the required libraries.                                                                                                                                                                                                                                                         |
| <code>conf</code>                                                | The <code>hadoop conf</code> command prints the configuration information for the current node.                                                                                                                                                                                                                                           |
| <code>daemonlog</code>                                           | The <code>hadoop daemonlog</code> command may be used to get or set the log level of Hadoop daemons.                                                                                                                                                                                                                                      |
| <code>distcp &lt;source&gt; &lt;destination&gt;</code>           | The <code>hadoop distcp</code> command is a tool for large inter- and intra-cluster copying. It uses MapReduce to effect its distribution, error handling and recovery, and reporting. It expands a list of files and directories into input to map tasks, each of which will copy a partition of the files specified in the source list. |
| <code>fs</code>                                                  | The <code>hadoop fs</code> command runs a generic filesystem user client that interacts with the MapR filesystem.                                                                                                                                                                                                                         |
| <code>jar &lt;jar&gt;</code>                                     | The <code>hadoop jar</code> command runs a JAR file. Users can bundle their MapReduce code in a JAR file and execute it using this command.                                                                                                                                                                                               |
| <code>mfs</code>                                                 | The <code>hadoop mfs</code> command performs operations on directories in the cluster. The main purposes of <code>hadoop mfs</code> are to display directory information and contents, to create symbolic links, and to set compression and chunk size on a directory.                                                                    |
| <code>version</code>                                             | The <code>hadoop version</code> command prints the Hadoop software version.                                                                                                                                                                                                                                                               |

**Warning:** For Hadoop2, some `hadoop` commands are deprecated and replaced by the `mapred` command.

For example, if you run the `hadoop job` command, you see this message:

```
hadoop job
DEPRECATED: Use of this script to execute mapred command is deprecated.
Instead, use the mapred command for it.
```

The syntax for the `mapred` command is:

```
mapred [--config confdir] [--loglevel loglevel] COMMAND
```

Commands used with `mapred` include:

| Command                    | Description                                     |
|----------------------------|-------------------------------------------------|
| <code>historyserver</code> | Runs job history servers as a standalone daemon |

| Command | Description                            |
|---------|----------------------------------------|
| hsadmin | The job history server admin interface |
| job     | Manipulates MapReduce applications     |
| pipes   | Runs a pipes job                       |
| queue   | Gets information regarding JobQueues   |

### Generic Options

Implement the [Tool](#) interface to make the following command-line options available for many of the Hadoop commands.

| Generic Option                    | Description                                                                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| -conf <filename1 filename2 ...>   | Add the specified configuration files to the list of resources available in the configuration.                                          |
| -D <property=value>               | Set a value for the specified Hadoop configuration property.                                                                            |
| -fs <local filesystem URI>        | Set the URI of the default filesystem.                                                                                                  |
| -jt <local jobtracker:port>       | Specify a ResourceManager for a given host and port. This command option is a shortcut for <code>-D mapred.job.tracker=host:port</code> |
| -files <file1,file2,...>          | Specify files to be copied to the map reduce cluster.                                                                                   |
| -libjars <jar1,jar2,...>          | Specify JAR files to be included in the classpath of the mapper and reducer tasks.                                                      |
| -archives <archive1,archive2,...> | Specify archive files (JAR, tar, tar.gz, ZIP) to be copied and unarchived on the task node.                                             |

### hadoop archive

The `hadoop archive` command creates a Hadoop archive, a file that contains other files. A Hadoop archive always has a `*.har` extension.

### Syntax

```
hadoop [Generic Options] archive
 -archiveName <name>
 [-p <parent>]
 <source>
 <destination>
```

### Parameters

| Parameter           | Description                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------|
| -archiveName <name> | Name of the archive to be created.                                                            |
| -p <parent_path>    | The parent argument is to specify the relative path to which the files should be archived to. |

| Parameter     | Description                                                         |
|---------------|---------------------------------------------------------------------|
| <source>      | Filesystem pathnames, which work as usual with regular expressions. |
| <destination> | Destination directory, which would contain the archive.             |

## Examples

### Archive within a single directory

```
hadoop archive -archiveName myArchive.har -p /foo/bar /outputdir
```

The above command creates an archive of the directory `/foo/bar` in the directory `/outputdir`.

### Archive to another directory

```
hadoop archive -archiveName myArchive.har -p /foo/bar a/b/c e/f/g
```

The above command creates an archive of the directory `/foo/bar/a/b/c` in the directory `/foo/bar/e/f/g`.

### hadoop classpath

The `hadoop classpath` command prints the class path needed to access the Hadoop jar and the required libraries.

### Syntax

```
hadoop classpath
```

### Output Example

```
$hadoop classpath
/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop:/opt/mapr/hadoop/hadoop-2.7.0/
share/hadoop/common/lib/
/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/:/opt/mapr/hadoop/
hadoop-2.7.0/share/hadoo
p/hdfs:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/hdfs/lib/*:/opt/mapr/
hadoop/hadoop-2.7.0/shar
e/hadoop/hdfs/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/yarn/lib/*:/opt/
mapr/hadoop/hadoop-2
.7.0/share/hadoop/yarn/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/
mapreduce/lib/*:/opt/mapr/h
adoop/hadoop-2.7.0/share/hadoop/mapreduce/*:/contrib/capacity-scheduler/
*.jar:/opt/mapr/lib/kvs
tore*.jar:/opt/mapr/lib/libprotodefs*.jar:/opt/mapr/lib/baseutils*.jar:/opt/
mapr/lib/maprutil*.
jar:/opt/mapr/lib/json-20080701.jar:/opt/mapr/lib/flexjson-2.1.jar
```

### hadoop daemonlog

The `hadoop daemonlog` command gets and sets the log level for each daemon.

Hadoop daemons all produce logfiles that you can use to learn about what is happening on the system. You can use the `hadoop daemonlog` command to temporarily change the log level of a component when debugging the system.

## Syntax

```

hadoop daemonlog
 -getlevel | -setlevel
 <host>:<port>
 <name>
 [<level>]

```

## Parameters

The following command options are supported for `hadoop daemonlog` command:

| Parameter                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-getlevel &lt;host:port&gt;&lt;name&gt;</code>                | <p>Prints the log level of the daemon running at the specified host and port, by querying</p> <pre>http://&lt;host&gt;:&lt;port&gt;/logLevel?log=&lt;name&gt;</pre> <ul style="list-style-type: none"> <li>• <code>&lt;host&gt;</code>: The host on which to get the log level.</li> <li>• <code>&lt;port&gt;</code>: The port by which to get the log level.</li> <li>• <code>&lt;name&gt;</code>: The daemon on which to get the log level. Usually the fully qualified classname of the daemon doing the logging. For example, <code>org.apache.hadoop.yarn.server.resourcemanager.resourcemanager</code> for the Resource Manager daemon.</li> </ul> |
| <code>-setlevel &lt;host:port&gt; &lt;name&gt; &lt;level&gt;</code> | <p>Sets the log level of the daemon running at the specified host and port, by querying</p> <pre>http://&lt;host&gt;:&lt;port&gt;/logLevel?log=&lt;name&gt;</pre> <ul style="list-style-type: none"> <li>* <code>&lt;host&gt;</code>: The host on which to set the log level.</li> <li>• <code>&lt;port&gt;</code>: The port by which to set the log level.</li> <li>• <code>&lt;name&gt;</code>: The daemon on which to set the log level.</li> <li>• <code>&lt;level&gt;</code>: The log level to set the daemon.</li> </ul>                                                                                                                           |

## Examples

### Getting the log levels of a daemon

To get the log level for each daemon enter a command such as the following:

```

hadoop daemonlog -getlevel 10.250.1.15:50030
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Connecting to http://10.250.1.15:50030/logLevel?
log=org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Submitted Log Name:
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Log Class: org.apache.commons.logging.impl.Log4JLogger
Effective level: ALL

```

### Setting the log level of a daemon

To temporarily set the log level for a daemon enter a command such as the following:

```
hadoop daemonlog -setlevel 10.250.1.15:50030
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager DEBUG
Connecting to http://10.250.1.15:50030/logLevel?
log=org.apache.hadoop.yarn.server.resourcemanager.resourcemanager&level=DEBU
G
Submitted Log Name:
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Log Class: org.apache.commons.logging.impl.Log4JLogger
Submitted Level: DEBUG
Setting Level to DEBUG ...
Effective level: DEBUG
```

Using this method, the log level is automatically reset when the daemon is restarted.

To make the change to log level of a daemon persistent, enter a command such as the following:

```
hadoop daemonlog -setlevel 10.250.1.15:50030
log4j.logger.org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
DEBUG
```

### hadoop distcp

The `hadoop distcp` command is a tool used for large inter- and intra-cluster copying.

It uses MapReduce to effect its distribution, error handling and recovery, and reporting. It expands a list of files and directories into input to map tasks, each of which will copy a partition of the files specified in the source list.

### Syntax

```
hadoop [Generic Options] distcp
 [-p[erbugp]]
 [-i]
 [-log]
 [-m]
 [-overwrite]
 [-update]
 [-f <URI list>]
 [-filelimit <n>]
 [-sizelimit <n>]
 [-delete]
 <source>
 <destination>
```

### Parameters

#### Command Options

The following command options are supported for the `hadoop distcp` command:

| Parameter     | Description                  |
|---------------|------------------------------|
| <source>      | Specify the source URL.      |
| <destination> | Specify the destination URL. |

| Parameter                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-blocksperchunk</code><br><code>&lt;number-of-blocks-per-chunk&gt;</code> | Number of blocks per chunk. When specified, this option splits files into chunks to copy the files in parallel. If the option is set to a positive value, files with more blocks than this value are split into chunks of <code>&lt;number-of-blocks-per-chunk&gt;</code> blocks to be transferred in parallel and reassembled at the destination. By default, <code>&lt;number-of-blocks-per-chunk&gt;</code> is 0 and files are transmitted in their entirety without splitting. |
| <code>-p[erbugp]</code>                                                         | Preserve e: ACE r: replication number b: block size u: user g: group p: permission <code>-p</code> alone is equivalent to <code>-perbugp</code> . Modification times are not preserved. When you specify <code>-update</code> , status updates are not synchronized unless the file sizes also differ.                                                                                                                                                                             |
| <code>-i</code>                                                                 | Ignore failures. As explained in the below, this option will keep more accurate statistics about the copy than the default case. It also preserves logs from failed copies, which can be valuable for debugging. Finally, a failing map will not cause the job to fail before all splits are attempted.                                                                                                                                                                            |
| <code>-log &lt;logdir&gt;</code>                                                | Write logs to <code>&lt;logdir&gt;</code> . The <code>hadoop distcp</code> command keeps logs of each file it attempts to copy as map output. If a map fails, the log output will not be retained if it is re-executed.                                                                                                                                                                                                                                                            |
| <code>-m &lt;num_maps&gt;</code>                                                | Maximum number of simultaneous copies. Specify the number of maps to copy data. Note that more maps may not necessarily improve throughput. See <i>Map Sizing</i> .                                                                                                                                                                                                                                                                                                                |
| <code>-overwrite</code>                                                         | Overwrite destination. If a map fails and <code>-i</code> is not specified, all the files in the split, not only those that failed, will be recopied. As discussed in the <i>Overwriting Files Between Clusters</i> , it also changes the semantics for generating destination paths, so users should use this carefully.                                                                                                                                                          |
| <code>-update</code>                                                            | Overwrite if <code>&lt;source&gt;</code> size is different from <code>&lt;destination&gt;</code> size. As noted in the preceding, this is not a "sync" operation. The only criterion examined is the source and destination file sizes; if they differ, the source file replaces the destination file. See <i>Updating Files Between Clusters</i> .                                                                                                                                |
| <code>-f &lt;URI list&gt;</code>                                                | Use list at <code>&lt;URI list&gt;</code> as source list. This is equivalent to listing each source on the command line. The value of <code>&lt;URI list&gt;</code> must be a fully qualified URI.                                                                                                                                                                                                                                                                                 |
| <code>-filelimit &lt;n&gt;</code>                                               | Limit the total number of files to be $\leq n$ . See <i>Symbolic Representations</i> .                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-sizelimit &lt;n&gt;</code>                                               | Limit the total size to be $\leq n$ bytes. See <i>Symbolic Representations</i> .                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-delete</code>                                                            | Delete the files existing in the <code>&lt;destination&gt;</code> but not in <code>&lt;source&gt;</code> . The deletion is done by FS Shell.                                                                                                                                                                                                                                                                                                                                       |

### Generic Options

The `hadoop distcp` command supports the following generic options: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|file system URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see [Generic Options](#).

### Symbolic Representations

The parameter `<n>` in `-filelimit` and `-sizelimit` can be specified with symbolic representation. For example,

- $1230k = 1230 * 1024 = 1259520$
- $891g = 891 * 1024^3 = 956703965184$

## Map Sizing

The `hadoop distcp` command attempts to size each map comparably so that each copies roughly the same number of bytes. Note that files are the finest level of granularity, so increasing the number of simultaneous copiers (i.e. maps) may not always increase the number of simultaneous copies nor the overall throughput.

If `-m` is not specified, `distcp` will attempt to schedule work for `min (total_bytes / bytes.per.map, 20 * num_task_trackers)` where `bytes.per.map` defaults to 256MB.

Tuning the number of maps to the size of the source and destination clusters, the size of the copy, and the available bandwidth is recommended for long-running and regularly run jobs.

## Examples

For all of the below examples, the cluster name must be specified in the [mapr-clusters.conf](#) on page 2485 configuration file.

### Basic inter-cluster copying

The `hadoop distcp` command is most often used to copy files between clusters:

```
hadoop distcp maprfs://cluster1/foo \
maprfs://cluster2/bar
```

The command in the example expands the namespace under `/foo/bar` on cluster1 into a temporary file, partitions its contents among a set of map tasks, and starts a copy on each NodeManager node from cluster1 to cluster2. Note that the `hadoop distcp` command expects absolute paths.

Only those files that do not already exist in the destination are copied over from the source directory.

### Updating files between clusters

Use the `hadoop distcp -update` command to synchronize changes between clusters.

```
$ hadoop distcp -update maprfs://cluster1/foo maprfs://cluster2/bar/foo
```

Files in the `/foo` subtree are copied from cluster1 to cluster2 only if the size of the source file is different from that of the size of the destination file. Otherwise, the files are skipped over.

Note that using the `-update` option changes distributed copy interprets the source and destination paths making it necessary to add the trailing `/foo` subdirectory in the second cluster.

### Overwriting files between clusters

By default, distributed copy skips files that already exist in the destination directory, but you can overwrite those files using the `-overwrite` option. In this example, multiple source directories are specified:

```
$ hadoop distcp -overwrite maprfs://cluster1/foo/a \
maprfs://cluster1/foo/b \
maprfs://cluster2/bar
```

As with using the `-update` option, using the `-overwrite` changes the way that the source and destination paths are interpreted by distributed copy: the contents of the source directories are compared to the contents of the destination directory. The distributed copy aborts in case of a conflict.

### Migrating Data from HDFS to filesystem

The `hadoop distcp` command can be used to migrate data from an HDFS cluster to a filesystem where the HDFS cluster uses the same version of the RPC protocol as that used by MapR. For a discussion, see [Copying Data from Apache Hadoop](#).

```
$ hadoop distcp namenode1:50070/foo maprfs:///bar
```

You must specify the IP address and HTTP port (usually 50070) for the namenode on the HDFS cluster.

### hadoop fs

The `hadoop fs` command runs a generic file system user client that interacts with the filesystem. Starting from EEP 7.1.0, all `hadoop fs` commands support operations on symlinks.

**Warning:** On the Windows client, make sure that the `PATH` contains the following directories:

- C:\Windows\system32
- C:\Windows

If they are not present, the `hadoop fs` command might fail silently.

### Syntax

```
hadoop [Generic Options] fs
 [-cat <src>]
 [-chgrp [-R] GROUP PATH...]
 [-chmod [-R] <MODE[,MODE]... | OCTALMODE> PATH...]
 [-chown [-R] [OWNER][:[GROUP]] PATH...]
 [-copyFromLocal <localsrc> ... <dst>]
 [-copyToLocal [-ignoreCrc] [-crc] <src> <localdst>]
 [-count[-q] <path>]
 [-cp <src> <dst> -p[e]]
 [-df <path>]
 [-du <path>]
 [-dus <path>]
 [-expunge]
 [-get [-ignoreCrc] [-crc] <src> <localdst>]
 [-getfattr [-R] {-n name | -d} [-e <encoding>] <path>]
 [-getmerge <src> <localdst> [addnl]]
 [-help [cmd]]
 [-ls <path>]
 [-lsr <path>]
 [-mkdir <path>]
 [-moveFromLocal <localsrc> ... <dst>]
 [-moveToLocal <src> <localdst>]
 [-mv <src> <dst>]
 [-put <localsrc> ... <dst>]
 [-rm [-skipTrash] <src>]
 [-rmr [-skipTrash] <src>]
 [-setfattr -n name [-v value] | -x name <path>]
 [-stat [format] <path>]
 [-tail [-f] <path>]
 [-test -[ezd] <path>]
 [-text <path>]
 [-touchz <path>]
```

### Parameters

#### Command Options

The following command parameters are supported for `hadoop fs`:

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-cat &lt;src&gt;</code>                                                      | Fetch all files that match the file pattern defined by the <code>&lt;src&gt;</code> parameter and display their contents on <code>stdout</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-chmod [-R]<br/>&lt;MODE[,MODE]...  <br/>OCTALMODE&gt; PATH...</code>        | Changes permissions of a file. This works similar to shell's <code>chmod</code> with a few exceptions. <code>-R</code> modifies the files recursively. This is the only option currently supported. <code>MODE</code> Mode is same as mode used for <code>chmod</code> shell command. Only letters recognized are <code>rwXt</code> . That is, <code>+t, a+r, g-w, +rwx, o=r</code> <code>OCTALMODE</code> Mode specified in 3 or 4 digits. If 4 digits, the first may be 1 or 0 to turn the sticky bit on or off, respectively. Unlike shell command, it is not possible to specify only part of the mode E.g. <code>754</code> is same as <code>u=rwx,g=rx,o=r</code> If none of 'augo' is specified, 'a' is assumed and unlike shell command, no <code>umask</code> is applied.                               |
| <code>-chown [-R] [OWNER]<br/>[:[GROUP]] PATH...</code>                            | Changes owner and group of a file. This is similar to shell's <code>chown</code> with a few exceptions. <code>-R</code> modifies the files recursively. This is the only option currently supported. If only owner or group is specified then only owner or group is modified. The owner and group names may only consists of digits, alphabet, and any of <code>-.@/'</code> i.e. <code>[-.@a-zA-Z0-9]</code> . The names are case sensitive.<br><br> <b>Warning:</b> Avoid using <code>'</code> to separate user name and group though Linux allows it. If user names have dots in them and you are using local file system, you might see surprising results since shell command <code>chown</code> is used for local files. |
| <code>-chgrp [-R] GROUP<br/>PATH...</code>                                         | This is equivalent to <code>-chown ... :GROUP ...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-copyFromLocal<br/>&lt;localsrc&gt; ... &lt;dst&gt;</code>                   | Identical to the <code>-put</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-copyToLocal<br/>[-ignoreCrc] [-crc]<br/>&lt;src&gt; &lt;localdst&gt;</code> | Identical to the <code>-get</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-count[-q] &lt;path&gt;</code>                                               | Count the number of directories, files and bytes under the paths that match the specified file pattern. The output columns are: <code>DIR_COUNT FILE_COUNT CONTENT_SIZE FILE_NAME</code> or <code>QUOTA REMAINING_QUOTA SPACE_QUOTA REMAINING_SPACE_QUOTA DIR_COUNT FILE_COUNT CONTENT_SIZE FILE_NAME</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-cp &lt;src&gt; &lt;dst&gt;<br/>[-p[e]]</code>                               | Copy files that match the file pattern <code>&lt;src&gt;</code> to a destination. When copying multiple files, the destination must be a directory. Specifying <code>-p</code> with the <code>e</code> option preserves an ACE applied to the file. Specifying <code>-p</code> without an argument preserves the ACE by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-df [&lt;path&gt;]</code>                                                    | Shows the capacity, free and used space of the file system. If the file system has multiple partitions, and no path to a particular partition is specified, then the status of the root partitions will be shown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-du &lt;path&gt;</code>                                                      | Show the amount of space, in bytes, used by the files that match the specified file pattern. Equivalent to the Unix command <code>du -sb &lt;path&gt;/*</code> in case of a directory, and to <code>du -b &lt;path&gt;</code> in case of a file. The output is in the form <code>name(full path) size (in bytes)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-dus &lt;path&gt;</code>                                                     | Show the amount of space, in bytes, used by the files that match the specified file pattern. Equivalent to the Unix command <code>du -sb</code> . The output is in the form <code>name(full path) size (in bytes)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

An error is returned if the file exists with non-zero length.                                                                                                                                                                                                                                                                                                                                                                             |                              |                                            |                               |                                             |                              |                                               |                           |                        |
| <code>-test -[ezd] &lt;path&gt;</code>                                                   | If file { exists, has zero length, is a directory then return 0, else return 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                              |                                            |                               |                                             |                              |                                               |                           |                        |
| <code>-text &lt;src&gt;</code>                                                           | Takes a source file and outputs the file in text format. The allowed formats are zip and TextRecordInputStream.                                                                                                                                                                                                                                                                                                                                                                                                                                 |                              |                                            |                               |                                             |                              |                                               |                           |                        |

## Generic Options

The following generic options are supported for the `hadoop fs` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|file system URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see [Generic Options](#).

## Examples

### Set an extended attribute on a file, file1.txt:

```
hadoop fs -setfattr -n user.key1 -v val1 /xattrs/m7user1/file1.txt
```

### Remove an extended attribute specified by name:

```
hadoop fs -setfattr -x user.key1 /xattrs/m7user1/dirl
```

### Retrieve an extended attribute for a file encoded in text:

```
[root@qa-nodell10 ~]# hadoop fs -getfattr -n user.key1 -e text /xattr/file1
file: /xattr/file1
user.key1="value1"
```

**Retrieve an extended attribute for a file encoded in hex:**

```
[root@qa-nodell10 ~]# hadoop fs -getfattr -n user.key1 -e hex /xattr/file1
file: /xattr/file1
user.key1=0x76616c756531
```

**Retrieve an extended attribute for a file encoded in base64:**

```
[root@qa-nodell10 ~]# hadoop fs -getfattr -n user.key1 -e base64 /xattr/file1
file: /xattr/file1
user.key1=0sdmFsdWUx
```

**Retrieve an extended attribute specified by name:**

```
[root@qa-nodell10 ~]# hadoop fs -getfattr -n user.key1 /xattr/file2
file: /xattr/file2
user.key1="value1"
```

**Retrieve all the extended attributes associated with the given file:**

```
[root@qa-nodell10 ~]# hadoop fs -getfattr -d /xattr/file2
file: /xattr/file2
user.key2="value2"
user.key1="value1"
```

**Retrieve extended attributes recursively:**

```
[root@qa-nodell10 ~]# hadoop fs -getfattr -R -d /xattr/
file: /xattr
file: /xattr/file1
user.key2="value2"
file: /xattr/file2
user.key2="value2"
user.key1="value1"
```

**Retrieve a specific extended attribute recursively on a directory:**

```
[root@qa-nodell10 ~]# hadoop fs -getfattr -R -n user.key1 /xattr/
file: /xattr
user.key1="value1"
file: /xattr/file1
getfattr: No such attribute
file: /xattr/file2
user.key1="value1"
```

**Suppressing Warning Messages for the hadoop fs Command**

After an upgrade to 4.0.x, the `hadoop fs` command returns the following warning message:

```
WARNING: org.apache.hadoop.metrics.jvm.EventCounter is deprecated. Please
use
org.apache.hadoop.log.metrics.EventCounter in all the log4j.properties
files.
```

This message does not cause any problems, but you can suppress it by modifying the following file:

```
/opt/mapr/hadoop/hadoop-0.20.2/conf/log4j.properties
```

In this file, replace the following line:

```
log4j.appender.EventCounter=org.apache.hadoop.log.EventCounter
```

with this line:

```
log4j.appender.EventCounter=org.apache.hadoop.log.metrics.EventCounter
```

### hadoop jar

The `hadoop jar` command runs a program contained in a JAR file. Users can bundle their MapReduce code in a JAR file and execute it using this command.

### Syntax

```
hadoop jar <jar>
 [<arguments>]
```

### Parameters

The following commands parameters are supported for `hadoop jar`:

| Parameter   | Description                                         |
|-------------|-----------------------------------------------------|
| <jar>       | The JAR file.                                       |
| <arguments> | Arguments to the program specified in the JAR file. |

### Examples

#### Streaming Application

Hadoop streaming applications are run using the `hadoop jar` command. The Hadoop streaming utility enables you to create and run MapReduce applications with any executable or script as the mapper and/or the reducer.

```
$ hadoop jar $HADOOP_HOME/hadoop-streaming.jar \
 -input myInputDirs \
 -output myOutputDir \
 -mapper org.apache.hadoop.mapred.lib.IdentityMapper \
 -reducer /bin/wc
```

The `-input`, `-output`, `-mapper`, and `-reducer` streaming command options are all required for streaming jobs. Either an executable or a Java class may be used for the mapper and the reducer. For more information about and examples of streaming applications, see [Hadoop Streaming](#) at the Apache project's page.

#### Running from a JAR file

The simple Word Count program is another example of a program that is run using the `hadoop jar` command. The `wordcount` functionality is built into the `hadoop-0.20.2-dev-examples.jar` program. You pass the file, along with the location, to Hadoop with the `hadoop jar` command and Hadoop reads the JAR file and executes the relevant instructions.

The Word Count program reads files from an input directory, counts the words, and writes the results of the application to files in an output directory.

```
$ hadoop jar /opt/mapr/hadoop/hadoop-0.20.2/hadoop-0.20.2-dev-examples.jar
wordcount /myvolume/in /myvolume/out
```

### hadoop job

The `hadoop job` command enables you to manage MapReduce jobs.

**Warning:** This command is deprecated.

## Syntax

```

hadoop job [Generic Options]
 [-submit <job-file>]
 [-status <job-id>]
 [-counter <job-id> <group-name> <counter-name>]
 [-kill <job-id>]
 [-unblacklist <job-id> <hostname>]
 [-unblacklist-tracker <hostname>]
 [-set-priority <job-id> <priority>]
 [-events <job-id> <from-event-#> <#-of-events>]
 [-history <jobOutputDir>]
 [-list [all]]
 [-list-active-trackers]
 [-list-blacklisted-trackers]
 [-list-attempt-ids <job-id> <task-type> <task-state>]
 [-kill-task <task-id>]
 [-fail-task <task-id>]
 [-blacklist-tasktracker <hostname>]
 [-showlabels]

```

## Parameters

### Command Options

The following command options are supported for `hadoop job`:

| Parameter                                                                    | Description                                                                                                                                                                                                                                                     |
|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-submit &lt;job-file&gt;</code>                                        | Submits the job.                                                                                                                                                                                                                                                |
| <code>-status &lt;job-id&gt;</code>                                          | Prints the map and reduce completion percentage and all job counters.                                                                                                                                                                                           |
| <code>-counter &lt;job-id&gt; &lt;group-name&gt; &lt;counter-name&gt;</code> | Prints the counter value.                                                                                                                                                                                                                                       |
| <code>-kill &lt;job-id&gt;</code>                                            | Kills the job.                                                                                                                                                                                                                                                  |
| <code>-unblacklist &lt;job-id&gt; &lt;hostname&gt;</code>                    | Removes a tasktracker job from the jobtracker's blacklist.                                                                                                                                                                                                      |
| <code>-unblacklist-tracker &lt;hostname&gt;</code>                           | Admin only. Removes the TaskTracker at <hostname> from the JobTracker's global blacklist.                                                                                                                                                                       |
| <code>-set-priority &lt;job-id&gt; &lt;priority&gt;</code>                   | Changes the priority of the job. Valid priority values are <code>VERY_HIGH</code> , <code>HIGH</code> , <code>NORMAL</code> , <code>LOW</code> , and <code>VERY_LOW</code> . The job scheduler uses this property to determine the order in which jobs are run. |
| <code>-events &lt;job-id&gt; &lt;from-event-#&gt; &lt;#-of-events&gt;</code> | Prints the events' details received by jobtracker for the given range.                                                                                                                                                                                          |
| <code>-history &lt;jobOutputDir&gt;</code>                                   | Prints job details, failed and killed tip details.                                                                                                                                                                                                              |
| <code>-list [all]</code>                                                     | The <code>-list all</code> option displays all jobs. The <code>-list</code> command without the <code>all</code> option displays only jobs which are yet to complete.                                                                                           |
| <code>-list-active-trackers</code>                                           | Prints all active tasktrackers.                                                                                                                                                                                                                                 |

| Parameter                                                      | Description                                                                                              |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>-list-blackisted-trackers</code>                         | Prints the TaskTracker nodes that JobTracker blacklisted with the reason for blacklisting.               |
| <code>-list-attempt-ids &lt;job-id&gt;&lt;task-type&gt;</code> | Lists the IDs of task attempts.                                                                          |
| <code>-kill-task &lt;task-id&gt;</code>                        | Kills the task. Killed tasks are <i>not</i> counted against failed attempts.                             |
| <code>-fail-task &lt;task-id&gt;</code>                        | Fails the task. Failed tasks are counted against failed attempts.                                        |
| <code>-blacklist-tasktracker &lt;hostname&gt;</code>           | Pauses all current tasktracker jobs and prevent additional jobs from being scheduled on the tasktracker. |
| <code>-showlabels</code>                                       | Dumps label information of all active nodes.                                                             |

### Generic Options

The following generic options are supported for the `hadoop job` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|file system URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see [Generic Options](#).

### Examples

#### Submitting Jobs

The `hadoop job -submit` command enables you to submit a job to the specified jobtracker.

```
$ hadoop job -jt darwin:50020 -submit job.xml
```

#### Stopping Jobs Gracefully

Use the `hadoop kill` command to stop a running or queued job.

```
$ hadoop job -kill <job-id>
```

#### Viewing Job History Logs

Run the `hadoop job -history` command to view the history logs summary in specified directory.

```
$ hadoop job -history output-dir
```

This command will print job details, failed and killed tip details.

Additional details about the job such as successful tasks and task attempts made for each task can be viewed by adding the `-all` option:

```
$ hadoop job -history all output-dir
```

#### Blacklisting Tasktrackers

The `hadoop job` command when run as root or using `sudo` can be used to manually blacklist tasktrackers:

```
hadoop job -blacklist-tasktracker <hostname>
```

Manually blacklisting a tasktracker pauses any running jobs and prevents additional jobs from being scheduled.

### hadoop mfs

The `hadoop mfs` command displays directory information and contents, creates symbolic links and hard links, sets, gets, and removes Access Control Expressions (ACE) on files and directories, and sets compression and chunk size on a directory.

### Syntax

```
hadoop mfs
 [-count <path>]
 [-delace [-R] <path>]
 [-getace [-R] <path>]
 [-help <command>]
 [-ln <target> <symlink>]
 [-lnh <target> <hardlink>]
 [-ls <path>]
 [-lsd <path>]
 [-lsf <path>]
 [-lso <path>]
 [-lsor <path>]
 [-lsr <path>]
 [-Lsr <path>]
 [-lsrv <path>]
 [-lss <path>]
 [-offload <file_path> [-v]]
 [-recall <file_path> [-v]]
 [-rmr <path>]
 [-setace [-R]
 [-readfile <ace>] [-writefile <ace>] [-executefile <ace>]
 [-addchild <ace>] [-deletechild <ace>] [-lookupdir <ace>] [-readdir
 <ace>]
 [-aces "[rf:<ace>],[wf:<ace>],[ef:<ace>],[ac:<ace>],[dc:<ace>],
 [rd:<ace>],[ld:<ace>]"]
 [-preservemodebits <true|false>] [-setinherit <true|false>] <path>]
 [-setaudit on|off <dir|file|table>]
 [-setcompression on|off|lzf|lz4|zlib <dir|table>]
 [-setchunksize <size> <dir>]

 [-setnetworkencryption on|off <target>]
 [-stat <path>]
 [-tierstatus <file_path> [-v]]
 [-addsecuritypolicytag [-R] <comma-separated list of security policy
 tags> <path>]
 [-getsecuritypolicytag [-R] <path>]
 [-removesecuritypolicytag [-R] <comma-separated list of security policy
 tags> <path>]
 [-removeallsecuritypolicytag [-R] <path>]
 [-setsecuritypolicytag [-R] <comma-separated list of security policy
 tags> <path>]
```

### Parameters

The normal command syntax is to specify a single option from the following table, along with its corresponding arguments. If you do not set compression and chunk size for a given directory, the values are inherited from the parent directory.

| Parameter                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                             |                                                             |                               |                                                              |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|-------------------------------------------------------------|-------------------------------|--------------------------------------------------------------|
| <code>-count &lt;path&gt;</code>                  | Counts and returns the number of directories and (regular, symbolic link, volume link, kvstores, and device) files in the specified path (recursively).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                             |                                                             |                               |                                                              |
| <code>-delace [-R] &lt;path&gt;</code>            | <p>Deletes all <a href="#">ACEs</a> associated with the specified file or directory and sets <a href="#">ACEs</a> for the specified file or directory to the default value, which is the empty string. Here:</p> <ul style="list-style-type: none"> <li><code>[-R]</code> — Enables recursion allowing you to perform the operation in subdirectories as well.</li> <li><code>&lt;path&gt;</code> — Specifies the path to the file or directory.</li> </ul> <p>You cannot delete specific access types with this parameter. Instead, if necessary, reset the value for the specific access type to an empty string using the <code>-setace</code> parameter. If you use an empty string to deny a specific type of access, then that type of access is denied to all users. To deny specific types of access to specific users only, use the negation operator (!). The mode bits corresponding to the <a href="#">ACEs</a> being deleted, do not change.</p> |                             |                                                             |                               |                                                              |
| <code>-getace [-R] &lt;path&gt;</code>            | <p>Returns the permissions -- POSIX mode bits and <a href="#">ACEs</a> -- for the given file or (recursively) for the directory. Recursion is enabled only if -R is specified; if -R is not specified, this parameter returns the permissions only for the given directory. Here:</p> <ul style="list-style-type: none"> <li><code>[-R]</code> — (Optional) Enables recursion allowing you to perform the operation in subdirectories as well.</li> <li><code>&lt;path&gt;</code> — (Required) Specifies the path to the file or directory.</li> </ul> <p>If one or more <a href="#">ACEs</a> are available for the file or directory, a plus sign (+), which indicates that both <a href="#">ACEs</a> and POSIX mode bits are set for the given file or directory, is returned. If the <a href="#">ACE</a> on the file or directory is an empty string, the plus sign is not returned.</p>                                                                   |                             |                                                             |                               |                                                              |
| <code>-help &lt;command&gt;</code>                | Displays help for the <code>hadoop mfs</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                             |                                                             |                               |                                                              |
| <code>-ln &lt;target&gt; &lt;symlink&gt;</code>   | Creates a symbolic link <code>&lt;symlink&gt;</code> that points to the target path <code>&lt;target&gt;</code> , similar to the standard Linux <code>ln -s</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                             |                                                             |                               |                                                              |
| <code>-lnh &lt;target&gt; &lt;hardlink&gt;</code> | <p>Creates a hardlink that associates a new name or a file path with an existing file. You must specify the following:</p> <table border="0"> <tr> <td><code>&lt;target&gt;</code></td> <td>File name, including the full path, of the file to link to.</td> </tr> <tr> <td><code>&lt;hardlink&gt;</code></td> <td>New name, including the full path, of the file to link with.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <code>&lt;target&gt;</code> | File name, including the full path, of the file to link to. | <code>&lt;hardlink&gt;</code> | New name, including the full path, of the file to link with. |
| <code>&lt;target&gt;</code>                       | File name, including the full path, of the file to link to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                             |                                                             |                               |                                                              |
| <code>&lt;hardlink&gt;</code>                     | New name, including the full path, of the file to link with.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                             |                                                             |                               |                                                              |

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-ls &lt;path&gt;</code>   | <p>Lists files in the directory specified by <code>&lt;path&gt;</code>. The <code>hadoop mfs -ls</code> command corresponds to the standard <code>hadoop fs -ls</code> command, but provides the following additional information:</p> <ul style="list-style-type: none"> <li>• Chunks used for each file</li> <li>• Server where each chunk resides</li> <li>• Whether compression is enabled for each file</li> <li>• Whether encryption is enabled for each file</li> <li>• Whether audit is enabled (A) or disabled (U) for each file</li> </ul>                                                |
| <code>-lsd &lt;path&gt;</code>  | <p>Lists files in the directory specified by <code>&lt;path&gt;</code>, and also provides information about the specified directory itself:</p> <ul style="list-style-type: none"> <li>• Whether compression is enabled for the directory (indicated by <code>z</code>)</li> <li>• The configured chunk size (in bytes) for the directory.</li> </ul>                                                                                                                                                                                                                                               |
| <code>-lsf &lt;path&gt;</code>  | <p>Lists just the file ID (fid) and the file name, for each file present in the specified path. The output is not sorted.</p> <p>Use this option when there are millions of files in a directory. In this scenario, using this option results in the fastest listing of files, as only the fids and the file names are returned. All other file attributes are ignored.</p>                                                                                                                                                                                                                         |
| <code>-lso &lt;path&gt;</code>  | <p>Lists files in the directory specified by <code>&lt;path&gt;</code>. The <code>hadoop mfs -lso</code> command corresponds to the standard <code>hadoop fs -ls</code> command, but provides the following additional information:</p> <ul style="list-style-type: none"> <li>• Whether compression is enabled for each file</li> <li>• Whether encryption is enabled for each file</li> <li>• Whether audit is enabled (A) or disabled (U) for each file</li> </ul> <p>This command is faster than <code>hadoop fs -ls</code> as it uses an optimized printing method to dump data on screen.</p> |
| <code>-lsor &lt;path&gt;</code> | <p>Recursively lists files in the directory specified by <code>&lt;path&gt;</code>. This command is the recursive variant of the <code>hadoop mfs -lso</code> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-lsr &lt;path&gt;</code>  | <p>Recursively lists files in the directory and subdirectories specified by <code>&lt;path&gt;</code>. The <code>hadoop mfs -lsr</code> command corresponds to the standard <code>hadoop fs -lsr</code> command, but provides the following additional information:</p> <ul style="list-style-type: none"> <li>• Chunks used for each file</li> <li>• Server where each chunk resides</li> </ul>                                                                                                                                                                                                    |
| <code>-Lsr &lt;path&gt;</code>  | <p>Equivalent to <code>lsr</code>, but additionally dereferences symbolic links</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-lsrv &lt;path&gt;</code>              | Lists all paths recursively without crossing volume links.                                                                                                                                                                                                                                                        |
| <code>-lss &lt;path&gt;</code>               | Lists files in the directory specified by <code>&lt;path&gt;</code> , with an additional column that displays the number of disk blocks per file. Disk blocks are 8192 bytes.                                                                                                                                     |
| <code>-offload &lt;file_path&gt; [-v]</code> | The file to offload to the storage tier. This is a blocking operation; the control is not returned until the operation is complete and the file has been offloaded. Use <code>-v</code> (for verbose) to view the status of the ongoing offload operation.                                                        |
| <code>-recall &lt;file_path&gt; [-v]</code>  | The file to recall from the storage tier. This is a blocking operation; the control is not returned until the operation is complete and the file has been recalled. Use <code>-v</code> (for verbose) to view the status of the ongoing recall operation.                                                         |
| <code>-rmr &lt;path&gt;</code>               | Recursively deletes files and directories in the specified path. This is a highly optimized version of the normal generic <code>hadoop fs rmr</code> command and is 10X faster for large directories. This option is useful when one or more directories in the specified path contains many (millions of) files. |

| Parameter                                                                                                                                                                                                                                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |    |                             |    |                             |    |                               |

| <code>-setaudit on off &lt;dir file table&gt;</code>               | <p>Enables auditing of the specified directory, file, or HPE Ezmeral Data Fabric Database table.</p> <p>Enabling auditing of a directory does not enable auditing of files and subdirectories that exist in the directory. You must enable auditing on those existing files and subdirectories. However, any new files and subdirectories that you create will automatically be enabled for auditing. See <a href="#">How Does Auditing Work?</a> on page 835.</p> <p>For operations on the object to be logged, auditing also needs to be enabled on the cluster and the volume in which the object is located. See <a href="#">Managing Auditing</a> on page 832 for details. If auditing is enabled for a directory, new files and directories created within that directory are also enabled for auditing.</p> |

If <code>-v</code> (for verbose) is also specified, for the given file, the command specifies whether data is local or offloaded as the final output. If the file:</p> <ul style="list-style-type: none"> <li>Contains local data, returns the following final output: <pre>File has local data</pre> </li> <li>Is completely offloaded, returns the following final output: <pre>File does not have local data</pre> </li> </ul> <p>See <a href="#">Output</a> on page 5582 for more information.</p> |
| <code>-addsecuritypolicytag [-R] &lt;comma-separated list of security policy tags&gt; &lt;path&gt;</code>    | Adds a comma-separated list of security policy tags to the list of existing security policy (if any) for the file or directory specified in <i>path</i> . If the <i>path</i> is a directory, use the <code>-R</code> option to add the list of the security policy tags recursively for all files and subdirectories under that directory.                                                                                                                                                                                                                       |
| <code>-getsecuritypolicytag [-R] &lt;path&gt;</code>                                                         | Retrieves the security policy tags for the file or directory specified in <i>path</i> . If the <i>path</i> is a directory, use the <code>-R</code> option to retrieve the security policy tags for all files and subdirectories under that directory.                                                                                                                                                                                                                                                                                                            |
| <code>-removesecuritypolicytag [-R] &lt;comma-separated list of security policy tags&gt; &lt;path&gt;</code> | Removes one or more security policy tags from the list of existing security policy tags (if any) for the file or directory specified in <i>path</i> . If the <i>path</i> is a directory, use the <code>-R</code> option to recursively remove the specified security policy tags from all files and subdirectories under that directory.                                                                                                                                                                                                                         |
| <code>-removeallsecuritypolicytag [-R] &lt;path&gt;</code>                                                   | Removes all security policies tagged to the file or directory specified by <i>path</i> . If the <i>path</i> is a directory, use the <code>-R</code> option to recursively remove all security policy tags from all files and subdirectories under that directory.                                                                                                                                                                                                                                                                                                |
| <code>-setsecuritypolicytag [-R] &lt;comma-separated list of security policy tags&gt; &lt;path&gt;</code>    | Sets a comma-separated list security policy tags for the file or directory specified in <i>path</i> , replacing any existing security policy tags. If the <i>path</i> is a directory, use the <code>-R</code> option to recursively set the security policy tags on all files and subdirectories under that directory.                                                                                                                                                                                                                                           |

## Output

**When used with the `-ls`, `-lsd`, `-lso`, `-lsor`, `-lsr`, or `-lss` options**, `hadoop mfs` displays information about files and directories. For each file or directory `hadoop mfs` displays a line of basic information followed by lines listing the chunks that make up the file, in the following format:

```
{mode} {compression} {encryption} {audit} {diskFlush} {replication} {owner}
{group} {size} {date} {chunk size} {name} {chunk} {fid} {host} [{host}...]
{chunk} {fid} {host} [{host}...] ...
```

Volume links are displayed as follows:

```
{mode} {compression} {encryption} {audit} {diskFlush} {replication} {owner}
{group} {size} {date} {chunk size} {name} {chunk} {target volume name}
{writability} {fid} -> {fid} [{host}...] ...
```

The following table describes the values:

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mode               | A text string indicating the read, write, and execute permissions for the owner, group, and other permissions. See also <a href="#">Managing Permissions</a> on page 830.                                                                                                                                                                                                                                                                                           |

| replication        | The replication factor of the file (directories display a dash instead)                                                                                                                                                                                                                                                                                                                                                                                             |
| owner              | The owner of the file or directory                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| group              | The group of the file of directory                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| size               | The size of the file or directory                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| date               | The date the file or directory was last modified                                                                                                                                                                                                                                                                                                                                                                                                                    |
| chunk size         | The chunk size of the file or directory                                                                                                                                                                                                                                                                                                                                                                                                                             |
| name               | The name of the file or directory                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| chunk              | The chunk number. The first chunk is a primary chunk labeled "p", a 64K chunk containing the root of the file. Subsequent chunks are numbered in order.                                                                                                                                                                                                                                                                                                             |
| fid                | <p>The chunk's file ID, which consists of three parts:</p> <ul style="list-style-type: none"> <li>• The ID of the container where the file is stored</li> <li>• The inode of the file within the container</li> <li>• An internal version number</li> </ul> <p>For volume links, the first <code>fid</code> is the chunk that stores the volume link itself; the <code>fid</code> after the arrow (<code>-&gt;</code>) is the first chunk in the target volume.</p> |
| host               | The host on which the chunk resides. When several hosts are listed, the first host is the first copy of the chunk, while subsequent hosts are replicas.                                                                                                                                                                                                                                                                                                             |
| target volume name | The name of the volume pointed to by a volume link.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| writability        | Displays whether the volume is writable.                                                                                                                                                                                                                                                                                                                                                                                                                            |

**When used with the `-lsf <path>option`, `hadoop mfs` displays only the file ID (fid) and the file name of each file in the path.**

**When used with the `-stat <path>option`, `hadoop mfs` displays statistics for the given file. For each file, it displays the following:**

| Output field      | Description                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| uid               | The user ID of the owner.                                                                                                                                                                  |
|                   | The last access time.<br>The may not always be updated. For more information, see the <code>UpdateTimeInterval</code> entry in <a href="#">volume create</a> on page 2190.                 |
| mtime             | The last modified time.                                                                                                                                                                    |
| nlink             | The number of hard links.                                                                                                                                                                  |
| type              | The type of the file. Value can be one of: <ul style="list-style-type: none"> <li>regular</li> <li>directory</li> <li>symlink</li> <li>vollink</li> <li>kvstore</li> <li>device</li> </ul> |
| size              | The size of the file or directory. Depending on the type of file, it can be the actual size or the number of entries.                                                                      |
| mode              | The UNIX style permission mode bits for the file/directory.                                                                                                                                |
| networkencryption | The network encryption setting. Determines whether network encryption is enabled for this file.                                                                                            |

| Output field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subtype      | <p>The subtype for the specified type. The following subtypes are supported for some of the types:</p> <ul style="list-style-type: none"> <li><b>regular</b> <ul style="list-style-type: none"> <li>• FSTRegBucket</li> <li>• FSTRegCF</li> <li>• FSTRegKeyMap</li> </ul> </li> <li><b>kvstore</b> <ul style="list-style-type: none"> <li>• FSTKvTable</li> <li>• FSTKvTabletMap</li> <li>• FSTKvSchema</li> <li>• FSTKvTablet</li> <li>• FSTKvSegMap</li> <li>• FSTKvSpillMap</li> <li>• FSTKvKeyMap</li> <li>• FSTKvXattr</li> </ul> </li> <li><b>device</b> <ul style="list-style-type: none"> <li>• FSTDevPipe</li> <li>• FSTDevSocket</li> <li>• FSTDevBlock</li> <li>• FSTDevChar</li> </ul> </li> </ul> <p>For all other types, subtypes are not valid.</p> |
| gid          | The group ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| compression  | The compression setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

When used with [tierstatus](#), the output varies based on whether or not data is local, was offloaded, or was recalled. The output looks similar to the following if:

- Data was completely offloaded:

```
File does not have local data
```

- Data could not be completely offloaded or data was recalled:

```
File has local data
```

## Examples

### View File Information

The `hadoop mfs` command is used to view file contents. You can use this command to check if compression is turned off in a directory or mounted volume. For example,

```
hadoop mfs -ls /
Found 121 items
```

```

vrwxr-xr-x Z E U U 3 mapr mapr 121 2018-08-10 01:07
268435456 /.rw
 p mapr.cluster.root writeable 2049.50.131362 -> 2049.16.2
physical19.qa.lab:5660 physical20.qa.lab:5660 physical23.qa.lab:5660
vrwxr-xr-x Z E U U 3 root root 1 2018-08-09 19:26 268435456 /

 p 2049.102.131466 physical19.qa.lab:5660 physical20.qa.lab:5660
physical23.qa.lab:5660
...

```

In the preceding example, the letter `z` indicates LZ4 compression on the directory; the letter `U` indicates that the directory is uncompressed. In the following example, the listed item is both uncompressed (first `U`) and unencrypted (second `U`).

```

[root@node1-302 ~]# hadoop mfs -ls /hbase
Found 10 items
drwxr-xr-x Z E U U - root root 1 2018-08-09 19:26 268435456 /
ATS-VOL1533867958/data1533867963
 p 2322.32.131374 physical20.qa.lab:5660 physical19.qa.lab:5660
physical22.qa.lab:5660
...

```

The following example demonstrates the usage of the `-lsf` option:

```

[root@vm5 logs]# hadoop mfs -lsf /tmp/
 2050.33.262504 /tmp/hosts1
 2050.32.262502 /tmp/hosts2
 2050.35.393704 /tmp/hosts3

```

## Set ACEs

**Example 1:** The following command shows how to set separate read, write, and execute permissions (using [ACE](#)) on a file:

```

hadoop mfs -setace -readfile p -writefile 'g:group1&!u:user1' -executefile
p /file

```

When the command shown above runs, the POSIX mode bits for:

- Read access is set for owner, owning group, and others.
- Write access is set for none.
- Execute access is set for owner, owning group, others.

All other POSIX mode bits are set to 0.

**Example 2:** The following command shows how to set read, write, and execute permissions (using [ACE](#)) as a single string on the specified directory and force all files and subdirectories under the specified directory to inherit the parent [ACE](#). [ACEs](#) that are not specified will be set to the empty string.

```

hadoop mfs -setace -aces "rf:u:root,wf:group1&!
user1,ef:p,rd:u:m7user1" -setinherit true /dir

```

When the command shown above runs, the POSIX mode bits for listing the contents (r) of the directory is set for owner/user and all other POSIX mode bits on the directory are set to 0; all new directories under this directory will inherit the parent POSIX mode bits. Also, new files in the directory will inherit the following POSIX mode bits:

- Read access is set to owner/user.
- Write access is set to none.
- Execute access set for others.

All other POSIX mode bits are set to 0.

**Example 3:** The following command shows how to set permissions (using [ACE](#)) as a single string on the specified directory and all the files and subdirectories recursively.

```
hadoop mfs -setace -R -aces "rf:p,wf:g:group1&!
u:user1,ef:p" -preservemodebits true /dir
```

When the command shown above runs, the POSIX mode bits are not modified to match the [ACE](#) setting.

**Example 4:** The following command shows how to deny a specific type of access, `writefile`, which was set in the first example above, without removing all other access types associated with the file. The empty string used in the following example will deny write access to all users, [roles](#), and groups.

```
hadoop mfs -setace -writefile "" -preservemodebits false /file
```

When the command shown above runs, the POSIX mode bit for writing to the file is set to 0.

### Get ACEs

The following command shows the [ACEs](#) and POSIX mode bits for the specified file only.

```
hadoop mfs -getace /m7user1/file1.txt
```

### Output

```
Path: /m7user1/file1.txt
readfile: !u:m7user1
writefile: !u:m7user1
executefile: !u:m7user1
mode: -----
```

### Delete ACEs

The following command deletes all [ACEs](#) associated with the specified file and sets the ACE for the file to the empty string.

```
hadoop mfs -delace /file
```

The following command deletes all [ACEs](#) associated with the specified directory.

```
hadoop mfs -delace /dir
```

The following command deletes all [ACEs](#) associated with the specified directory and [ACEs](#) associated with the files and directories (recursively) below the specified directory.

```
hadoop mfs -delace -R /dir
```

### Create a Hard Link to File

The following command shows how to create a hard link to the file, file1, using a new name, file2.

```
hadoop mfs -lnh /madvoll/file1 /madvoll/file2
Creating Hardlink: /madvoll/file2 -> /madvoll/file1
```

### Retrieve the Number of Hard Links

The following command shows how to retrieve the number of hard links (and other statistics) associated with a given file.

```
hadoop mfs -stat /voll/file1
Path: /voll/file1
 fid: 23185.32.131232
 uid: root
 gid: root
 atime: 2016-06-29 18:49:03
 mtime: 2016-07-01 18:01:54
 nlink: 2
 type: FTRegular
 subtype: FSTInval
 size: 1024000000
 blocksize: 268435456
 mode: 644
 networkencryption: false
 compression: off
```

### View the status of the offload or recall operation for the file named file2 in volume named vol1:

```
hadoop mfs -tierstatus /voll/file2
File has local data.
```

### View the status of file named test1 in volume named vol1:

```
hadoop mfs -tierstatus /voll/test1 -v
 FID Has Local Data
2154.109.1049824 Yes
2172.143.524906 Yes
2172.153.524926 Yes
2172.166.524952 Yes
2172.167.524954 Yes
File has local data.
```

### Tag a file with a security policy:

The following command tags the file /user/root/javax.servlet-3.0.jar with three security policies, namely pci, hipaa, and new

```
hadoop mfs -setsecuritypolicytag pci,hippa,new /user/root/
javax.servlet-3.0.jar
```

### Retrieve security policy tags from a file:

```
hadoop mfs -getsecuritypolicytag /user/root/javax.servlet-3.0.jar
[hippa, new, pci]
```

### Remove all security policy tags from a file:

```
hadoop mfs -removeallsecuritypolicytag /user/root/javax.servlet-3.0.jar
```

**hadoop mradmin**

The `hadoop mradmin` command runs Map-Reduce administrative commands.

 **Warning:** This command is deprecated.

**Syntax**

```
hadoop [Generic Options] mradmin
 [-refreshServiceAcl]
 [-refreshQueues]
 [-refreshNodes]
 [-refreshUserToGroupsMappings]
 [-refreshSuperUserGroupsConfiguration]
 [-help [cmd]]
```

**Parameters**

The following command parameters are supported for `hadoop mradmin`:

| Parameter                                         | Description                                                                                               |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>-refreshServiceAcl</code>                   | Reload the service-level authorization policy file Job tracker will reload the authorization policy file. |
| <code>-refreshQueues</code>                       | Reload the queue acls and state JobTracker will reload the <code>mapred-queues.xml</code> file.           |
| <code>-refreshUserToGroupsMappings</code>         | Refresh user-to-groups mappings.                                                                          |
| <code>-refreshSuperUserGroupsConfiguration</code> | Refresh superuser proxy groups mappings.                                                                  |
| <code>-refreshNodes</code>                        | Refresh the hosts information at the job tracker.                                                         |
| <code>-help [cmd]</code>                          | Displays help for the given command or all commands if none is specified.                                 |

The following generic options are supported for `hadoop mradmin`:

| Generic Option                                                  | Description                                                                 |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------|
| <code>-conf &lt;configuration file&gt;</code>                   | Specify an application configuration file.                                  |
| <code>-D &lt;property=value&gt;</code>                          | Use value for given property.                                               |
| <code>-fs &lt;local filesystem URI&gt;</code>                   | Specify a filesystem.                                                       |
| <code>-jt &lt;local jobtracker:port&gt;</code>                  | Specify a job tracker.                                                      |
| <code>-files &lt;comma separated list of files&gt;</code>       | Specify comma separated files to be copied to the map reduce cluster.       |
| <code>-libjars &lt;comma separated list of jars&gt;</code>      | Specify comma separated jar files to include in the classpath.              |
| <code>-archives &lt;comma separated list of archives&gt;</code> | Specify comma separated archives to be unarchived on the computer machines. |

## hadoop pipes

The `hadoop pipes` command runs a pipes job.

 **Warning:** This command is deprecated.

Hadoop Pipes is the C++ interface to Hadoop Reduce. Hadoop Pipes uses sockets to enable tasktrackers to communicate processes running the C++ map or reduce functions.

### Syntax

```
hadoop [GENERIC OPTIONS] pipes
 [-output <path>]
 [-jar <jar file>]
 [-inputformat <class>]
 [-map <class>]
 [-partitioner <class>]
 [-reduce <class>]
 [-writer <class>]
 [-program <executable>]
 [-reduces <num>]
```

### Parameters

#### Command Options

The following command parameters are supported for `hadoop pipes`:

| Parameter                                | Description                        |
|------------------------------------------|------------------------------------|
| <code>-output &lt;path&gt;</code>        | Specify the output directory.      |
| <code>-jar &lt;jar file&gt;</code>       | Specify the jar filename.          |
| <code>-inputformat &lt;class&gt;</code>  | InputFormat class.                 |
| <code>-map &lt;class&gt;</code>          | Specify the Java Map class.        |
| <code>-partitioner &lt;class&gt;</code>  | Specify the Java Partitioner.      |
| <code>-reduce &lt;class&gt;</code>       | Specify the Java Reduce class.     |
| <code>-writer &lt;class&gt;</code>       | Specify the Java RecordWriter.     |
| <code>-program &lt;executable&gt;</code> | Specify the URI of the executable. |
| <code>-reduces &lt;num&gt;</code>        | Specify the number of reduces.     |

#### Generic Options

The following generic options are supported for the `hadoop pipes` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|filesystem URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see [Generic Options](#).

#### hadoop queue

The `hadoop queue` command displays job queue information.

 **Warning:** This command is deprecated.

## Syntax

```
hadoop [Generic Options] queue
 [-list] | [-info <job-queue-name> [-showJobs]] | [-showacIs]
```

## Parameters

### Command Options

The `hadoop queue` command supports the following command options:

| Parameter                                             | Description                                                                                                                                                                                                       |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-list</code>                                    | Gets list of job queues configured in the system. Along with scheduling information associated with the job queues.                                                                                               |
| <code>-info &lt;job-queue-name&gt; [-showJobs]</code> | Displays the job queue information and associated scheduling information of particular job queue. If <code>-showJobs</code> option is present, a list of jobs submitted to the particular job queue is displayed. |
| <code>-showacIs</code>                                | Displays the queue name and associated queue operations allowed for the current user. The list consists of only those queues to which the user has access.                                                        |

### Generic Options

The following generic options are supported for the `hadoop queue` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|filesystem URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see [Generic Options](#).

### hadoop version

The `hadoop version` command prints the hadoop software version.

## Syntax

```
hadoop version
```

## Output

```
$ hadoop version
Hadoop 2.7.6.100-eep-800
Subversion git@github.com:mapr/private-hadoop-common -r
80dc89ae5df3a2cd01089f192c5d8a886e4788c9
Compiled by root on 2021-10-08T11:26Z
Compiled with protoc 3.11.1
From source with checksum 124ac1b54c81145154c71d2be2a66fc
This command was run using /opt/mapr/hadoop/hadoop-2.7.6/share/hadoop/
common/hadoop-common-2.7.6.100-eep-800.jar
```

### hadoop conf

The `hadoop conf` command outputs the configuration information for this node to standard output.

## Syntax

```
hadoop [generic options] conf
```

## Examples

### Displaying the configured value of a specific parameter

```
[user@hostname ~]$ hadoop conf | grep mapreduce.map.memory.mb
<property><name>mapreduce.map.memory.mb</name><value>1024</
value><source>mapred-site.xml</source></property>
```

The above command returns 1024 as the configured value of the `mapreduce.map.memory.mb` parameter.

### Dumping a node's configuration to a text file

```
[user@hostname ~]$ hadoop conf | grep ... >nodeconfiguration.txt
```

The above command creates a text file named `nodeconfiguration.txt` that contains the node's configuration information.

The following information displays when you use the `tail` utility to examine the last few lines of the file:

```
[user@hostname ~]# tail nodeconfiguration.txt
 <property><name>yarn.app.mapreduce.am.resource.mb</
name><value>1536</value><source>mapred-default.xml</source></property>
 <property><name>mapreduce.framework.name</name><value>yarn</
value><source>mapred-default.xml</source></property>
 <property><name>mapreduce.job.reduce.slowstart.completedmaps</
name><value>1.00</value><source>mapred-default.xml</source></property>
 <property><name>yarn.resourcemanager.client.thread-count</
name><value>50</value><source>yarn-default.xml</source></property>

<property><name>mapreduce.cluster.temp.dir</name><value>${hadoop.tmp.dir}/
mapred/temp</value><source>mapred-default.xml</source></property>
 <property><name>yarn.resourcemanager.staging</name><value>/var/
mapr/cluster/yarn/rm/staging</value></property>
 <property><name>fs.mapr.working.dir</name><value>/user/
$USERNAME/</value></property>
 <property><name>mapreduce.jobhistory.intermediate-done-dir</
name><value>${yarn.app.mapreduce.am.staging-dir}/history/done_intermediate</
value><source>mapred-default.xml</source></property>
 <property><name>fs.s3a.attempts.maximum</name><value>10</
value><source>core-default.xml</source></property>

## API Documentation

HPE Ezmeral Data Fabric supports public APIs for filesystem, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Event Streams. These APIs are available for application-development purposes.

**Important:** Development using HPE Ezmeral Data Fabric non-public (private or internal) APIs is not supported.

Table

| Feature                                              | Language | Link to Location                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                |

## Other Docs

---

This section contains release-independent information, including: Installer documentation, Ecosystem release notes, interoperability matrices, security vulnerabilities, and links to other data-fabric version documentation.

## Products Covered in the HPE Ezmeral Data Fabric Documentation

---

This section lists the products covered in the HPE Ezmeral Data Fabric documentation portal and provides links to the related product documentation.

The HPE Ezmeral Data Fabric documentation portal provides information and instructions for the following HPE Ezmeral Data Fabric components and features:

### HPE Ezmeral Data Fabric File Store

#### File Store Documentation

Most of the file store conceptual and overview documentation is located in the [HPE Ezmeral Data Fabric File Store](#) on page 407 section of the documentation portal. Additional file store documentation, including installation and upgrade, configuration, and administration is located in the [6.2 Installation](#) on page 66, [6.2 Administration](#) on page 828, and [6.2 Development](#) on page 2641 sections of the documentation portal.

The following list provides some direct links to file store topics:

- [Distributed datastore for files](#) and [persistent storage for containers](#)

- [POSIX Client](#)
- [Platinum POSIX Client](#)
- [Container Client](#) including [PACC](#), [Flex Volume Plugin](#) and [CSI](#)
- [NFSv4](#) and [NFSv3](#)
- [Multiple file server instances per node](#)
- [Support for HDD and SSD](#)
- [HDFS API](#) and [HttpFS](#)
- [Quotas](#)
- [Snapshots](#)
- [Data Topologies](#)
- [Data Protection Replication](#)
- [Multi-site volume mirroring](#)
- [Data tiering \(Cold\)](#) to 3rd party external stores
- [Data tiering \(Warm\)](#) to erasure coding
- [Global Namespace](#)
- [Compression](#)
- [Unified Security](#) including authentication, authorization, encryption (wire and data-at-rest) and auditing
- [Policy-based security](#)
- [External KMIP Keystore](#)
- [HPE Ezmeral Data Fabric Management](#) using [CLI](#), [REST](#), and [GUI](#)
- [Rolling Upgrades](#)
- [HPE Ezmeral Data Fabric Monitoring](#)
- [HPE Ezmeral Data Fabric Installer](#)
- [Resiliency and self-healing](#)
- [Auto-balancing](#)
- [Disaster recovery](#) - See also [Mirror Volumes](#) on page 419.
- [Multitenancy on File System](#) on page 450

## HPE Ezmeral Data Fabric Document Database

### Document Database Documentation

Most of the document database conceptual and overview documentation is located in the [HPE Ezmeral Data Fabric Database](#) on page 458 section of the documentation portal. Additional document database

documentation, including installation and upgrade, configuration, and administration is located in the [6.2 Installation](#) on page 66, [6.2 Administration](#) on page 828, and [6.2 Development](#) on page 2641 sections of the documentation portal.

The following list provides some direct links to document database topics:

- [Column-Oriented Database](#) using [HBase API](#)
- [JSON document database](#) using [OJAI API](#)
- [Multi-master table replication](#)
- [Secondary indexes](#)
- [Multiple file server instances per node](#)
- [Change Data Capture \(CDC\)](#)
- [HPE Ezmeral Data Fabric DB Data Access Gateway](#)
- [Strong consistency](#) - See also [Mirroring and Replication](#) and [High Availability](#) on page 464.
- [Resiliency and self-healing](#) - See also [High Availability](#) on page 464.
- [Disaster recovery](#) - See also [Mirroring and Replication](#) and [High Availability](#) on page 464.
- [Automatic compactions](#)
- [Multitenancy](#)
- [Unified Security including authentication, authorization, encryption \(wire and data-at-rest\) and auditing](#)
- [Policy-based security](#)
- [HPE Ezmeral Data Fabric Administration](#)
- [HPE Ezmeral Data Fabric Monitoring](#)
- [HPE Ezmeral Data Fabric Installer](#)
- [Rolling upgrades](#)
- [Apache HBase](#)

## HPE Ezmeral Data Fabric Event Data Streams

### Event Data Streams Documentation

Most of the event data streams conceptual and overview documentation is located in the [HPE Ezmeral Data Fabric Event Streams](#) on page 590 section of the documentation portal. Additional event data streams documentation, including installation and upgrade, configuration, and administration is located in the [6.2 Installation](#) on page 66, [6.2 Administration](#) on page 828, and [6.2 Development](#) on page 2641 sections of the documentation portal..

The following list provides some direct links to event data streams topics:

- [Distributed publish-subscribe messaging infrastructure](#)
- [Support for Kafka API](#)
- [Kafka Connect](#)

- [Kafka REST Proxy](#)
- [KSQL](#)
- [Kafka Streams](#)
- [Kafka Schema Registry](#)
- [Multi-site Stream replication](#)
- [Automatic partition balancing](#)
- [Multi Tenancy](#)
- [Unified Security including authentication, authorization, encryption \(wire and data-at-rest\) and auditing](#)
- [HPE Ezmeral Data Fabric Administration](#)
- [HPE Ezmeral Data Fabric Monitoring](#)
- [HPE Ezmeral Data Fabric Installer](#)
- [Rolling upgrades](#)

## HPE Ezmeral Data Fabric Analytics with Hadoop

### Analytics with Hadoop Documentation

Most of the documentation related to analytics with Hadoop is located in the [Ecosystem Components](#) on page 3378 section of the documentation portal.

The following list provides some direct links to analytics with Hadoop topics:

- [Apache YARN](#)
- [Apache MapReduce v2](#)
- [Apache Hive](#)
- [Apache Pig](#)
- [Apache Sqoop](#)
- [Apache Flume](#)
- [Apache Oozie](#)
- [Apache Hue](#)
- [HPE Ezmeral Data Fabric DB OJAI Connector for Apache Hive](#)
- [S3 Gateway](#) on page 4186

## HPE Ezmeral Data Fabric Advanced Analytics with Spark

### Advanced Analytics with Spark Documentation

Most of the documentation related to analytics with Spark is located in the [Apache Spark](#) on page 4243 section of the documentation portal.

The following list provides some direct links to analytics with Spark topics:

- Apache [YARN](#)
- Apache [Spark](#)
- Apache [Spark SQL](#)
- Apache [Spark Streaming](#)
- [Apache Spark MLlib](#)
- [GraphX](#)
- [SparkR](#)
- Support for [Spark Standalone](#) and [Spark on YARN](#)
- [HPE Ezmeral Data Fabric DB OJAI Connector for Apache Spark](#)
- [HPE Ezmeral Data Fabric DB Binary Connector for Apache Spark](#)
- [HPE Ezmeral Data Fabric Streams Integration](#)
- [S3 Gateway](#) on page 4186

## HPE Ezmeral Data Fabric Interactive SQL Engine with Drill

### Drill Interactive SQL Engine Documentation

Most of the documentation related to the Drill interactive SQL engine is located in the [Apache Drill](#) on page 3401 section of the documentation portal. You may also want to refer to the Apache Drill documentation at <https://drill.apache.org/docs/>.

The following list provides some direct links to Drill topics in the documentation portal and on the [Apache Drill site](#):

- [Schema-less ANSI-compliant distributed SQL query engine](#)
- [Queries on File](#)
- [Queries on HPE Ezmeral Data Fabric Document Database tables and secondary indexes](#)
- [Queries on Hive tables and views](#) - See also [CREATE VIEW](#).
- [File formats \(Text,JSON,Parquet\)](#)
- [Multiple data type support](#)
- [Impersonation](#)
- Support for [Drill standalone](#) and [Drill-on-YARN](#)
- [Drill query and administration UI](#) - See also [Starting the Web UI](#).
- [JDBC/ODBC drivers](#)
- [Drill Explorer](#)
- [SQLLine](#) - See also [Configuring the Drill Shell](#).
- [REST API](#) - See also [REST API Introduction](#).

- [Drill Monitoring](#)
- [S3 Gateway](#) on page 4186- See also [S3 Storage Plugin](#).

## HPE Ezmeral Data Fabric Platform Bundle

### Platform Bundle Documentation

The following list provides some direct links to platform documentation topics:

- [HPE Ezmeral Data Fabric File Store](#)
- [HPE Ezmeral Data Fabric Analytics with Hadoop](#)
- [HPE Ezmeral Data Fabric Advanced Analytics with Spark](#)
- [HPE Ezmeral Data Fabric Interactive SQL Engine with Drill](#)
- [HPE Ezmeral Data Fabric Document Database](#)
- [HPE Ezmeral Data Fabric Event Data Streams](#)

## Installer

---

You must download and run the Installer setup script before you can start the Installer web interface or issue Installer Stanza commands.

The Installer web interface simplifies the installation of an HPE Ezmeral Data Fabric cluster. After taking you through the process of selecting services and configuring the cluster, the installer installs data-fabric software. You can use the Installer to install:

- New-feature releases, such as 6.1.0 and 6.2.0
- Maintenance releases, such as 6.0.1 and 6.1.1
- Ecosystem components, such as Spark, Hive, and HBase – or [other components](#) contained in a Ezmeral Ecosystem Pack (EEP)

Before you begin, review the [Installer Prerequisites and Guidelines](#) on page 5601, which describe user, node, and security requirements for using the Installer. For cluster-planning information, see [Planning the Cluster](#) on page 66.

### Watch a Video About Setting Up and Running the Installer

To view a demonstration of setting up and running the Installer, [click here](#).

### Steps for Setting Up and Running the Installer

To set up and run the installer, complete the following steps:

1. **Select a node from which to run the Installer.** The node from which you run the Installer does not need to be one of the nodes on which you plan to install the cluster.
2. **Download the `mapr-setup.sh` script.** Choose *one* of the following options:

- Download the setup script directly from [package.mapr.hpe.com](https://package.mapr.hpe.com) to the node that will run the Installer:

#### Release 6.0.0 and later

```
wget https://package.mapr.hpe.com/releases/installer/
mapr-setup.sh -P /tmp
```

**Release 5.2.2 and earlier** (for more information, see [Selecting an Installer Version to Use](#) on page 5607)

```
wget https://package.mapr.hpe.com/releases/installer-v1.11.0/
mapr-setup.sh -P /tmp
```

- Download to your local workstation, and copy to the node that will run the Installer:
  - a. On the [Download Page](#), click **Download**, and save the setup script to a location on your workstation.
  - b. Use a tool such as `SCP` to copy the file to the node that will run the Installer:

```
scp mapr-setup.sh user@server:/tmp
```

### 3. Change the file permissions so that you can run the file.

```
chmod +x /tmp/mapr-setup.sh
```

4. **Run the `mapr-setup.sh` script to configure the node to run the Installer.** Run the following command as the `root` user from the directory that contains the script. The script prompts you for some information. If you have not used this script before, consider reviewing [Using mapr-setup.sh](#) on page 5609 to be prepared.

```
/tmp/mapr-setup.sh
```

### 5. Start the Installer. Open the Installer URL:

```
https://<Installer Node hostname/IPaddress>:9443
```

You are prompted to log in as the cluster administrator user that you configured while running the `mapr-setup.sh` script.

### Other Tasks You Can Perform with the Installer

Once the initial installation completes, you can use the same Installer URL to upgrade the cluster, apply a patch, or add nodes and additional services:

| Use this option            | To                                                                                                                                 |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>Extend Cluster</i>      | Add a host to an existing cluster.                                                                                                 |
| <i>Incremental Install</i> | Add or upgrade services that are already installed on the cluster.                                                                 |
| <i>Maintenance Update</i>  | Update your cluster to a new patch version of core or apply a patch.                                                               |
| <i>Version Upgrade</i>     | Upgrade the cluster to a newer data-fabric release, apply a patch, and upgrade services that are already installed on the cluster. |

|                  |                                                                                 |
|------------------|---------------------------------------------------------------------------------|
| <i>Shutdown</i>  | Stop the data-fabric services on the cluster.                                   |
| <i>Uninstall</i> | Remove existing data-fabric software before proceeding with a new installation. |

**Note:** The Installer definitions are updated frequently. See [Updating the Installer](#) on page 5614 to get the latest ecosystem components and data-fabric software.

### HPE Privacy Statement

To learn how HPE uses, shares, transfers, and manages personal information, see the [HPE Privacy Statement](#).

## Getting Started with the Installer

This section describes things you need to do to start using the Installer.

### Installer Prerequisites and Guidelines

The node on which you run the installer and the nodes you plan to include in your cluster must meet certain user, connectivity, and security requirements.

### Installer Requirements

The node that runs the Installer must meet the following requirements:

#### Installer Node

Beginning with Installer 1.6, the node that runs the Installer does not need to be one of the nodes you plan to install the cluster on. Ensure that the default umask for the root user is set to 0022 on all nodes in the cluster. You can change the umask setting in the `/etc/profile` file, or in the `.cshrc` or `.login` file. The `root` user must have a 0022 umask because the cluster admin user requires access to all files and directories under the `/opt/mapr` directory, even those initially created by `root` services.

#### Package Dependencies

Depending on the operating system, the Installer requires the following packages. If these packages are not found, the Installer attempts to download them from Internet repositories:

| Ubuntu Nodes                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Red Hat / CentOS Nodes                                                                                                                                                                                                                                                                                                                                                                                                                                                               | SLES Nodes                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• ca-certificates</li> <li>• curl*</li> <li>• debianutils</li> <li>• dnsutils</li> <li>• iputils-arping</li> <li>• libnss3</li> <li>• libssl1.0.0</li> <li>• libsysfs2</li> <li>• netcat</li> <li>• nfs-common</li> <li>• ntp</li> <li>• ntpdate</li> <li>• openssl</li> <li>• python-dev</li> <li>• python-pycurl</li> <li>• sdparm</li> <li>• sudo</li> <li>• syslinux</li> <li>• sysstat</li> <li>• uuid-runtime</li> <li>• wget</li> </ul> | <ul style="list-style-type: none"> <li>• curl*</li> <li>• device-mapper</li> <li>• iputils</li> <li>• libsysfs</li> <li>• lvm2</li> <li>• nc</li> <li>• nfs-utils</li> <li>• ntp</li> <li>• nss</li> <li>• openssl</li> <li>• python-devel</li> <li>• sdparm</li> <li>• sudo</li> <li>• syslinux</li> <li>• sysstat</li> <li>• wget</li> <li>• which</li> <li>• yum-utils</li> <li>• compat-openssl10 (required only when running MapR 6.1.x on RHEL version 8 and above)</li> </ul> | <ul style="list-style-type: none"> <li>• ca-certificates</li> <li>• curl*</li> <li>• device-mapper</li> <li>• iputils</li> <li>• libopenssl1_0_0</li> <li>• sysfsutils</li> <li>• lvm2</li> <li>• mozilla-nss</li> <li>• nfs-client</li> <li>• ntp</li> <li>• sdparm</li> <li>• sudo</li> <li>• syslinux</li> <li>• sysstat</li> <li>• util-linux</li> <li>• wget</li> <li>• libfreebl3</li> </ul> |

\*The curl version must be greater than 7.51.0.

### Repository Connectivity

The Installer requires connectivity to valid repositories for the:

- Operating system
- Core
- Ezmeral Ecosystem Pack (EEP)

The Installer can connect to an Internet repository or to a preinstalled local repository, as described in [Using a Local, Shared Repository With the Installer](#) on page 5622. If the Installer dependencies and

packages are present, but there is no connectivity to an OS repository, the Installer fails with the following message:

```
ERROR: Unable to install dependencies
(installer). Ensure that a core
OS repo is enabled and retry
mapr-setup.sh
```

## Java

Installer 1.14 requires Java JDK 11 or an equivalent Java distribution. Before using Installer 1.14 on Ubuntu 16.04 nodes, you must manually install the JDK. If you are using Installer 1.14 on RHEL/CentOS or SLES, the Installer installs OpenJDK 11 for you.

For more information about the supported Java JDK versions, see the [JDK Support Matrix](#) on page 5800 and [Java](#) on page 121.

## SSH Access

The Installer must have SSH access to all nodes that you want to include in the cluster.

## Port Availability

Port 9443 or the non-default port that you configure using `mapr-setup.sh` must be accessible on the Installer node to all nodes that you want to include in the cluster.

## Files Extracted into /tmp Require Execute Privileges

Do not mount `/tmp` with the `noexec` option. The HPE Ezmeral Data Fabric extracts certain files into `/tmp` and must run them from `/tmp`. Some processes can fail if `noexec` is set for `/tmp` because some files extracted into `/tmp` require execute privileges. In addition, if you use the `java.io.tmpdir` variable to change the location of the temporary directory used by Java processes, then the newly specified temporary directory must not be mounted with the `noexec` option.

Perform the following steps to change the location of the temporary directory used by Java processes using `java.io.tmpdir` variable:

1. Create a custom `tmp` directory for `mapr` and set its permission similar to `/tmp`.

```
mkdir /opt/mapr/tmp
chmod 1777 /opt/mapr/tmp
```

2. Set the custom `tmp` directory as `java.io.tmpdir`.
  - a. For Java version 8 and previous, append the following command to `/opt/mapr/conf/env_override.sh` location.

```
export
_JAVA_OPTIONS="-Djava.io.tmpdir
=/opt/mapr/tmp"
```

- b. For Java version 9 and later, run the following command:

```
export
JDK_JAVA_OPTIONS="-Djava.io.tmp
dir=/opt/mapr/tmp"
```

3. Restart `mapr-warden` service on the node.

**Note:** You cannot hide the `Picked up _JAVA_OPTIONS: <...>` message due to Java sources implementation.

## Supported Web Browsers

Once the Installer is installed and configured, you can use the following web browsers to access the Installer web interface:

- Safari
- Firefox
- Chrome

## User Requirements

The installation process requires a valid cluster admin user to be present on all nodes in the cluster. The Installer can create a user (the `mapr` user) for you or use a user that you have created. If you choose to create a cluster admin user, make sure the following conditions are met:

- The user must have a home directory and a password.
- The user must be present on all nodes in the cluster.
- The numeric user and group IDs (`MAPR_UID` and `MAPR_GUID`) must be configured for the user, and these values must match on all nodes.
- The `mapr` user and `root` user must be configured to use `bash`. Other shells are not supported.

If the user is not a valid user, installation errors can result. For information about creating the user, see [Managing Users and Groups](#) on page 828.

If you choose to have the Installer create the user, the Installer runs the following command to add a local user to serve as the cluster admin user:

```
useradd -m -u $MAPR_UID -g $MAPR_GID -G $(stat -c '%G' /etc/shadow)
$MAPR_USER
```

In this command:

- `MAPR_USER` defaults to `mapr`.
- `MAPR_UID` defaults to 5000.
- `MAPR_GID` defaults to 5000.
- The home directory is typically `/home/mapr`.

The installer also adds the following to the `MAPR_USER .bashrc` file:

```
[[-f /opt/mapr/conf/env.sh]] && . /opt/mapr/conf/env.sh
```

## Node Requirements

Nodes that you want to include in the cluster must meet the following criteria:

### Enabling Package Repositories for SLES 15

Before using the Installer for a new data-fabric installation on SLES 15 SP2, run the following command on all nodes to enable the Python 2 package repository. You must also run the command on the Installer node if the Installer node is not part of the cluster and is running SLES 15 SP2 (or a later supported service pack):

```
SUSEConnect -p
sle-module-python2/15.<version>/x86_64
```

If you are developing applications on the cluster, run the following command on all nodes:

```
SUSEConnect -p
sle-module-development-tools/
15.<version>/x86_64
```

To view the available SLES modules and learn how to enable or disable them, use the `SUSEConnect -l` command.

### Fully Qualified Domain Names (FQDNs)

The nodes are expressed as fully-qualified domain names (FQDNs), as described in [Connectivity](#) on page 119. DO NOT specify hostnames as aliases or IP addresses.

### OS and Security Updates

Nodes are configured to accept operating system and security updates. They must also be patched with the latest security fixes. See your operating-system vendor documentation for details.

### Disk Space Requirements

Nodes meet the requirements listed in [Preparing Each Node](#). The Installer verifies the requirements prior to installation.

OS-partition, disk, and swap-space requirements are the same whether you install the cluster manually or by using the Installer. See [Minimum Disk Space](#) on page 118.

For data disks, Installer versions 1.12.0.0 and later require a minimum disk size that is equal to the physical memory on the node. If a data disk does not meet the minimum disk size requirement, a verification error is generated.

### Access to the Installer Node

Nodes have HTTPS access to the Installer node over port 9443.

### Proxy Server Requirements

If nodes in the cluster use an HTTP proxy server, the nodes must also meet the following requirements:

- The `no_proxy` environment variable must be set.

Nodes in the cluster need to be able to communicate without the use of a proxy. If the `https_proxy` and `http_proxy` environment variable is set for nodes in the cluster, you must also set the `no_proxy` environment variable for the cluster admin user and the `root` user on each node. Configure the `no_proxy` environment variable to the IP range of the nodes or to the sub-domain that contains the nodes.

In addition, you must follow this guideline from the [Python documentation](#): "The `no_proxy` environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port` appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`."

For cloud-based clusters (Amazon EC2, Google Compute Engine (GCE), and Microsoft Azure), you must include this entry in the no-proxy configuration:

```
169.254.169.254
```

- The global proxy for package repositories must be set.

The Installer creates repository files. However, the proxy setting is not configured for each repository. Therefore, configure global proxy settings on each node in the cluster.

- On CentOS/RedHat, set global proxy settings in `/etc/yum.conf`.
- On Ubuntu, set global proxy settings in `/etc/apt/apt.conf`.

## Security Requirements

Before installing or upgrading software using the Installer, make sure that you have reviewed the list of known vulnerabilities in [Security Vulnerabilities](#) on page 6767. If a vulnerability applies to your release, contact your support representative for a fix, and apply the fix immediately, if applicable.

## Cloud Requirements

When you run the Installer on nodes in the cloud, you must:

- **Verify that port 9443 is open.**

The Installer requires that this port is available.

- **Ensure that the Installer and service UI URLs should refer to an external URL and not an internal URL.**

For example, when you open the Installer URL, replace any internal hostname or IP address with its associated external address. For Amazon EC2 and Google Compute Engine (GCE) clusters, the Installer automatically translates internal addresses to external addresses.

- **On the Configure Nodes page of the Installer web interface, make sure that you do the following:**

- Define each node using a fully-qualified domain name (FQDN) and internal, resolvable hostnames, as described in [Connectivity](#) on page 119.
- For the remote authentication, use the same user ID and private key that you use to ssh into your cloud instances. This user must be `root` or a user with `sudo` permissions.

### Related concepts

[Installer Updates](#) on page 5684

Installer updates provide new features or bug fixes.

### Related tasks

[Checking the Installer Version](#) on page 5617

Some Installer features require you to use the latest version of the Installer. You can check the Installer version easily from within the user interface.

### Related reference

[Installer Support Matrix](#) on page 5802

This matrix shows the operating systems that are supported by the Installer.

### Selecting an Installer Version to Use

Beginning with the EEP 6.2.0 release, several Installer versions are available for use. The version that you use depends on your current core version and whether or not you need to upgrade using the Installer or Stanzas.

### Choosing an Installer Version

In general, you should always use the latest available Installer version. The latest Installer version provides access to the latest Ezmeral Ecosystem Packs (EEPs). To download the latest version, see [Installer Downloads](#) on page 5608 later on this page. For a list of recent Installer versions, see [Installer Updates](#) on page 5684.

However, the newer Installer versions do not support Release 5.x. You must use Installer 1.11.0.0 or 1.12.0.0 if your cluster is on a 5.x release. Installer 1.11.0.0 is the last version of the Installer to support installation for Release 5.x. Installer 1.12.0.0 is the last version of the installer to support upgrades from Release 5.2.x to Release 6.x.

If your cluster runs Release 5.2.x or a lower version of core, you must use Installer 1.11.0.0 to perform the following operations:

- New installs
- Incremental installs
- Patch installs
- Maintenance updates
- Extend-cluster operations

This table describes how to select the Installer version based on your current software and your upgrade plans:

| Core Version | Use This Installer Version                                                                                                                                                                                                                                                                                        |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5.1          | Use Installer 1.11.0.0 for all operations, including upgrades to Release 5.2.x. Note that you must upgrade to 5.2.x with EEP 3.0.1 or later if you eventually want to upgrade to Release 6.x. After upgrading to 5.2.x, if you need to upgrade to Release 6.x, update the Installer to 1.12.0.0 before upgrading. |

| Core Version  | Use This Installer Version                                                                                                                                                                                                        |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5.2.x         | Use Installer 1.11.0.0 until you need to upgrade to Release 6.x. To upgrade to Release 6.x using the Installer, your cluster must have Release 5.2.x with EEP 3.0.1 or later. Before upgrading, update the Installer to 1.12.0.0. |
| 6.x and later | Except for Ubuntu 16.04 clusters, you may use the latest Installer version for all operations. See the <a href="#">Special Considerations for Ubuntu 16.04 Clusters</a> on page 5608.                                             |

### Special Considerations for Ubuntu 16.04 Clusters

As indicated in the [Installer Support Matrix](#) on page 5802, Installer 1.17 and later are supported only on Ubuntu 18.04 and 20.04. If your cluster is installed on Ubuntu 16.04:

- The Installer version that you can use depends on whether or not the Installer node is part of the cluster where you plan to install data-fabric software:
  - If the Installer node is part of the cluster, and the cluster is running Ubuntu 16.04, you must use Installer 1.16.0.x to install the software. You cannot use Installer 1.17 or later unless you upgrade the cluster to Ubuntu 18.04 or 20.04.
  - If the Installer node is not part of the cluster, and the cluster is running Ubuntu 16.04, you can use the latest Installer version on a node that is running any supported version of Ubuntu, RHEL, or SLES to install core 6.1.0 or core 6.2.
- If you need to upgrade from core 6.1.x to core 6.2, you must first upgrade your operating system to Ubuntu 18.04 or 20.04 and then install Installer 1.17 or later to perform the core software upgrade.

### Installer Downloads

This table summarizes download information for the Installer:

| Installer Version  | Download Location                                            | The <code>mapr-setup.sh</code> script provided in this location installs . . . |
|--------------------|--------------------------------------------------------------|--------------------------------------------------------------------------------|
| Latest Installer   | <code>package.mapr.hpe.com/releases/installer/</code>        | The most current <a href="#">version</a> of the Installer                      |
| Installer 1.16.0.x | <code>package.mapr.hpe.com/releases/installer-v1.16</code>   | Installer 1.16.0.2                                                             |
| Installer 1.12.0.0 | <code>package.mapr.hpe.com/releases/installer-v1.12.0</code> | Installer 1.12.0.0                                                             |
| Installer 1.11.0.0 | <code>package.mapr.hpe.com/releases/installer-v1.11.0</code> | Installer 1.11.0.0                                                             |

### Downloading Older Versions of the Installer

By default, the `mapr-setup.sh` file provided in the `installer-v<version>/` directories in <http://package.mapr.com/releases/> installs the most current version of the Installer – and *not* the version for which the directory is named.

However, you can download older Installer versions by using the latest `mapr-setup.sh`:

1. Download the 1.17 or later version of `mapr-setup.sh`. See [Installer](#) on page 5599.

2. Add the following environmental variable to your current shell:

```
export MAPR_INSTALLER_REPO_DIR=installer-v<version>
```

The `export` command tells `mapr-setup.sh` to install the Installer package from the directory you specify. For example, the following command causes `mapr-setup.sh` to install the v1.11.0 Installer:

```
export MAPR_INSTALLER_REPO_DIR=installer-v1.11.0
```

3. Run `mapr-setup.sh` as described in [Installer](#) on page 5599 to install the Installer version you specified using the `export` command.

This page shows the EEPs that are supported for different core releases and the current lifecycle status for each EEP.

### Using `mapr-setup.sh`

This topic describes how you can use and run the Installer setup script.

Before you can run the Installer, you must run the `mapr-setup.sh` script to set up the installation environment on a node that may or may not be part of the cluster. Then, you can run the Installer to perform the installation.

To download and run the `mapr-setup.sh` script, see [Installer](#) on page 5599.

### `mapr-setup.sh`

The `mapr-setup.sh` script performs the following steps to prepare the node to run the Installer:

1. Verifies and installs the operating system dependencies and Java requirements on the current node.
2. Checks for Internet connectivity to the remote repository.
  - If access to <https://package.mapr.hpe.com/> is not available, the script prompts for the archive tarballs. Provide the full paths of these tarballs in a space-delimited list.
3. Asks for the hostname and port that cluster nodes can use to connect to the Installer node.
4. Asks for the cluster admin user account and creates the account if it does not exist. This account must exist or be created on each node in the cluster. (The cluster admin is the cluster administrator.)

## 5. Sets up a custom yum or apt repository.

- If no archive file is provided, the script configures access to the <https://package.mapr.hpe.com/> repository. For example, on RedHat / CentOS, the script creates the following remote repository: `/etc/yum.repos.d/mapr.installer.repo`
- If archive files are provided, the script sets up a local repository.

## 6. Starts the Installer.

### Syntax

```
/opt/mapr/installer/bin/mapr-setup.sh
[docker client]
[docker installer]
[-a <full_path_to_archive_file(s)>]
[install]
[reload]
[remove]
[update]
[-h]
[-i <full_path_to_installer_package>]
[-n]
[-p <hostname:port>]
[-r <repository_URL>]
[-y]
```

### Options

In general, you should run the `mapr-setup.sh` script without using any additional options. Consider using the following options only if you have a known Internet connectivity issue, your Installer packages are not located in the default repository, or you need help with the installation process.

| Option                        | Description                                                                                                                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>docker client</code>    | Use this option to create a PACC image. For more information, see <a href="#">Creating a PACC Image Using mapr-setup.sh</a> on page 361.                                                                                                           |
| <code>docker installer</code> | Use this option to create a Installer container.                                                                                                                                                                                                   |
| <code>install</code>          | Use this option to install the Installer and definition files. If you don't specify an option for <code>mapr-setup.sh</code> , the <code>install</code> option is invoked by default.<br><br><b>Example:</b><br><pre>./mapr-setup.sh install</pre> |
| <code>reload</code>           | Use this option to reinstall the Installer and definition files. This option is helpful in debugging. No prompt is returned when you use this option.<br><br><b>Example:</b><br><pre>./mapr-setup.sh reload</pre>                                  |
| <code>remove</code>           | Use this option to remove the Installer and definition files. This option does not remove the <code>mapr-setup.sh</code> script.<br><br><b>Example:</b><br><pre>./mapr-setup.sh remove</pre>                                                       |

| Option          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| update          | <p>Use this option to update the installer packages. The setup script checks <a href="https://package.mapr.hpe.com/">https://package.mapr.hpe.com/</a> for new packages and installs the packages if they are available.</p> <p><b>Example:</b></p> <pre>./mapr-setup.sh update</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| -a   --archives | <p>Use this option to bypass the Internet connectivity check and directly create a local repository. Specify a space-delimited list of the full paths to the following archive files (the order of the files is important) as an argument to the option:</p> <ul style="list-style-type: none"> <li>• Installer archive</li> <li>• Ezmeral Ecosystem Pack (EEP) archive</li> <li>• MapR archive for the current release</li> </ul> <p>For more information, see <a href="#">Using a Local, Shared Repository With the Installer</a> on page 5622.</p> <p> <b>Note:</b> Use this option when the Installer node does not have access to the Internet or is behind a restricted VPN or firewall.</p> <p><b>Example for Releases 5.2 and later:</b></p> <pre>./mapr-setup.sh -a mapr-installer-v1.5.201705041557.deb.tgz mapr-mep-v3.0.0.201704051422.deb.tgz mapr-v5.2.1GA.deb.tgz</pre> <p><b>Example for Releases 5.0 and 5.1:</b></p> <pre>./mapr-setup.sh -a mapr-5.0-5.1.201705082100.deb.tar.gz</pre> <p>For Releases 5.0 and 5.1, you only need to provide the core archive file.</p> |
| -h   --help     | <p>Use this option to display the command-line help for the Installer.</p> <p> <b>Note:</b> If you use this option with other options, the Installer will ignore all options except for -h.</p> <p><b>Example:</b></p> <pre>./mapr-setup.sh -h</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -i   --install  | <p>Use this option to override the Installer packages stored in the remote or local repository. This option take a space-delimited list of the two local packages needed to install the Installer (the order of the files is not important):</p> <ul style="list-style-type: none"> <li>• Installer package</li> <li>• Installer definitions package</li> </ul> <p><b>Example:</b></p> <pre>./mapr-setup.sh -i mapr-installer-definitions_1.5.201705021610_all.deb mapr-installer_1.5.201705021610_all.deb</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
