IDENTIFIED BY 'secret' WITH GRANT OPTION;
mysql> flush privileges;
```

4. Optionally, verify the connectivity to the MySQL server running on `node3` from `node1` and `node2`. For example, run the following commands:

- On `node1`:

```
mysql -h node3 -uroot -psecret
```

- On `node2`:

```
mysql -h node3 -uroot -psecret
```

5. Add all Metastore instances to `hive.metastore.uris` on all nodes with the Hive instance:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://192.168.33.11:9083,thrift://
192.168.33.12:9083,thrift://192.168.33.13:9083 </value>
</property>
```

6. Restart Hive Metastore services on all nodes where Hive Metastore service is installed and then all `HiveServer2` instances.

```
maprcli node services -name hivemeta -action restart -nodes
<comma-separated list of Hive Metastore nodes>
```

7. Restart all HiveServer2 instances.

```
maprcli node services -name hs2 -action restart -nodes <comma-separated list of HiveServer2 nodes>
```

Check the status of Hive Metastore on the Control System. Following is a sample view of the Control System displaying the status of Hive Metastore.

All (23)

Service	Running Nodes	Standby Nodes	Failed Nodes	Stopped Nodes	
MEP					
Data Access Gateway	2	-	0	0	[▶] [■] [↺]
HBase Rest Server	3	-	0	0	[▶] [■] [↺]
HBase Thrift Server	1	0	0	0	[▶] [■] [↺]
HBase Master	2	-	0	0	[▶] [■] [↺]
HBase Region Server	3	-	0	0	[▶] [■] [↺]
s3server	3	-	0	0	[▶] [■] [↺]
TezUI	1	-	0	0	[▶] [■] [↺]
Timeline Server	1	0	0	0	[▶] [■] [↺]
Hive	-	-	-	-	
• Hive Server2	1	0	0	0	[▶] [■] [↺]
• Hive Metastore	1	2	0	0	[▶] [■] [↺]
• WebHCat	1	0	0	0	[▶] [■] [↺]

Note: A tooltip for the Hive Metastore row shows "Nodes Running" with a link to "node5.cluster.com".

Hive Features in HPE Ezmeral Data Fabric

Describes HPE Ezmeral Data Fabric-specific features in Hive.

Removing Temporary Hive Files

Starting from EEP 8.1.0, EEP 7.1.2, and EEP 6.3.6, to remove the temporary Hive files created during the Hive session, set the value of `hive.scratchdir.lock` property to `true` on `hive-site.xml` file.

```
<property>
  <name>hive.scratchdir.lock</name>
  <value>>true</value>
</property>
```

For the previous EEP versions, manually remove the temporary Hive files that are not used by the active Hive sessions.

You have two different situations:

- If you have configured the HiveServer2 in a node, set `hive.scratchdir.lock` property on the `hive-site.xml` file to automatically remove the temporary Hive files.
- If you have not configured the HiveServer2 in a node, set the `hive.scratchdir.lock` property and run the following command to remove the temporary Hive files.

```
hive --service cleardanglingscratchdir
```

Symbolic Link Support in Hive

Starting from EEP 7.1.0, all [hadoop fs](#) commands support operations on symlinks (symbolic links). Hive supports symlinks in EEP 8.0.0 onwards. You can create symlinks through the command line interface or file system API (MapRFileSystem.java).

Symlink creation via CLI has the following requirements:

- [NFS installed](#)
- [NFS mounted](#) (mount `hadoop fs` to the local file system)

Creating Symlinks

The following examples demonstrate how to create symbolic links via CLI and MapRFileSystem API:

- Create a *relative* symlink via CLI:

```
ln -rs /mountPoint/path/to/file /
mountPoint/path/to/symlink
```

- Create an *absolute* symlink via CLI:

```
ln -s /mountPoint/path/to/file /
mountPoint/path/to/symlink
```

- Create a symlink via MapRFileSystem API:

```
MapRFileSystem maprFS
= MapRFileSystem.get(new
Configuration());
maprFS.createSymlink(pathToTarget,
pathToLink, createParentFlag);
```

Using Symlinks for Hive Operations

Once a symlink is created, you can use the symlink for Hive operations, such as table location and data file, as demonstrated in the following steps:

1. Create a table directory:

```
mkdir /mapr/my.cluster.com/user/
hive/warehouse/ext_tbl_symlink
```

2. Create a symlink from a data source to a table location:

```
ln -s /mapr/my.cluster.com/user/
mapr/source_files/data.txt /mapr/
my.cluster.com/user/hive/warehouse/
ext_tbl_mh120/data_link.txt
```

3. Create an external Hive table in the `ext_tbl_symlink` directory (created in step 1):

```
CREATE EXTERNAL TABLE
file_link_table (...) ROW FORMAT
DELIMITED FIELDS TERMINATED BY ","
STORED AS TEXTFILE LOCATION '/user/
hive/warehouse/ext_tbl_symlink';
```

The Hive table has a symbolically linked text file as the data source. Data can be processed as if it is a regular data file.

Hive 2.3 API Changes

This topic describes the public API changes that occurred between Hive 2.1 EEP 5.0.0 and Hive 2.3 EEP 6.0.0.

For more information, see the [Hive 2.1.1-1803 \(EEP 4.1.1 and EEP 5.0.0\) Release Notes](#) on page 7029 and [Hive 2.3.3-1808 \(EEP 6.0.0\) Release Notes](#) on page 7002.

JDBC classes API changes

This section contains changes made to classes related to the JDBC API in Hive.

Table

Method	Description
<code>List<String> parseInitFile(String initFile)</code>	Parses initial SQL file skipping comments that starts with # or --.

Table

Method	Description
<code>void setInPlaceUpdateStream(InPlaceUpdate stream)</code>	Only used by the beeline client to set the stream on which in place progress updates are to be shown.

Table

Method	Description
JdbcConnectionParams parseURL(String uri)	<p>Parse JDBC connection URL. The new format of the URL is:</p> <pre>jdbc:hive2://:,:/dbName;sess_var_list? hive_conf_list#hive_var_list</pre> <p>where the optional <code>sess</code>, <code>conf</code>, and <code>var</code> lists are semicolon separated = pairs. For utilizing dynamic service discovery with HiveServer2, multiple comma-separated host:port pairs can be specified as shown above. The JDBC driver resolves the list of URIs and picks a specific server instance to connect to. Currently, dynamic service discovery using ZooKeeper is supported, in which case the host:port pairs represent a ZooKeeper ensemble. As before, if the host/port is not specified, the driver runs an embedded Hive:</p> <ul style="list-style-type: none"> <code>jdbc:hive2://ubuntu:11000/db2?hive.cli.conf.printhead=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID</code> <code>jdbc:hive2://?hive.cli.conf.printhead=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID</code> <code>jdbc:hive2://ubuntu:11000/db2;user=foo;password=bar</code> <p>Connect to <code>http://server:10001/hs2</code>, with specified basicAuth credentials and initial database:</p> <pre>jdbc:hive2://server:10001/ db;user=foo;password=bar? hive.server2.transport.mode= http;hive.server2.thrift.http.path=hs2</pre>

Security-related API changes

The following properties are removed from the default `hive-site.xml` configuration on a secured cluster:

Table

Property	Value
<code>hive.server2.webui.keystore.path</code>	<code>/opt/mapr/conf/ssl_keystore.</code>
<code>hive.server2.webui.keystore.password</code>	Default keystore password.

The following property is added to the default `hive-site.xml` configuration on a secured cluster:

Table

Method	Description
<code>hive.server2.use.SSL true</code>	<code>true</code>

Since the HiveServer2 server is configured to use SSL encryption by default starting from Hive-2.3 EEP-6.0.0, add `ssl=true;` to a JDBC connection string when PAM or MAPR-SASL authentication is used.

For example:

Old JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;
```

New JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;ssl=true;
```

NOTE: All API functionality changes are compatible with previous versions.

Hive 2.1 API

This section contains the following:

New Classes in Hive 2.1

Hive 2.1 includes the following new classes:

Class	Description
org.apache.hadoop.hive.common. DiskRangeInfo	Contains disk range information including disk ranges and total length.
org.apache.hadoop.hive.common. JvmPauseMonitor	This is based on the <code>JvmPauseMonitor</code> from Hadoop.
org.apache.hadoop.hive.common. StringableMap	A utility class that can convert a <code>HashMap</code> of Properties into a colon separated string, and can take the same format of string and convert it to a <code>HashMap</code> of Properties.
org.apache.hadoop.hive.common. ValidCompactorTxnList	An implementation of <code>org.apache.hadoop.hive.common.ValidTxnList</code> for use by the compactor.
org.apache.hadoop.hive.common.io. .DiskRange	The sections of a file.
org.apache.hadoop.hive.common.io. DiskRangeList	Alternative for Java linked list iterator interface to support concurrent modifications of the same list by multiple iterators.
org.apache.hadoop.hive.common.jsonexplain.tez. Printer	Creation of output string to show JSON plan.
org.apache.hadoop.hive.common.jsonexplain.tez. TezJsonParserUtils	JsonParser for Tez that prints a <code>JSONObject</code> into <code>OutputStream</code> .

Class	Description
org.apache.hadoop.hive.common.metrics. LegacyMetrics	The Metrics Subsystem allows exposure of a number of named parameters/counters via JMX, is intended to be used as a static subsystem, and has a couple of primary ways in which it can be used: <ul style="list-style-type: none"> Using the set and get methods to set and get named parameters. Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set. Using the startScope and endScope methods to start and end named "scopes" that record the number of times they have been instantiated and amount of time (in milliseconds) spent inside the scopes.
org.apache.hadoop.hive.common.type. RandomTypeUtil	Creates random data of different object types.
org.apache.hadoop.hive.conf. VariableSubstitution	Substitution of environment variables.
org.apache.hadoop.hive.contrib.genericudf.example. GenericUDFAdd10	Initializes the GenericUDF (once per instance), evaluates the GenericUDF with the arguments, and gets the string to display.
org.apache.hadoop.hive.io. HdfsUtils	Utils to resolve file properties in MAPR filesystem.
org.apache.hadoop.hive.metastore. AcidEventListener	It handles cleanup of dropped partition/table/database in ACID related metastore tables.
org.apache.hadoop.hive.metastore. FileMetadataHandler	The base implementation of a file metadata handler for a specific file type.
org.apache.hadoop.hive.metastore. FileMetadataManager	Handle storage functions of metadata.
org.apache.hadoop.hive.metastore. HMSMetricsListener	Report metrics of metadata added and deleted by this Hive Metastore.
org.apache.hadoop.hive.metastore. Metastore	Class to arrange work with Metastore.
org.apache.hadoop.hive.metastore. PartFilterExprUtil	Utility functions for working with partition filter expressions.
org.apache.hadoop.hive.metastore.api. AbortTxnsRequest	Class for handling transactions request.
org.apache.hadoop.hive.metastore.api. AddForeignKeyRequest	Class for handling foreign key request.
org.apache.hadoop.hive.metastore.api. AddPrimaryKeyRequest	Class for handling primary key request.
org.apache.hadoop.hive.metastore.api. CacheFileMetadataRequest	Class for caching metadata requests.
org.apache.hadoop.hive.metastore.api. CacheFileMetadataResult	Class for caching metadata results.
org.apache.hadoop.hive.metastore.api. ClearFileMetadataResult	Class for clearing metadata results.
org.apache.hadoop.hive.metastore.api. DropConstraintRequest	Class for dropping constraint requests.
org.apache.hadoop.hive.metastore.api. ForeignKeysRequest	Class for handling foreign key requests.

Class	Description
org.apache.hadoop.hive.metastore.api. ForeignKeysResponse	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api. GetAllFunctionsResponse	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api. GetFileMetadataByExprRequest	Class for getting metadata from expression response.
org.apache.hadoop.hive.metastore.api. GetFileMetadataByExprResult	Class for getting metadata from expression result.
org.apache.hadoop.hive.metastore.api. MetadataPpdResult	Class for describing metadata rpd result.
org.apache.hadoop.hive.metastore.api. PrimaryKeysRequest	Class for describing primary key result.
org.apache.hadoop.hive.metastore.api. PrimaryKeysResponse	Class for describing primary key response.
org.apache.hadoop.hive.metastore.api. PutFileMetadataRequest	Class for output metadata request to file.
org.apache.hadoop.hive.metastore.api. PutFileMetadataResult	Class for output metadata result to file.
org.apache.hadoop.hive.metastore.api. SQLForeignKey	Class for describing SQL foreign key.
org.apache.hadoop.hive.metastore.api. SQLPrimaryKey	Class for describing SQL primary key.
org.apache.hadoop.hive.metastore.api. TableMeta	Class for describing table metadata.
org.apache.hadoop.hive.metastore.model. MConstraint	Model of constraints stored in metastore.
org.apache.hadoop.hive.metastore.txn. TxnUtils	Class for handling transactions.
org.apache.hadoop.hive.ql. CompilationOpContext	Contains the operator sequence ID and a subset of compilation context that is passed to operators to get rid of some globals.
org.apache.hadoop.hive.ql. QueryDisplay	Contains limited query information to save for WebUI. The class is synchronized, as WebUI may access information about a running query.
org.apache.hadoop.hive.ql. QueryState	The class to store query level info such as queryId.
org.apache.hadoop.hive.ql.exec. AbstractMapOperator	Abstract Map operator.
org.apache.hadoop.hive.ql.exec. GlobalWorkMapFactory	Get job that has been executed on cluster as a map value.
org.apache.hadoop.hive.ql.exec. ObjectCacheWrapper	Wrapping class for ObjectCache class.
org.apache.hadoop.hive.ql.exec. SerializationUtilities	Utilities related to serialization and deserialization.
org.apache.hadoop.hive.ql.exec. UDFClassLoader	UDFClassLoader is used to dynamically register udf (and related) jars. This was introduced to fix HIVE-11878. Each session will have its own instance of UDFClassLoader to support HiveServer2, which can contain multiple active sessions.
org.apache.hadoop.hive.ql.exec.spark. CacheTran	Class for making cache persistent.
org.apache.hadoop.hive.ql.exec.spark. SmallTableCache	Class for cache cleaning if new query is present.
org.apache.hadoop.hive.ql.exec.spark. SparkDynamicPartitionPruner	The spark version of DynamicPartitionPruner.

Class	Description
org.apache.hadoop.hive.ql.exec.spark.status.impl. SparkJobUtils	Utilities for spark job.
org.apache.hadoop.hive.ql.exec.tez. ColumnarSplitSizeEstimator	Split size estimator for columnar file formats.
org.apache.hadoop.hive.ql.exec.tez. HostAffinitySplitLocationProvider	This maps a split (path + offset) to an index based on the number of locations provided.
org.apache.hadoop.hive.ql.exec.tez. InPlaceUpdates	Class responsible for inplace updates.
org.apache.hadoop.hive.ql.exec.tez. KeyValuesFromKeyValue	Provides a key/values (note the plural values) interface out of a KeyValueReader, needed by ReduceRecordSource when reading input from a key/value source.
org.apache.hadoop.hive.ql.exec.tez. KeyValuesFromKeyValues	Provides a key/values interface out of a KeyValuesReader for use by ReduceRecordSource.
org.apache.hadoop.hive.ql.exec.tez. LlapObjectCache	Llap implementation for the shared object cache.
org.apache.hadoop.hive.ql.exec.tez. Utils	Utilities for running tez jobs.
org.apache.hadoop.hive.ql.exec.vector. IntervalDayTimeColumnVector	This class represents a nullable interval day time column vector capable of handling a wide range of interval day time values.
org.apache.hadoop.hive.ql.exec.vector. ListColumnVector	The representation of a vectorized column of list objects.
org.apache.hadoop.hive.ql.exec.vector. MapColumnVector	The representation of a vectorized column of map objects.
org.apache.hadoop.hive.ql.exec.vector. MultiValuedColumnVector	The representation of a vectorized column of multi-valued objects, such as lists and maps.
org.apache.hadoop.hive.ql.exec.vector. StructColumnVector	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive.ql.exec.vector. TimestampColumnVector	This class represents a nullable timestamp column vector capable of handling a wide range of timestamp values.
org.apache.hadoop.hive.ql.exec.vector. UnionColumnVector	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive.ql.exec.vector. VectorSparkHashTableSinkOperator	Vectorized version of SparkHashTableSinkOperator. It delegates all the work to super class Copied from VectorFileSinkOperator.
org.apache.hadoop.hive.ql.exec.vector. VectorSparkPartitionPruningSinkOperator	Vectorized version for SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive.ql.exec.vector.expressions. BRoundWithNumDigitsDoubleToDouble	Banking rounding implementation.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastDoubleToTimestamp	Cast double type to timestamp type.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastLongToTimestamp	Cast long type to timestamp type.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastMillisecondsLongToTimestamp	Cast milliseconds long type to timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastStringGroupToString	Cast string group type to string type.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToBoolean	Cast timestamp type to boolean.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToDate	Cast timestamp type to decimal type.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToDouble	Cast timestamp type to double type.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToLong	Cast timestamp type to long type.
org.apache.hadoop.hive.ql.exec.vector.expressions. DateColSubtractDateColumn	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions. DateColSubtractDateScalar	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions. DateScalarSubtractDateColumn	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions. FilterStructColumnInList	Evaluates an IN filter on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions. FilterTimestampColumnInList	Evaluates IN filter on a batch for a vector of timestamps.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncBRoundWithNumDigitsDecimalToDecimal	Banking rounding for decimal digits.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncDecimalToTimestamp	This is a superclass for unary decimal functions and expressions returning timestamps that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncTimestampToDecimal	This is a superclass for unary timestamp functions and expressions returning decimals that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncTimestampToLong	This is a superclass for unary timestamp functions and expressions returning long that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprDoubleColumnDoubleColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeScalarColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeScalarScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprLongColumnLongColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnColumnBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnScalarBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarColumnBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarScalarBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColEqualLongColumn	If equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColEqualLongScalar	If equal long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterEqualLongColumn	If greater or equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterEqualLongScalar	If greater or equal long column and long scalar.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterLongColumn	If greater two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterLongScalar	If greater long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessEqualLongColumn	If less equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessEqualLongScalar	If less equal long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessLongColumn	If less two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessLongScalar	If less long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColNotEqualLongColumn	If not equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColNotEqualLongScalar	If not equal long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarEqualLongColumn	If equal long scalar and long column.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarGreaterEqualLongColumn	If greater equal long scalar and long column as vector.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarGreaterLongColumn	If greater long scalar and long column as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarLessEqualLongColumn	If less equal long scalar and long column as vector.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarLessLongColumn	If less long scalar and long column as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarNotEqualLongColumn	If not equal long scalar and long column as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.SelectStringColLikeStringScalar	Select like statement for string column and string scalar.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions. StructColumnInList	Evaluates an IN boolean expression (not a filter) on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions. TimestampColumnInList	Returns a boolean value indicating if a column is IN a list of constants.
org.apache.hadoop.hive.ql.exec.vector.expressions. TimestampToStringUnaryUDF	This is a superclass for unary long functions returning strings that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDateTimestamp	Vectorized version of TO_DATE(timestamp).
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDayOfMonthDate	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDayOfMonthTimestamp	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFHourDate	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFHourTimestamp	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMinuteDate	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMinuteTimestamp	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMonthDate	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMonthTimestamp	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFSecondDate	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFSecondTimestamp	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFTimestampFieldDate	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFTimestampFieldTimestamp	Abstract class to return various fields from a Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFUnixTimeStampDate	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFUnixTimeStampTimestamp	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFWeekOfYearDate	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFWeekOfYearTimestamp	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFYearDate	Expression to get year as a long.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFYearTimestamp	Expression to get year as a long.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. VectorUDAFVgTimestamp	Generated from template VectorUDAFVg.txt.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. VectorUDAFStdPopTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. VectorUDAFStdSampTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. VectorUDAFVarPopTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. VectorUDAFVarSampTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.hooks. LineageLogger	Implementation of a post execute hook that logs lineage info to a log file.
org.apache.hadoop.hive.ql.hooks. PostExecOrcFileDump	Post execution hook to print orc file dump for files that will be read by fetch task.
org.apache.hadoop.hive.ql.hooks. PostExecTezSummaryPrinter	Post execution hook to print hive tez counters to console error stream.
org.apache.hadoop.hive.ql.io. HdfsUtils	Utilities for hadoop fs.
org.apache.hadoop.hive.ql.io. IOContextMap	Uses the global static map of IOContext-s inside IOContext, uses threadlocal for Spark, and creates inheritable threadlocal with attemptId (only set in LLAP), which will propagate to all the Tez threads.
org.apache.hadoop.hive.ql.io. NullScanFileSystem	Filesystem that does not allow Hive to read files for nullscans.
org.apache.hadoop.hive.ql.io. ProxyLocalFileSystem	This class is to workaround existing issues on LocalFileSystem.
org.apache.hadoop.hive.ql.io. SyntheticFileId	Create synthetic ID for file.
org.apache.hadoop.hive.ql.io.orc. ExternalCache	Metastore-based footer cache storing serialized footers.
org.apache.hadoop.hive.ql.io.orc. MetastoreExternalCachesByConf	An implementation of external cache and factory based on metastore.
org.apache.hadoop.hive.ql.io.orc. OrcFileFormatProxy	File format proxy for ORC.
org.apache.hadoop.hive.ql.io.orc. RecordReaderImpl	Implementation of record reader.
org.apache.hadoop.hive.ql.io.parquet.read. ParquetFilterPredicateConverter	Translate the search argument to the filter predicate parquet uses.
org.apache.hadoop.hive.ql.io.sarg. ConvertAstToSearchArg	Converting asterisk and use it as a search argument.
org.apache.hadoop.hive.ql.io.sarg. SearchArgumentImpl	The implementation of SearchArguments.
org.apache.hadoop.hive.ql.lib. PreOrderOnceWalker	This class takes list of starting nodes and walks them in pre-order.
org.apache.hadoop.hive.ql.log. HiveEventCounter	A log4J2 appender that simply counts logging events in four levels: fatal, error, warn, and info.
org.apache.hadoop.hive.ql.log. NoDeleteRollingFileAppender	Instantiate a RollingFileAppender and open the file designated by filename. The opened filename will become the output destination for this appender.
org.apache.hadoop.hive.ql.log. NullAppender	A NullAppender that never outputs a message to any device.

Class	Description
org.apache.hadoop.hive.ql.log.PidFilePatternConverter	FilePattern converter that converts %pid pattern to @ information obtained at runtime.
org.apache.hadoop.hive.ql.metadata.ForeignKeyInfo	ForeignKeyInfo is a metadata structure containing the foreign keys associated with a table.
org.apache.hadoop.hive.ql.metadata.PrimaryKeyInfo	PrimaryKeyInfo is a metadata structure containing the primary key associated with a table.
org.apache.hadoop.hive.ql.metadata.TableIterable	Gets Table objects for a table list.
org.apache.hadoop.hive.ql.optimizer.OperatorComparatorFactory	Comparator for table operators.
org.apache.hadoop.hive.ql.optimizer.PartitionColumnsSelector	Takes a Filter expression, and if its predicate contains an IN operator whose children are constant structs or structs containing constant fields, it will try to generate predicate with IN clauses containing only partition columns.
org.apache.hadoop.hive.ql.optimizer.PointLookupOptimizer	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, it will try to generate an IN clause (which is more efficient).
org.apache.hadoop.hive.ql.optimizer.RedundantDynamicPruningConditionsRemoval	Takes a Filter operator on top of a TableScan and removes dynamic pruning conditions if static partition pruning has been triggered already.
org.apache.hadoop.hive.ql.optimizer.SparkRemoveDynamicPruningBySize	Disables pruning if the number of keys for dynamic pruning is too large.
org.apache.hadoop.hive.ql.optimizer.calcite.HivePlannerContext	Creating context for Hive Planner.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelBuilder	Builder for relational expressions in Hive.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelFactories	Factory class for creating relational operators for queries.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRegistryExecutorImpl	Hive registry executor implementation.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRegistryUtil	Utilities for hive registry executor.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveBetween	Operand type-inference strategy where an unknown operand type is derived from the first operand with a known type, but the first operand is a boolean.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveIn	Create in clause instance for hive queries.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveMultiJoin	A HiveMultiJoin represents a succession of binary joins.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit	Sorting limit in hive queries.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateJoinTransposeRule	Planner rule that pushes an <code>org.apache.calcite.rel.core.Aggregate</code> past a <code>org.apache.calcite.rel.core.Join</code> .
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateProjectMergeRule	Planner rule that recognizes a <code>HiveAggregate</code> on top of a <code>HiveProject</code> and if possible, aggregates through the project or removes the project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregatePullUpConstantsRule	Rule for pull up constants aggregation.

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterAggregateTransposeRule	Transpose rule for filter aggregation.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterProjectTSTransposeRule	Transpose rule for filtering project TST.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterSortTransposeRule	Transpose rule for filtering sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinProjectTransposeRule	Transpose rule for join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HivePointLookupOptimizerRule	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, tries to generate an IN clause (which is more efficient).
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectFilterPullUpConstantsRule	Planner rule that infers constant expressions from Filter into a Project operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectSortTransposeRule	Transpose rule for project sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveReduceExpressionsRule	Collection of planner rules that apply various simplifying transformations on RexNode trees.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveReduceExpressionsWithStatsRule	This rule simplifies the condition in Filter operators using the column statistics (if available).
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveRelColumnsAlignment	Infers the order in Aggregate columns and the order of conjuncts in a Join condition that might be more beneficial to avoid additional sort stages.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortJoinReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveJoin.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortLimitPullUpConstantsRule	Planner rule that pulls up constant keys through a SortLimit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortMergeRule	This rule will merge two HiveSortLimit operators.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortProjectTransposeRule	Transpose rule for sort project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortRemoveRule	Planner rule that removes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortUnionReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveUnion.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveUnionPullUpConstantsRule	Planner rule that pulls up constants through a Union operator.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdPredicates	Infers predicates for a project.
org.apache.hadoop.hive.ql.optimizer.physical.LlapDecider	LlapDecider takes care of tagging certain vertices in the execution graph as "llap", which in turn causes them to be submitted to an llap daemon instead of a regular yarn container.

Class	Description
org.apache.hadoop.hive.ql.optimizer.physical.MemoryDecider	MemoryDecider is a simple physical optimizer that adjusts the memory layout of tez tasks.
org.apache.hadoop.hive.ql.optimizer.physical.SerializeFilter	SerializeFilter is a simple physical optimizer that serializes all filter expressions in Tablescan Operators.
org.apache.hadoop.hive.ql.optimizer.spark.CombineEquivalentWorkResolver	CombineEquivalentWorkResolver searches inside SparkWork, finds and combines equivalent works.
org.apache.hadoop.hive.ql.optimizer.spark.SparkPartitionPruningSinkDesc	Description of spark partition pruning sink.
org.apache.hadoop.hive.ql.parse.AnalyzeCommandUtils	Utilities for command analysis.
org.apache.hadoop.hive.ql.parse.ColumnStatsAutoGatherContext	ColumnStatsAutoGatherContext is passed to the compiler when set hive.stats.autogather is true during the INSERT OVERWRITE command.
org.apache.hadoop.hive.ql.parse.MaskAndFilterInfo	Information for masking and filtering.
org.apache.hadoop.hive.ql.parse.TableMask	The main purpose for this class is for authorization.
org.apache.hadoop.hive.ql.parse.spark.SparkPartitionPruningSinkOperator	This operator gets partition info from the upstream operators and writes them to HDFS.
org.apache.hadoop.hive.ql.parse.spark.SplitOpTreeForDPP	This processor triggers on SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive.ql.plan.AbortTxnsDesc	Descriptor for aborting transactions.
org.apache.hadoop.hive.ql.plan.CacheMetadataDesc	Description for metadata cache.
org.apache.hadoop.hive.ql.plan.ShowCreateDatabaseDesc	Shows the name of the database.
org.apache.hadoop.hive.ql.plan.VectorPartitionConversion	PartitionConversion.
org.apache.hadoop.hive.ql.plan.VectorPartitionDesc	VectorMapDesc.
org.apache.hadoop.hive.ql.plan.VectorReduceSinkDesc	VectorReduceSinkDesc.
org.apache.hadoop.hive.ql.plan.VectorReduceSinkInfo	VectorGroupByAggregationInfo.
org.apache.hadoop.hive.ql.ppd.SimplePredicatePushDown	Implementation of predicate push down.
org.apache.hadoop.hive.ql.security.authorization.DefaultHiveAuthorizationTranslator	Default implementation of HiveAuthorizationTranslator.
org.apache.hadoop.hive.ql.security.authorization.plugin.AbstractHiveAuthorizer	Abstract class that extends HiveAuthorizer.
org.apache.hadoop.hive.ql.session.ClearDanglingScratchDir	A tool to remove dangling scratch directory.
org.apache.hadoop.hive.ql.stats.StatsCollectionContext	Creating context for stats collection.
org.apache.hadoop.hive.ql.txn.compactor.HouseKeeperServiceBase	Housekeeper for running services.
org.apache.hadoop.hive.ql.udf.UDFChr	UDFChr converts an integer into its ASCII equivalent.
org.apache.hadoop.hive.ql.udf.UDFCrc32	UDFCrc32.
org.apache.hadoop.hive.ql.udf.UDFMd5	UDFMd5.
org.apache.hadoop.hive.ql.udf.UDFReplace	UDFReplace replaces all substrings that are matched with a replacement substring.

Class	Description
org.apache.hadoop.hive.ql.udf.UDFSha1	UDFSha.
org.apache.hadoop.hive.ql.udf.UDFVersion	UDFVersion
org.apache.hadoop.hive.ql.udf.generic.BaseMaskUDF	User defined function for masking.
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFSumEmptyIsZero	User defined aggregation function for summing empty as zeros.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesBase	Base for user defined functions.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesDecrypt	User defined function for decryption.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesEncrypt	User defined function for encryption.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBRound	User defined function for banking rounding.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBaseNWayCompare	Base class for comparison UDF's (Greatest and Least).
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMask	User defined function for masking.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskFirstN	User defined function for masking first n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskHash	User defined function that returns a hashed value based on str.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskLastN	User defined function for masking last n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskShowFirstN	User defined function for showing masked first n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskShowLastN	User defined function for showing masked last n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFParamUtils	Generic UDF params utility class.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFQuarter	GenericUDFQuarter.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFRegexp	UDF to extract a specific group identified by a java regex.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFSha2	GenericUDFSha2.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFSubstringIndex	GenericUDFSubstringIndex.
org.apache.hadoop.hive.ql.udf.generic.GenericUDTFGetSplits	GenericUDTFGetSplits.
org.apache.hadoop.hive.ql.util.DependencyResolver	Query dependency resolver.
org.apache.hadoop.hive.ql.util.ResourceDownloader	Resource downloader.
org.apache.hadoop.hive.ql.util.TimestampUtils	Utilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive.serde2.DefaultFetchFormatter	Serializes row by user specified serde and calls toString() to make string type result.
org.apache.hadoop.hive.serde2.NoOpFetchFormatter	A No-op fetch formatter.

Class	Description
org.apache.hadoop.hive.serde2.binarysortable. BinarySortableSerDeWithEndPrefix	Serializer desrializer for binary sortable.
org.apache.hadoop.hive.serde2.thrift. ColumnBuffer	Column buffer.
org.apache.hadoop.hive.serde2.thrift. ThriftFormatter	Thrift formatter.
org.apache.hadoop.hive.serde2.thrift. ThriftJDBCBinarySerDe	Serializes the final output to thrift-able objects directly in the SerDe.
org.apache.hadoop.hive.thrift. HiveDelegationTokenManager	Delegation token manager.
org.apache.hive.beeline. ClientCommandHookFactory	Updates some client side information after executing some Hive commands.
org.apache.hive.beeline. ClientHook	This is the client's hook and used for new Hive CLI.
org.apache.hive.common.util. DateParser	Date parser class for Hive.
org.apache.hive.common.util. FixedSizedObjectPool	Simple object pool of limited size.
org.apache.hive.common.util. HashCodeUtil	Utilities for hash code.
org.apache.hive.common.util. IntervalDayTimeUtils	DateUtils.
org.apache.hive.hcatalog.streaming. AbstractRecordWriter	Class for defining record writer.
org.apache.hive.jdbc. HttpTokenAuthInterceptor	The class is instantiated with the username and password, it is then used to add header with these credentials to HTTP requests
org.apache.hive.jdbc. XsrfHttpRequestInterceptor	Http request interceptor for xsrf token.
org.apache.hive.service.cli.operation. GetCrossReferenceOperation	GetCrossReferenceOperation.
org.apache.hive.service.cli.operation. GetPrimaryKeysOperation	GetPrimaryKeysOperation.
org.apache.hive.service.cli.operation. SQLOperationDisplay	Used to display some info in the HS2 WebUI.
org.apache.hive.service.cli.operation. SQLOperationDisplayCache	Cache some SQLOperation information for WebUI
org.apache.hive.service.cli.thrift. RetryingThriftCLIServiceClient	RetryingThriftCLIServiceClient.

New Interfaces in Hive 2.1

Hive 2.1 includes the following new interfaces:

Interface	Description
org.apache.hadoop.hive.common. Pool	Simple object pool to prevent GC on small objects passed between threads.
org.apache.hadoop.hive.common.io. Allocator	An allocator provided externally to storage classes to allocate MemoryBuffer-s.
org.apache.hadoop.hive.common.io. DataCache	An abstract data cache that IO formats can use to retrieve and cache data.
org.apache.hadoop.hive.conf. HiveVariableSource	Getting hive variables.
org.apache.hadoop.hive.metastore. FileFormatProxy	Same as PartitionExpressionProxy, but for file format specific methods for metadata cache.

org.apache.hadoop.hive.metastore. HouseKeeperService	Runs arbitrary background logic inside the metastore service.
org.apache.hadoop.hive.metastore.txn. TxnStore	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive.ql.exec.tez. KeyValuesAdapter	Key-values interface for the Reader used by ReduceRecordSource
org.apache.hadoop.hive.ql.exec.vector.expressions. IStructInExpr	Interface used for both filter and non-filter versions of IN to simplify VectorizationContext code.
org.apache.hadoop.hive.ql.exec.vector.expressions. ITimestampInExpr	Interface used to process timestamp in expression.
org.apache.hadoop.hive.ql.io. ColumnarSplit	Interface when implemented should return the estimated size of columnar projections that will be read from the split.
org.apache.hadoop.hive.ql.io. LLapAwareSplit	Split that is aware that it could be executed in LLAP.
org.apache.hadoop.hive.ql.io. LLapWrappableInputFormatInterface	Marker interface for LLAP; serves no other purpose.
org.apache.hadoop.hive.ql.io. SelfDescribingInputFormatInterface	Marker interface to indicate a given input format is self-describing and can perform schema evolution itself.
org.apache.hadoop.hive.ql.io. StreamingOutputFormat	Marker interface for streaming output formats.
org.apache.hadoop.hive.ql.security.authorization.plugin. HiveAuthorizationTranslator	This interface has functions that provide the ability to customize the translation from Hive internal representations of Authorization objects to the public API objects This is an interface that is not meant for general use, it is targeted to some specific use cases of Apache Sentry (incubating).
org.apache.hadoop.hive.serde2. FetchFormatter	(For internal-use only) Used in ListSinkOperator for formatting final output.

Changed Classes in Hive 2.1

The following classes have changes in Hive 2.1:

Class	Description
org.apache.hadoop.hive.accumulo.mr. HiveAccumuloTableOutputFormat	Output format for accumulo tables.
org.apache.hadoop.hive.cli. CliDriver	CliDriver.
org.apache.hadoop.hive.cli. OptionsProcessor	OptionsProcessor.
org.apache.hadoop.hive.common. CompressionUtils	Contains methods used for the purposes of compression. This class should not be accessed from code run in Hadoop.
org.apache.hadoop.hive.common. FileUtils	Collection of file manipulation utilities common across Hive.
org.apache.hadoop.hive.common. HiveStatsUtils	HiveStatsUtils.
org.apache.hadoop.hive.common. JavaUtils	Collection of Java class loading/reflection related utilities common across Hive.
org.apache.hadoop.hive.common. LogUtils	Utilities common to logging operations.
org.apache.hadoop.hive.common. ObjectPair	Creating pair out of templates.
org.apache.hadoop.hive.common. ServerUtils	ServerUtils (specific to HiveServer version 1)

Class	Description
org.apache.hadoop.hive.common. StatsSetupConst	Defines the constant strings used by the statistics implementation.
org.apache.hadoop.hive.common. ValidReadTxnList	An implementation of org.apache.hadoop.hive.common.ValidTxnList for use by readers.
org.apache.hadoop.hive.common.cli. CommonCliOptions	Reusable code for Hive Cli's.
org.apache.hadoop.hive.common.io. NonSyncByteArrayInputStream	A thread-not-safe version of ByteArrayOutputStream, which removes all synchronized modifiers.
org.apache.hadoop.hive.common.type. HiveDecimal	HiveDecimal.
org.apache.hadoop.hive.common.type. HiveIntervalDayTime	Day-time interval type representing an offset in days/hours/minutes/seconds, with nanosecond precision.
org.apache.hadoop.hive.common.type. HiveVarchar	HiveVarChar.
org.apache.hadoop.hive.conf. HiveConf	Hive Configuration.
org.apache.hadoop.hive.conf. HiveConfUtil	Hive Configuration utils
org.apache.hadoop.hive.contrib.serde2. MultiDelimitSerDe	This SerDe allows user to use multiple characters as the field delimiter for a table.
org.apache.hadoop.hive.contrib.serde2. RegexSerDe	RegexSerDe uses regular expression (regex) to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2. TypedBytesSerDe	TypedBytesSerDe uses typed bytes to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2.s3. S3LogDeserializer	S3LogDeserializer.
org.apache.hadoop.hive.hbase. AbstractHBaseKeyPredicateDecomposer	Simple abstract class to help with creation of a DecomposedPredicate.
org.apache.hadoop.hive.hbase. CompositeHBaseKeyFactory	Factory that creates composite keys.
org.apache.hadoop.hive.hbase. HBaseLazyObjectFactory	Replaces original keyOI with OI which is create by HBaseKeyFactory provided by serde property for hbase.
org.apache.hadoop.hive.hbase. HBaseSerDe	HBaseSerDe can be used to serialize object into an HBase table and deserialize objects from an HBase table.
org.apache.hadoop.hive.hbase. HBaseSerDeHelper	Helper class for HBaseSerDe
org.apache.hadoop.hive.hbase. HiveHBaseTableInputFormat	HiveHBaseTableInputFormat implements InputFormat for HBase storage handler tables, decorating an underlying HBase TableInputFormat with extra Hive logic such as column pruning and filter pushdown.
org.apache.hadoop.hive.hbase. HiveHBaseTableOutputFormat	HiveHBaseTableOutputFormat implements HiveOutputFormat for HBase tables.
org.apache.hadoop.hive.hbase. LazyHBaseCellMap	LazyHBaseCellMap refines LazyMap with HBase column mapping.
org.apache.hadoop.hive.hwi. HWIContextListener	After getting a contextInitialized event, this component starts an instance of the HiveSessionManager.
org.apache.hadoop.hive.hwi. HWIServer	This is the entry point for HWI.
org.apache.hadoop.hive.hwi. HWISessionItem	HWISessionItem can be viewed as a wrapper for a Hive shell.

Class	Description
org.apache.hadoop.hive.hwi.HWISessionManager	HiveSessionManager is a Runnable started inside a web application context.
org.apache.hadoop.hive.metastore.Deadline	Monitors long running methods in a thread.
org.apache.hadoop.hive.metastore.HiveAlterHandler	Hive specific implementation of alter.
org.apache.hadoop.hive.metastore.HiveMetaStore	Removes application logic to a separate interface.
org.apache.hadoop.hive.metastore.HiveMetaStoreClient	Hive Metastore Client.
org.apache.hadoop.hive.metastore.HiveMetaStoreFsImpl	Class to handle methods for filesystem and data related to metastore.
org.apache.hadoop.hive.metastore.LockComponentBuilder	A builder for LockComponents.
org.apache.hadoop.hive.metastore.LockRequestBuilder	Builder class to make constructing LockRequest easier.
org.apache.hadoop.hive.metastore.MetaStoreSchemaInfo	Information about metastore schemas stored in database.
org.apache.hadoop.hive.metastore.MetaStoreUtils	Utilities to handle metastore data.
org.apache.hadoop.hive.metastore.ObjectStore	Interface between the application logic and the database store that contains the objects.
org.apache.hadoop.hive.metastore.PartitionDropOptions	Generalizes the switches for dropPartitions().
org.apache.hadoop.hive.metastore.RetryingHMSHandler	Handler for hive metastore.
org.apache.hadoop.hive.metastore.RetryingMetaStoreClient	RetryingMetaStoreClient.
org.apache.hadoop.hive.metastore.StatObjectConverter	Contains conversion logic that creates Thrift stat objects from JDO stat objects and plain arrays from DirectSQL.
org.apache.hadoop.hive.metastore.Warehouse	Represents a warehouse where data of Hive tables is stored.
org.apache.hadoop.hive.metastore.api.AbortTxnRequest	Aborting transaction request.
org.apache.hadoop.hive.metastore.api.AddDynamicPartitions	Adding dynamic partitions.
org.apache.hadoop.hive.metastore.api.AddPartitionsRequest	Adding partition request.
org.apache.hadoop.hive.metastore.api.AddPartitionsResult	Adding partition result.
org.apache.hadoop.hive.metastore.api.AggrStats	Aggregation statistics.
org.apache.hadoop.hive.metastore.api.BinaryColumnStatsData	Binary column statistics data.
org.apache.hadoop.hive.metastore.api.BooleanColumnStatsData	Boolean column statistics data.
org.apache.hadoop.hive.metastore.api.CheckLockRequest	Checking request on acquiring lock.
org.apache.hadoop.hive.metastore.api.ColumnStatistics	Column statistics class.
org.apache.hadoop.hive.metastore.api.ColumnStatisticsDesc	Column statistics description.
org.apache.hadoop.hive.metastore.api.ColumnStatisticsObject	Column statistics object.

Class	Description
org.apache.hadoop.hive.metastore.api. CommitTxnRequest	Commit transaction request.
org.apache.hadoop.hive.metastore.api. CompactionRequest	Compaction request.
org.apache.hadoop.hive.metastore.api. CurrentNotificationEventId	Current notification event ID.
org.apache.hadoop.hive.metastore.api. Database	Class that describes database.
org.apache.hadoop.hive.metastore.api. Date	Date class.
org.apache.hadoop.hive.metastore.api. DateColumnStatsData	Date column statistics data.
org.apache.hadoop.hive.metastore.api. Decimal	Handling decimal type.
org.apache.hadoop.hive.metastore.api. DecimalColumnStatsData	Decimal column statistics data.
org.apache.hadoop.hive.metastore.api. DoubleColumnStatsData	Double column statistics data.
org.apache.hadoop.hive.metastore.api. DropPartitionsExpr	Drop partitions expression.
org.apache.hadoop.hive.metastore.api. DropPartitionsRequest	Drop partitions request.
org.apache.hadoop.hive.metastore.api. DropPartitionsResult	Drop partitions result.
org.apache.hadoop.hive.metastore.api. EnvironmentContext	Environment context structure.
org.apache.hadoop.hive.metastore.api. FieldSchema	Field schema structure.
org.apache.hadoop.hive.metastore.api. FireEventRequest	Fire event request.
org.apache.hadoop.hive.metastore.api. FireEventResponse	Fire event response.
org.apache.hadoop.hive.metastore.api. Function	Function structure.
org.apache.hadoop.hive.metastore.api. GetOpenTxnsInfoResponse	Getter for open transactions information about response.
org.apache.hadoop.hive.metastore.api. GetOpenTxnsResponse	Getter for open transactions response.
org.apache.hadoop.hive.metastore.api. GetPrincipalsInRoleRequest	Getting request for principals in role.
org.apache.hadoop.hive.metastore.api. GetPrincipalsInRoleResponse	Getting response for principals in role.
org.apache.hadoop.hive.metastore.api. GetRoleGrantsForPrincipalRequest	Getting request for granting role for principal.
org.apache.hadoop.hive.metastore.api. GetRoleGrantsForPrincipalResponse	Getting response for granting role for principal.
org.apache.hadoop.hive.metastore.api. GrantRevokePrivilegeRequest	Request for revoking granted privilege.
org.apache.hadoop.hive.metastore.api. GrantRevokePrivilegeResponse	Response for revoking granted privilege.

Class	Description
org.apache.hadoop.hive.metastore.api. GrantRevokeRoleRequest	Request for revoking granted role.
org.apache.hadoop.hive.metastore.api. GrantRevokeRoleResponse	Response for revoking granted role.
org.apache.hadoop.hive.metastore.api. HeartbeatRequest	Request for heartbeat.
org.apache.hadoop.hive.metastore.api. HeartbeatTxnRangeRequest	Request for transaction range request.
org.apache.hadoop.hive.metastore.api. HeartbeatTxnRangeResponse	Response for transaction range response.
org.apache.hadoop.hive.metastore.api. HiveObjectPrivilege	Description of privileges for hive object.
org.apache.hadoop.hive.metastore.api. HiveObjectRef	Hive object reference.
org.apache.hadoop.hive.metastore.api. Index	Description of index.
org.apache.hadoop.hive.metastore.api. InsertEventRequestData	Class to handle data about insert event on request.
org.apache.hadoop.hive.metastore.api. LockComponent	Description of lock component.
org.apache.hadoop.hive.metastore.api. LockRequest	Description of lock request.
org.apache.hadoop.hive.metastore.api. LockResponse	Description of lock response.
org.apache.hadoop.hive.metastore.api. LongColumnStatsData	Description of long column statistics data.
org.apache.hadoop.hive.metastore.api. NotificationEvent	Description of notification event.
org.apache.hadoop.hive.metastore.api. NotificationEventRequest	Description of notification event on request.
org.apache.hadoop.hive.metastore.api. NotificationEventResponse	Description of notification event on response.
org.apache.hadoop.hive.metastore.api. OpenTxnRequest	Description of open transactions on request.
org.apache.hadoop.hive.metastore.api. OpenTxnsResponse	Description of open transactions on response.
org.apache.hadoop.hive.metastore.api. Order	Description of order.
org.apache.hadoop.hive.metastore.api. Partition	Description of partition.
org.apache.hadoop.hive.metastore.api. PartitionListComposingSpec	Description of partition list composing specification.
org.apache.hadoop.hive.metastore.api. PartitionSpec	Description of partition specification.
org.apache.hadoop.hive.metastore.api. PartitionSpecWithSharedSD	Description of partition specification with shared sd.
org.apache.hadoop.hive.metastore.api. PartitionWithoutSD	Description of partition without sd.
org.apache.hadoop.hive.metastore.api. PartitionsByExprRequest	Description of partitions by expression request.
org.apache.hadoop.hive.metastore.api. PartitionsByExprResult	Description of partitions by expression result.
org.apache.hadoop.hive.metastore.api. PartitionsStatsRequest	Description of partition statistics request.

Class	Description
org.apache.hadoop.hive.metastore.api.PartitionsStatsResult	Description of partitions statistics result.
org.apache.hadoop.hive.metastore.api.PrincipalPrivilegeSet	Description of setting principal privilege.
org.apache.hadoop.hive.metastore.api.PrivilegeBag	Description of privilege bag.
org.apache.hadoop.hive.metastore.api.PrivilegeGrantInfo	Description of granted privilege info.
org.apache.hadoop.hive.metastore.api.ResourceUri	Description of resource URI.
org.apache.hadoop.hive.metastore.api.Role	Description of role.
org.apache.hadoop.hive.metastore.api.RolePrincipalGrant	Description of granted principal role.
org.apache.hadoop.hive.metastore.api.Schema	Description of schema.
org.apache.hadoop.hive.metastore.api.SerDelInfo	Description of serializer deserializer information.
org.apache.hadoop.hive.metastore.api.SetPartitionsStatsRequest	Description of setting partition statistics on request.
org.apache.hadoop.hive.metastore.api.ShowCompactRequest	Show compaction on request.
org.apache.hadoop.hive.metastore.api.ShowCompactResponse	Show compaction on response.
org.apache.hadoop.hive.metastore.api.ShowCompactResponseElement	Show compaction response element.
org.apache.hadoop.hive.metastore.api.ShowLocksRequest	Show locks on request.
org.apache.hadoop.hive.metastore.api.ShowLocksResponse	Show locks on response.
org.apache.hadoop.hive.metastore.api.ShowLocksResponseElement	Show locks response element.
org.apache.hadoop.hive.metastore.api.SkewedInfo	Description for skewed information.
org.apache.hadoop.hive.metastore.api.StorageDescriptor	Description for storage descriptor.
org.apache.hadoop.hive.metastore.api.StringColumnStatisticsData	Description for string column statistics data.
org.apache.hadoop.hive.metastore.api.Table	Description for data.
org.apache.hadoop.hive.metastore.api.TableStatsRequest	Description for table statistics request.
org.apache.hadoop.hive.metastore.api.TableStatsResult	Description for table statistics result.
org.apache.hadoop.hive.metastore.api.AlreadyExistsException	Custom exception to handle already exists error.
org.apache.hadoop.hive.metastore.api.ConfigValSecurityException	Custom exception to handle configuration value security error.
org.apache.hadoop.hive.metastore.api.IndexAlreadyExistsException	Custom exception to handle index already exists error.
org.apache.hadoop.hive.metastore.api.InvalidInputException	Custom exception for invalid input error.
org.apache.hadoop.hive.metastore.api.InvalidObjectException	Custom exception for invalid object error.

Class	Description
org.apache.hadoop.hive.metastore.api.InvalidOperationException	Custom exception for invalid operation error.
org.apache.hadoop.hive.metastore.api.InvalidPartitionException	Custom exception for invalid partition error.
org.apache.hadoop.hive.metastore.api.MetaException	Custom exception for metastore related error.
org.apache.hadoop.hive.metastore.api.NoSuchLockException	Custom exception in case of invalid lock.
org.apache.hadoop.hive.metastore.api.NoSuchObjectException	Custom exception in case of invalid object.
org.apache.hadoop.hive.metastore.api.NoSuchTxnException	Custom exception in case of invalid transaction.
org.apache.hadoop.hive.metastore.api.TxnAbortedException	Custom exception in case of aborted transaction.
org.apache.hadoop.hive.metastore.api.TxnOpenException	Custom exception in case of not close transaction.
org.apache.hadoop.hive.metastore.api.UnknownDBException	Custom exception in case of unknown database.
org.apache.hadoop.hive.metastore.api.UnknownPartitionException	Custom exception in case of unknown partition.
org.apache.hadoop.hive.metastore.api.UnknownTableException	Custom partition in case of unknown table.
org.apache.hadoop.hive.metastore.events.EventCleanerTask	Cleaning tasks from event table.
org.apache.hadoop.hive.metastore.parser.ExpressionTree	Represents the filter as a binary tree.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Information on a possible or running compaction.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Utility methods for creating and destroying txn database/schema, plus methods for querying against metastore tables.
org.apache.hadoop.hive.ql.Context	Context for Semantic Analyzers.
org.apache.hadoop.hive.ql.Driver	Driver to process commands on cluster.
org.apache.hadoop.hive.ql.QueryPlan	QueryPlan can be serialized to disk to restart/resume the progress of it in the future, either within or outside of the current JVM.
org.apache.hadoop.hive.ql.QueryProperties	QueryProperties.
org.apache.hadoop.hive.ql.exec.AbstractFileMergeOperator	Fast file merge operator for ORC and RCfile.
org.apache.hadoop.hive.ql.exec.AbstractMapJoinOperator	Class to handle join input's join keys.
org.apache.hadoop.hive.ql.exec.AppMasterEventOperator	AppMasterEventOperator sends any rows it receives to the Tez AM.
org.apache.hadoop.hive.ql.exec.AutoProgressor	AutoProgressor periodically sends updates to the job tracker so that it doesn't consider this task attempt dead if there is a long period of inactivity.
org.apache.hadoop.hive.ql.exec.CollectOperator	Buffers rows emitted by other operators.
org.apache.hadoop.hive.ql.exec.ColumnStatsTask	ColumnStatsTask implementation.

Class	Description
org.apache.hadoop.hive.ql.exec. ColumnStatsUpdateTask	ColumnStatsUpdateTask implementation.
org.apache.hadoop.hive.ql.exec. CommonJoinOperator	Join operator implementation.
org.apache.hadoop.hive.ql.exec. CommonMergeJoinOperator	Consolidate the join algorithms to either hash based joins (MapJoinOperator) or sort-merge based joins, this operator is being introduced.
org.apache.hadoop.hive.ql.exec. ConditionalTask	Conditional Task implementation.
org.apache.hadoop.hive.ql.exec. DDLTask	DDLTask implementation.
org.apache.hadoop.hive.ql.exec. DefaultBucketMatcher	Finding right bucket.
org.apache.hadoop.hive.ql.exec. DemuxOperator	DemuxOperator is an operator used by MapReduce Jobs optimized by CorrelationOptimizer.
org.apache.hadoop.hive.ql.exec. DummyStoreOperator	For SortMerge joins, this is a dummy operator, which stores the row for the small table before it reaches the sort merge join operator.
org.apache.hadoop.hive.ql.exec. ExplainTask	ExplainTask implementation.
org.apache.hadoop.hive.ql.exec. FetchOperator	FetchTask implementation.
org.apache.hadoop.hive.ql.exec. FetchTask	FetchTask implementation.
org.apache.hadoop.hive.ql.exec. FileSinkOperator	File Sink operator implementation.
org.apache.hadoop.hive.ql.exec. FilterOperator	Filter operator implementation.
org.apache.hadoop.hive.ql.exec. ForwardOperator	Forward Operator Just forwards.
org.apache.hadoop.hive.ql.exec. FunctionRegistry	FunctionRegistry.
org.apache.hadoop.hive.ql.exec. FunctionTask	FunctionTask.
org.apache.hadoop.hive.ql.exec. GroupByOperator	GroupBy operator implementation.
org.apache.hadoop.hive.ql.exec. HashTableDummyOperator	Hash table operator implementation.
org.apache.hadoop.hive.ql.exec. HashTableSinkOperator	Hash table sink operator implementation.
org.apache.hadoop.hive.ql.exec. JoinOperator	Join operator implementation.
org.apache.hadoop.hive.ql.exec. LateralViewForwardOperator	LateralViewForwardOperator.
org.apache.hadoop.hive.ql.exec. LateralViewJoinOperator	The lateral view join operator is used for FROM src LATERAL VIEW udtf()...
org.apache.hadoop.hive.ql.exec. LimitOperator	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive.ql.exec. ListSinkOperator	For fetch task with operator tree, row read from FetchOperator is processed via operator tree and finally arrives to this operator.
org.apache.hadoop.hive.ql.exec. MapJoinOperator	Map side Join operator implementation.
org.apache.hadoop.hive.ql.exec. MapOperator	Map operator.
org.apache.hadoop.hive.ql.exec. MapredContext	Runtime context of MapredTask providing additional information to GenericUDF
org.apache.hadoop.hive.ql.exec. MoveTask	MoveTask implementation.
org.apache.hadoop.hive.ql.exec. MuxOperator	MuxOperator is used in the Reduce side of MapReduce jobs optimized by Correlation Optimizer.

Class	Description
org.apache.hadoop.hive.ql.exec. ObjectCacheFactory	ObjectCacheFactory returns the appropriate cache depending on settings in the hive conf.
org.apache.hadoop.hive.ql.exec. Operator	Base operator implementation.
org.apache.hadoop.hive.ql.exec. OperatorFactory	OperatorFactory.
org.apache.hadoop.hive.ql.exec. OperatorUtils	Utilities to handle operators.
org.apache.hadoop.hive.ql.exec. OrcFileMergeOperator	Fast file merge operator for ORC files.
org.apache.hadoop.hive.ql.exec. PTFOperator	Class to handle partitioned table functions operators.
org.apache.hadoop.hive.ql.exec. PTFPartition	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive.ql.exec. PTFRollingPartition	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive.ql.exec. PTFUtils	Utilities to handle partitioned table functions.
org.apache.hadoop.hive.ql.exec. PartitionKeySampler	Class to handle partition key sampler.
org.apache.hadoop.hive.ql.exec. RCFileMergeOperator	Fast file merge operator for RC files.
org.apache.hadoop.hive.ql.exec. ReduceSinkOperator	Reduce Sink Operator sends output to the reduce stage.
org.apache.hadoop.hive.ql.exec. Registry	Function registry.
org.apache.hadoop.hive.ql.exec. SMBMapJoinOperator	Sorted Merge Map Join Operator.
org.apache.hadoop.hive.ql.exec. ScriptOperator	ScriptOperator.
org.apache.hadoop.hive.ql.exec. SelectOperator	Select operator implementation.
org.apache.hadoop.hive.ql.exec. SkewJoinHandler	At runtime in Join, output big keys in one table into one corresponding directories, and all same keys in other tables into different dirs (one for each table).
org.apache.hadoop.hive.ql.exec. SparkHashTableSinkOperator	Operator for spark hashtable sink.
org.apache.hadoop.hive.ql.exec. StatsNoJobTask	StatsNoJobTask is used in cases where stats collection is the only task for the given query (no parent MR or Tez job).
org.apache.hadoop.hive.ql.exec. TableScanOperator	Table Scan Operator If the data is coming from the map-reduce framework, just forward it.
org.apache.hadoop.hive.ql.exec. Task	Task implementation.
org.apache.hadoop.hive.ql.exec. TaskResult	TaskResult implementation.
org.apache.hadoop.hive.ql.exec. TemporaryHashSinkOperator	Operator temporary hash sink.
org.apache.hadoop.hive.ql.exec. TerminalOperator	Terminal Operator Base Class.
org.apache.hadoop.hive.ql.exec. TezDummyStoreOperator	A dummy store operator same as the dummy store operator but for tez.
org.apache.hadoop.hive.ql.exec. TopNHash	Stores binary key/value in sorted manner to get top-n key/value TODO: rename to TopNHeap?
org.apache.hadoop.hive.ql.exec. UDTFOperator	UDTFOperator.
org.apache.hadoop.hive.ql.exec. UnionOperator	Union Operator Just forwards.
org.apache.hadoop.hive.ql.exec. Utilities	Utilities.

Class	Description
org.apache.hadoop.hive.ql.exec.mr. ExecDriver	ExecDriver is the central class in co-ordinating execution of any map-reduce task.
org.apache.hadoop.hive.ql.exec.mr. ExecMapper	ExecMapper is the generic Map class for Hive.
org.apache.hadoop.hive.ql.exec.mr. ExecMapperContext	ExecMapperContext is the generic Map context class for Hive.
org.apache.hadoop.hive.ql.exec.mr. HadoopJobExecHelper	Handle information about hadoop job.
org.apache.hadoop.hive.ql.exec.mr. JobDebugger	JobDebugger takes a RunningJob that has failed and grabs the top 4 failing tasks and outputs this information to the Hive CLI.
org.apache.hadoop.hive.ql.exec.mr. MapredLocalTask	MapredLocalTask represents any local work (i.e.: client side work) that hive needs to execute.
org.apache.hadoop.hive.ql.exec.mr. Throttle	Intelligence to make clients wait if the cluster is in a bad state.
org.apache.hadoop.hive.ql.exec.persistence. BytesBytesMultiHashMap	HashMap that maps byte arrays to byte arrays with limited functionality necessary for MapJoin hash tables, with small memory overhead.
org.apache.hadoop.hive.ql.exec.persistence. HashMapWrapper	Simple wrapper for persistent Hashmap implementing only the put/get/remove/clear interface.
org.apache.hadoop.hive.ql.exec.persistence. HybridHashTableContainer	Hash table container that can have many partitions -- each partition has its own hashmap, as well as row container for small table and big table.
org.apache.hadoop.hive.ql.exec.persistence. KeyValueContainer	An eager key/value container that puts every row directly to output stream.
org.apache.hadoop.hive.ql.exec.persistence. MapJoinBytesTableContainer	Table container that serializes keys and values using LazyBinarySerDe into BytesBytesMultiHashMap, with very low memory overhead.
org.apache.hadoop.hive.ql.exec.persistence. MapJoinKey	The base class for MapJoinKey.
org.apache.hadoop.hive.ql.exec.persistence. MapJoinTableContainerSerDe	Serialization/deserialization of table container for join.
org.apache.hadoop.hive.ql.exec.persistence. ObjectContainer	An eager object container that puts every row directly to output stream.
org.apache.hadoop.hive.ql.exec.persistence. RowContainer	Simple persistent container for rows.
org.apache.hadoop.hive.ql.exec.persistence. UnwrapRowContainer	Unwraps values from current key with valueIndex in mapjoin desc.
org.apache.hadoop.hive.ql.exec.spark. GroupByShuffler	Shuffle group by operator.
org.apache.hadoop.hive.ql.exec.spark. HiveSparkClientFactory	Factory class for spark client.
org.apache.hadoop.hive.ql.exec.spark. LocalHiveSparkClient	LocalSparkClient submit Spark job in local driver, it's responsible for build spark client environment and execute spark work.
org.apache.hadoop.hive.ql.exec.spark. MapInput	Input for mapper.
org.apache.hadoop.hive.ql.exec.spark. MapTran	Mapper tran.
org.apache.hadoop.hive.ql.exec.spark. ReduceTran	Reduce tran.

Class	Description
org.apache.hadoop.hive.ql.exec.spark. RemoteHiveSparkClient	RemoteSparkClient is a wrapper of org.apache.hive.spark.client.SparkClient, which wrap a spark job request and send to an remote SparkContext.
org.apache.hadoop.hive.ql.exec.spark. ShuffleTran	Shuffle tran.
org.apache.hadoop.hive.ql.exec.spark. SortByShuffler	Sorting class for shuffler.
org.apache.hadoop.hive.ql.exec.spark. SparkTask	Description of spark task.
org.apache.hadoop.hive.ql.exec.spark. SparkUtilities	Contains utilities methods used as part of Spark tasks.
org.apache.hadoop.hive.ql.exec.spark.session. SparkSessionImpl	Implementation of spark session.
org.apache.hadoop.hive.ql.exec.spark.status.impl. JobMetricsListener	Listener for job metrics.
org.apache.hadoop.hive.ql.exec.spark.status.impl. LocalSparkJobStatus	Spark job local status.
org.apache.hadoop.hive.ql.exec.spark.status.impl. RemoteSparkJobStatus	Used with remove spark client.
org.apache.hadoop.hive.ql.exec.tez. DagUtils	DagUtils.
org.apache.hadoop.hive.ql.exec.tez. DynamicPartitionPruner	DynamicPartitionPruner takes a list of assigned partitions at runtime (split generation) and prunes them using events generated during execution of the dag.
org.apache.hadoop.hive.ql.exec.tez. HiveSplitGenerator	Generates splits inside the AM on the cluster.
org.apache.hadoop.hive.ql.exec.tez. MapRecordProcessor	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. MapRecordSource	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. MergeFileRecordProcessor	Record processor for fast merging of files.
org.apache.hadoop.hive.ql.exec.tez. RecordProcessor	Process input from tez LogicalInput and write output It has different subclasses for map and reduce processing
org.apache.hadoop.hive.ql.exec.tez. ReduceRecordProcessor	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. ReduceRecordSource	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. SplitGrouper	SplitGrouper is used to combine splits based on head room and locality.
org.apache.hadoop.hive.ql.exec.tez. TezJobMonitor	TezJobMonitor keeps track of a tez job while it's being executed.
org.apache.hadoop.hive.ql.exec.tez. TezProcessor	Hive processor for Tez that forms the vertices in Tez and processes the data.
org.apache.hadoop.hive.ql.exec.tez. TezSessionPoolManager	This class is for managing multiple tez sessions particularly when HiveServer2 is being used to submit queries.
org.apache.hadoop.hive.ql.exec.tez. TezSessionState	Holds session state related to Tez

Class	Description
org.apache.hadoop.hive.ql.exec.tez. TezTask	TezTask handles the execution of TezWork.
org.apache.hadoop.hive.ql.exec.tez.tools. KeyValueInputMerger	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive.ql.exec.tez.tools. KeyValuesInputMerger	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive.ql.exec.vector. BytesColumnVector	This class supports string and binary data by value reference.
org.apache.hadoop.hive.ql.exec.vector. ColumnVector	ColumnVector contains the shared structure for the sub-types, including NULL information, and whether this vector repeats, i.e.
org.apache.hadoop.hive.ql.exec.vector. DecimalColumnVector	A vector of HiveDecimalWritable objects.
org.apache.hadoop.hive.ql.exec.vector. DoubleColumnVector	This class represents a nullable double precision floating point column vector.
org.apache.hadoop.hive.ql.exec.vector. LongColumnVector	This class represents a nullable int column vector.
org.apache.hadoop.hive.ql.exec.vector. TimestampUtils	Utilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive.ql.exec.vector. VectorAppMasterEventOperator	App Master Event operator implementation.
org.apache.hadoop.hive.ql.exec.vector. VectorAssignRow	This class assigns specified columns of a row from a Writable row objects.
org.apache.hadoop.hive.ql.exec.vector. VectorColumnOrderedMap	This class collects column information for mapping vector columns, including the hive type name.
org.apache.hadoop.hive.ql.exec.vector. VectorColumnInfo	Class to keep information on a set of typed vector columns.
org.apache.hadoop.hive.ql.exec.vector. VectorCopyRow	This class copies specified columns of a row from one VectorizedRowBatch to another.
org.apache.hadoop.hive.ql.exec.vector. VectorDeserializeRow	This class deserializes a serialization format into a row of a VectorizedRowBatch.
org.apache.hadoop.hive.ql.exec.vector. VectorExtractRow	This class extracts specified VectorizedRowBatch row columns into writables.
org.apache.hadoop.hive.ql.exec.vector. VectorFileSinkOperator	File Sink operator implementation.
org.apache.hadoop.hive.ql.exec.vector. VectorFilterOperator	Filter operator implementation.
org.apache.hadoop.hive.ql.exec.vector. VectorGroupByOperator	Vectorized GROUP BY operator implementation.
org.apache.hadoop.hive.ql.exec.vector. VectorHashKeyWrapper	A hash map key wrapper for vectorized processing.
org.apache.hadoop.hive.ql.exec.vector. VectorLimitOperator	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive.ql.exec.vector. VectorMapJoinBaseOperator	The *NON-NATIVE* base vector map join operator class used by VectorMapJoinOperator and VectorMapJoinOuterFilteredOperator.

Class	Description
org.apache.hadoop.hive.ql.exec.vector. VectorMapJoinOperator	The vectorized version of the MapJoinOperator.
org.apache.hadoop.hive.ql.exec.vector. VectorMapJoinOuterFilteredOperator	This is the *NON-NATIVE* vector map join operator for just LEFT OUTER JOIN and filtered.
org.apache.hadoop.hive.ql.exec.vector. VectorMapOperator	The vectorized MapOperator.
org.apache.hadoop.hive.ql.exec.vector. VectorReduceSinkOperator	The vectorized reduce sink operator.
org.apache.hadoop.hive.ql.exec.vector. VectorSMBMapJoinOperator	VectorSMBJoinOperator.
org.apache.hadoop.hive.ql.exec.vector. VectorSelectOperator	Select operator implementation.
org.apache.hadoop.hive.ql.exec.vector. VectorSerializeRow	This class serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive.ql.exec.vector. VectorizationContext	Context class for vectorization execution.
org.apache.hadoop.hive.ql.exec.vector. VectorizedBatchUtil	The vectorized MapOperator.
org.apache.hadoop.hive.ql.exec.vector. VectorizedRowBatch	A VectorizedRowBatch is a set of rows, organized with each column as a vector.
org.apache.hadoop.hive.ql.exec.vector. VectorizedRowBatchCtx	Context for Vectorized row batch.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastDecimalToTimestamp	Type cast decimal to timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToDecimal	To be used to cast timestamp to decimal.
org.apache.hadoop.hive.ql.exec.vector.expressions. ColAndCol	Evaluate AND of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive.ql.exec.vector.expressions. ColOrCol	Evaluate OR of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive.ql.exec.vector.expressions. ConstantVectorExpression	Constant is represented as a vector with repeating values.
org.apache.hadoop.hive.ql.exec.vector.expressions. DecimalUtil	Utility functions for vector operations on decimal values.
org.apache.hadoop.hive.ql.exec.vector.expressions. FilterExprOrExpr	Represents an Or expression.
org.apache.hadoop.hive.ql.exec.vector.expressions. FilterStringColumnInList	Evaluate an IN filter on a batch for a vector of strings.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncRoundWithNumDigitsDecimalToDecimal	Function for rounding decimals.
org.apache.hadoop.hive.ql.exec.vector.expressions. MathExpr	Math expression evaluation helper functions.
org.apache.hadoop.hive.ql.exec.vector.expressions. NullUtil	Utility functions to handle null propagation.
org.apache.hadoop.hive.ql.exec.vector.expressions. StringColumnInList	Evaluate an IN boolean expression (not a filter) on a batch for a vector of strings.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions. String Expr	String expression evaluation helper functions.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDateAddColCol	Vectorized user defined function for adding columns.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDateAddColScalar	Vectorized user defined function for adding column and scalar.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDateDiffColCol	Vectorized user defined function for finding difference between two columns.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDateLong	Vectorized version of TO_DATE(TIMESTAMP)/TO_DATE(DATE).
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDateString	Vectorized version of TO_DATE(STRING) As TO_DATE() now returns DATE type, this should be the same behavior as the DATE cast operator.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinCommonOperator	Common operator class for native vectorized map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinGenerateResultOperator	Contains methods for generating vectorized join results and forwarding batches.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyGenerateResultOperator	This class has methods for generating vectorized join results for the big table only variation of inner joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyLongOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyMultiKeyOperator	Specialized class for doing a vectorized map join that is an inner join on Multi-Key and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyStringOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerGenerateResultOperator	Contains methods for generating vectorized join results for inner joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerLongOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerMultiKeyOperator	Specialized class for doing a vectorized map join that is an inner join on a Multi-Key using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinInnerStringOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinLeftSemiGenerateResultOperator	Contains methods for generating vectorized join results for left semi joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinLeftSemiLongOperator	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column Long using a hash set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinLeftSemiMultiKeyOperator	Specialized class for doing a vectorized map join that is an left semi join on Multi-Key using hash set.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinLeftSemiStringOperator	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column String using a hash set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterGenerateResultOperator	Contains methods for generating vectorized join results for outer joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterLongOperator	Specialized class for doing a vectorized map join that is an outer join on a Single-Column Long using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterMultiKeyOperator	Specialized class for doing a vectorized map join that is an outer join on Multi-Key using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterStringOperator	Specialized class for doing a vectorized map join that is an outer join on a Single-Column String using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinRowBytesContainer	An eager bytes container that puts row bytes to an output stream.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashMap	Bytes key hash map optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash map implementations.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashMultiSet	Bytes key hash multi-set optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash multi-set implementations.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashUtil	Utilities for bytes key hash multi-set optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastHashTable	Vector map join fast hash table.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastKeyStore	Vector map join fast key store.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashMap	Vector map join fast long hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashMultiSet	Vector map join fast long hash multi set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashSet	A single LONG key hash set optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashTable	A single long value map optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashUtil	Utilities for vector map join of single long value.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashMap	A multi-key value hash map optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashMultiSet	A multi-key hash multi-set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashSet	A multi-key hash set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastStringCommon	A single byte array value hash map optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastTableContainer	HashTableLoader for Tez constructs the hashtable from records read from a broadcast edge.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable. VectorMapJoinHashMapResult	Abstract class for a hash map result. For reading the values, one-by-one.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable. VectorMapJoinHashTableResult	Root abstract class for a hash table result.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.optimized. VectorMapJoinOptimizedCreateHashTable	Create hash table for vector map join.
org.apache.hadoop.hive.ql.hooks. HookContext	Hook Context keeps all the necessary information for all the hooks.
org.apache.hadoop.hive.ql.hooks. PostExecutePrinter	Implementation of a post execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.hooks. PreExecutePrinter	Implementation of a pre execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.index. HiveIndex	Holds index related constants.
org.apache.hadoop.hive.ql.index. HiveIndexQueryContext	Used to pass information between the IndexProcessor and the plugin IndexHandler during query processing
org.apache.hadoop.hive.ql.index. HiveIndexResult	HiveIndexResult parses the input stream from an index query to generate a list of file splits to query.
org.apache.hadoop.hive.ql.index. HiveIndexedInputFormat	Input format for doing queries that use indexes.
org.apache.hadoop.hive.ql.index. IndexPredicateAnalyzer	IndexPredicateAnalyzer decomposes predicates, separating the parts which can be satisfied by an index from the parts which cannot.
org.apache.hadoop.hive.ql.index. IndexSearchCondition	IndexSearchCondition represents an individual search condition found by IndexPredicateAnalyzer.
org.apache.hadoop.hive.ql.index. TableBasedIndexHandler	Index handler for indexes that use tables to store indexes.
org.apache.hadoop.hive.ql.index.compact. HiveCompactIndexInputFormat	Hive compact index input format.
org.apache.hadoop.hive.ql.io. AcidUtils	Utilities that are shared by all of the ACID input and output formats.
org.apache.hadoop.hive.ql.io. BucketizedHiveInputFormat	BucketizedHiveInputFormat serves the similar function as hiveInputFormat but its getSplits() always group splits from one input file into one wrapper split.
org.apache.hadoop.hive.ql.io. CombineHiveInputFormat	CombineHiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io. HiveFileFormatUtils	An util class for various Hive file format tasks.
org.apache.hadoop.hive.ql.io. HiveInputFormat	HiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io. IOConstants	Input output constants.
org.apache.hadoop.hive.ql.io. IOContext	IOContext basically contains the position information of the current key/value.
org.apache.hadoop.hive.ql.io. NullRowsInputFormat	NullRowsInputFormat outputs null rows, maximum 100.
org.apache.hadoop.hive.ql.io. OneNullRowInputFormat	OneNullRowInputFormat outputs one null row.

Class	Description
org.apache.hadoop.hive.ql.io.RCFileInputFormat	RCFileInputFormat.
org.apache.hadoop.hive.ql.io.SequenceFileInputFormatChecker	SequenceFileInputFormatChecker.
org.apache.hadoop.hive.ql.io.avro.AvroContainerOutputFormat	Write to an Avro file from a Hive process.
org.apache.hadoop.hive.ql.io.merge.MergeFileMapper	Mapper for fast file merging of ORC and RC files.
org.apache.hadoop.hive.ql.io.merge.MergeFileTask	Task for fast merging of ORC and RC files.
org.apache.hadoop.hive.ql.io.orc.CompressionKind	An enumeration that lists the generic compression algorithms that can be applied to ORC files.
org.apache.hadoop.hive.ql.io.orc.OrcFile	Contains factory methods to read or write ORC files.
org.apache.hadoop.hive.ql.io.orc.OrcFileKeyWrapper	Key for OrcFileMergeMapper task.
org.apache.hadoop.hive.ql.io.orc.OrcFileStripeMergeRecordReader	Record reader for orc file stripe merge.
org.apache.hadoop.hive.ql.io.orc.OrcFileValueWrapper	Value for OrcFileMergeMapper.
org.apache.hadoop.hive.ql.io.orc.OrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive.ql.io.orc.OrcNewSplit	OrcFileSplit.
org.apache.hadoop.hive.ql.io.orc.OrcRecordUpdater	A RecordUpdater where the files are stored as ORC.
org.apache.hadoop.hive.ql.io.orc.OrcSerde	A serde class for ORC.
org.apache.hadoop.hive.ql.io.orc.OrcSplit	OrcFileSplit.
org.apache.hadoop.hive.ql.io.orc.ReaderImpl	Implementation of record reader.
org.apache.hadoop.hive.ql.io.orc.VectorizedOrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive.ql.io.orc.WriterImpl	An ORC file writer.
org.apache.hadoop.hive.ql.io.parquet.LeafFilterFactory	Factory class for leaf filter.
org.apache.hadoop.hive.ql.io.parquet.MapredParquetOutputFormat	A Parquet OutputFormat for Hive (with the deprecated package mapred)
org.apache.hadoop.hive.ql.io.parquet.convert.DataWritableRecordConverter	A MapWritableReadSupport, encapsulates the tuples
org.apache.hadoop.hive.ql.io.parquet.convert.ETypeConverter.BinaryConverter	ETypeConverter is an easy way to set the converter for the right type.
org.apache.hadoop.hive.ql.io.parquet.convert.HiveCollectionConverter	Converter for collections.
org.apache.hadoop.hive.ql.io.parquet.convert.HiveGroupConverter	Converter for groups.
org.apache.hadoop.hive.ql.io.parquet.convert.HiveStructConverter	A MapWritableGroupConverter, real converter between hive and parquet types recursively for complex types.
org.apache.hadoop.hive.ql.io.parquet.read.DataWritableReadSupport	A MapWritableReadSupport Manages the translation between Hive and Parquet
org.apache.hadoop.hive.ql.io.parquet.read.ParquetRecordReaderWrapper	Wrapper for parquet record reader.
org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe	A ParquetHiveSerDe for Hive (with the deprecated package mapred)

Class	Description
org.apache.hadoop.hive.ql.io.parquet.write. DataWritableWriter	DataWritableWriter sends a record to the Parquet API with the expected schema in order to be written to a file.
org.apache.hadoop.hive.ql.io.parquet.write. ParquetRecordWriterWrapper	Wrapper for parquet record writer.
org.apache.hadoop.hive.ql.io.rcfile.stats. PartialScanMapper	PartialScanMapper.
org.apache.hadoop.hive.ql.io.rcfile.stats. PartialScanTask	PartialScanTask.
org.apache.hadoop.hive.ql.io.rcfile.stats. PartialScanWork	Partial Scan Work.
org.apache.hadoop.hive.ql.io.rcfile.truncate. ColumnTruncateMapper	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive.ql.io.rcfile.truncate. ColumnTruncateTask	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive.ql.io.sarg. SearchArgumentFactory	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive.ql.lib. DefaultGraphWalker	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive.ql.lib. RuleExactMatch	Implementation of the Rule interface for Nodes Used in Node dispatching to dispatch process/visitor functions for Nodes.
org.apache.hadoop.hive.ql.lockmgr. DbLockManager	An implementation of HiveLockManager for use with org.apache.hadoop.hive.ql.lockmgr. DbTxnManager .
org.apache.hadoop.hive.ql.lockmgr. DbTxnManager	An implementation of HiveTxnManager that stores the transactions in the metastore database.
org.apache.hadoop.hive.ql.lockmgr. HiveLockObject	The class is used to uniquely identify a HiveLockObject.
org.apache.hadoop.hive.ql.lockmgr. LockException	Exception from lock manager.
org.apache.hadoop.hive.ql.lockmgr.zookeeper. ZooKeeperHiveLock	The class is used to uniquely identify ZookeeperHiveLock.
org.apache.hadoop.hive.ql.lockmgr.zookeeper. ZooKeeperHiveLockManager	Zookeeper lock manager.
org.apache.hadoop.hive.ql.log. PerfLogger	PerfLogger.
org.apache.hadoop.hive.ql.metadata. Hive	Contains functions that implement meta data/DDDL operations using calls to the metastore.
org.apache.hadoop.hive.ql.metadata. HiveException	Generic exception class for Hive.
org.apache.hadoop.hive.ql.metadata. HiveMetaStoreChecker	Verify that the information in the metastore matches what is on the filesystem.
org.apache.hadoop.hive.ql.metadata. HiveUtils	General collection of helper functions.
org.apache.hadoop.hive.ql.metadata. Partition	A Hive Table Partition: is a fundamental storage unit within a Table.
org.apache.hadoop.hive.ql.metadata. SessionHiveMetaStoreClient	Client for hivemetastore during session.
org.apache.hadoop.hive.ql.metadata. Table	A Hive Table: is a fundamental unit of data in Hive that shares a common schema/DDDL.
org.apache.hadoop.hive.ql.metadata. VirtualColumn	Provides metadata that is not stored in table itself.
org.apache.hadoop.hive.ql.metadata.formatting. JsonMetadataFormatter	Format table and index information for machine readability using json.

Class	Description
org.apache.hadoop.hive.ql.metadata.formatting.MetadataFormatUtils	This class provides methods to format table and index information.
org.apache.hadoop.hive.ql.optimizer.BucketMapJoinOptimizer	this transformation does bucket map join optimization.
org.apache.hadoop.hive.ql.optimizer.BucketingSortingReduceSinkOptimizer	This transformation does optimization for enforcing bucketing and sorting.
org.apache.hadoop.hive.ql.optimizer.ColumnPruner	Implementation of one of the rule-based optimization steps.
org.apache.hadoop.hive.ql.optimizer.ColumnPrunerProcCtx	This class implements the processor context for Column Pruner.
org.apache.hadoop.hive.ql.optimizer.ColumnPrunerProcFactory	Factory for generating the different node processors used by ColumnPruner.
org.apache.hadoop.hive.ql.optimizer.ConstantPropagate	Implementation of one of the rule-based optimization steps.
org.apache.hadoop.hive.ql.optimizer.ConstantPropagateProcCtx	Implements the processor context for Constant Propagate.
org.apache.hadoop.hive.ql.optimizer.ConstantPropagateProcFactory	Factory for generating the different node processors used by ConstantPropagate.
org.apache.hadoop.hive.ql.optimizer.ConvertJoinMapJoin	ConvertJoinMapJoin is an optimization that replaces a common join (aka shuffle join) with a map join (aka broadcast or fragment replicate join when possible).
org.apache.hadoop.hive.ql.optimizer.GenMRProcContext	Processor Context for creating map reduce task.
org.apache.hadoop.hive.ql.optimizer.GenMapRedUtils	General utility common functions for the Processor to convert operator into map-reduce tasks.
org.apache.hadoop.hive.ql.optimizer.GlobalLimitOptimizer	This optimizer is used to reduce the input size for the query for queries which are specifying a limit.
org.apache.hadoop.hive.ql.optimizer.GroupByOptimizer	This transformation does group by optimization.
org.apache.hadoop.hive.ql.optimizer.IdentityProjectRemover	This optimization tries to remove SelectOperator from tree which don't do any processing except forwarding columns from its parent to its children.
org.apache.hadoop.hive.ql.optimizer.JoinReorder	Implementation of rule-based join table reordering optimization.
org.apache.hadoop.hive.ql.optimizer.LimitPushdownOptimizer	Make RS calculate top-K selection for limit clause.
org.apache.hadoop.hive.ql.optimizer.MapJoinProcessor	Implementation of one of the rule-based map join optimization.
org.apache.hadoop.hive.ql.optimizer.NonBlockingOpDeDupProc	Merges SEL-SEL or FIL-FIL into single operator
org.apache.hadoop.hive.ql.optimizer.ReduceSinkMapJoinProc	This processor addresses the RS-MJ case that occurs in Tez on the small/hash table. The work that RS will be a part of must be connected to the MJ work via a broadcast edge.
org.apache.hadoop.hive.ql.optimizer.SamplePruner	The transformation step that does sample pruning.
org.apache.hadoop.hive.ql.optimizer.SimpleFetchAggregation	Execute final aggregation stage for simple fetch query on fetch task.

Class	Description
org.apache.hadoop.hive.ql.optimizer. SimpleFetchOptimizer	Tries to convert simple fetch query to single fetch task, which fetches rows directly from location of table/partition.
org.apache.hadoop.hive.ql.optimizer. SkewJoinOptimizer	SkewJoinOptimizer.
org.apache.hadoop.hive.ql.optimizer. SortedDynPartitionOptimizer	When dynamic partitioning (with or without bucketing and sorting) is enabled, this optimization sorts the records on partition, bucket and sort columns respectively before inserting records into the destination table.
org.apache.hadoop.hive.ql.optimizer. SortedMergeBucketMapJoinOptimizer	Replace a bucket map join with a sorted merge map join.
org.apache.hadoop.hive.ql.optimizer. StatsOptimizer	There is a set of queries which can be answered entirely from statistics stored in metastore.
org.apache.hadoop.hive.ql.optimizer. Transform	Optimizer interface.
org.apache.hadoop.hive.ql.optimizer.calcite. HiveCalciteUtil	Generic utility functions needed for Calcite based Hive CBO.
org.apache.hadoop.hive.ql.optimizer.calcite. HiveRelOptUtil	Splits different join conditions.
org.apache.hadoop.hive.ql.optimizer.calcite. RelOptHiveTable	Class for handling all table metadata.
org.apache.hadoop.hive.ql.optimizer.calcite. TraitsUtil	Traits utilities.
org.apache.hadoop.hive.ql.optimizer.calcite.cost. HiveRelMdCost	HiveRelMdCost supplies the implementation of cost model.
org.apache.hadoop.hive.ql.optimizer.calcite.cost. HiveVolcanoPlanner	Refinement of org.apache.calcite.plan.volcano.VolcanoPlanner for Hive.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveAggregate	Describing aggregate function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveFilter	Describing filter function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveJoin	Describing join function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveProject	Creates a HiveProject.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveSemiJoin	Describing semi join operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveTableScan	Relational expression representing a scan of a HiveDB collection.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveUnion	Describing union operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveFilterJoinRule	Creates a PushFilterPastJoinRule with an explicit root operand.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveJoinProjectTransposeRule	Transpose rule for hive join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveFilterSetOpTransposeRule	Creates a HiveFilterSetOpTransposeRule.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveInsertExchange4JoinRule	Not an optimization rule.

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinAddNotNullRule	Creates an HiveJoinAddNotNullRule.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinPushTransitivePredicatesRule	Planner rule that infers predicates from on a org.apache.calcite.rel.core.Join and creates org.apache.calcite.rel.core.Filters if those predicates can be pushed to its inputs.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinToMultiJoinRule	Rule that merges a join with multijoin/join children if the equi compared the same set of input columns.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HivePreFilteringRule	Pull out deterministic expressions from non-deterministic and push down deterministic expressions as a separate filter.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectMergeRule	ProjectMergeRule merges a org.apache.calcite.rel.core.Project into another org.apache.calcite.rel.core.Project, provided the projects aren't projecting identical sets of input references.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveRelFieldTrimmer	Hive relational expression field trimmer.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdCollation	Hive relational expression metadata collation.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdDistinctRowCount	Hive relational expression metadata.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdDistribution	Hive relational expression metadata distribuiton.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdMemory	Hive relational expression metadata memory
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdParallelism	Hive relational expression metadata parallelism.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdRowCount	Hive relational expression metadata row count.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdSelectivity	Hive relational expression metadata selectivity.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdSize	Hive relational expression metadata size.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdUniqueKeys	Hive relational expression metadata unique keys.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.ASTConverter	Abstract syntax tree converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.ExpressionNodeConverter	Expression node converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.HiveOpConverter	Hive operation converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.HiveOpConverterPostProc	Post processing hive operation converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.PlanModifierForASTConv	Modifying plan for converting abstract syntax tree.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.PlanModifierForReturnPath	Modifying plan for operation tree.

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.translator.RexNodeConverter	Row expression node converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.SqlFunctionConverter	Converting SQL function.
org.apache.hadoop.hive.ql.optimizer.correlation.CorrelationOptimizer	Implementation of Correlation Optimizer.
org.apache.hadoop.hive.ql.optimizer.correlation.CorrelationUtilities	Utilities for both CorrelationOptimizer and ReduceSinkDeDuplication.
org.apache.hadoop.hive.ql.optimizer.correlation.ReduceSinkDeDuplication	If two reducer sink operators share the same partition/sort columns and order, they can be merged.
org.apache.hadoop.hive.ql.optimizer.index.RewriteGBUsingIndex	RewriteGBUsingIndex is implemented as one of the Rule-based Optimizations.
org.apache.hadoop.hive.ql.optimizer.index.RewriteParseContextGenerator	RewriteParseContextGenerator is a class that offers methods to generate operator tree for input queries.
org.apache.hadoop.hive.ql.optimizer.lineage.ExprProcFactory	Expression processor factory for lineage.
org.apache.hadoop.hive.ql.optimizer.lineage.Generator	Generates the lineage information for the columns and tables from the plan before it goes through other optimization phases.
org.apache.hadoop.hive.ql.optimizer.lineage.LineageCtx	Contains the lineage context that is passed while walking the operator tree in Lineage.
org.apache.hadoop.hive.ql.optimizer.lineage.OpProcFactory	Operator factory for the rule processors for lineage.
org.apache.hadoop.hive.ql.optimizer.listbucketingpruner.ListBucketingPruner	The transformation step that does list bucketing pruning.
org.apache.hadoop.hive.ql.optimizer.metainfo.annotation.AnnotateWithOpTraits	This class annotates each operator with its traits. The OpTraits class specifies the traits that are populated for each operator.
org.apache.hadoop.hive.ql.optimizer.pcr.PartitionConditionRemover	The transformation step that does partition condition remover.
org.apache.hadoop.hive.ql.optimizer.pcr.PcrExprProcFactory	Expression processor factory for partition condition removing.
org.apache.hadoop.hive.ql.optimizer.physical.CrossProductCheck	Check each MapJoin and ShuffleJoin Operator to see they are performing a cross product.
org.apache.hadoop.hive.ql.optimizer.physical.Vectorizer	Class to define vectorization.
org.apache.hadoop.hive.ql.optimizer.ppr.PartitionExpressionProxyForMetastore	The basic implementation of PartitionExpressionProxy that uses ql package classes.
org.apache.hadoop.hive.ql.optimizer.ppr.PartitionPruner	The transformation step that does partition pruning.
org.apache.hadoop.hive.ql.optimizer.spark.SparkReduceSinkMapJoinProc	This processor addresses the RS-MJ case that occurs in spark on the small/hash table side of things. The work that RS will be a part of must be connected to the MJ work via be a broadcast edge.
org.apache.hadoop.hive.ql.optimizer.stats.annotation.AnnotateWithStatistics	Create a list of top op nodes
org.apache.hadoop.hive.ql.optimizer.unionproc.UnionProcessor	FileSinkProcessor is a simple rule to remember seen unions for later processing.
org.apache.hadoop.hive.ql.parse.ASTNode	Definition of abstract syntax tree node.

Class	Description
org.apache.hadoop.hive.ql.parse.BaseSemanticAnalyzer	BaseSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.CalcitePlanner	Cost based optimizer planner.
org.apache.hadoop.hive.ql.parse.ColumnAccessAnalyzer	Analysis of column access.
org.apache.hadoop.hive.ql.parse.ColumnStatsSemanticAnalyzer	ColumnStatsSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.DDLSemanticAnalyzer	DDLSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExplainSQRewriteSemanticAnalyzer	ExplainSQRewriteSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExplainSemanticAnalyzer	ExplainSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExportSemanticAnalyzer	ExportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.FunctionSemanticAnalyzer	FunctionSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.GenTezProcContext	GenTezProcContext.
org.apache.hadoop.hive.ql.parse.GenTezUtils	GenTezUtils is a collection of shared helper methods to produce TezWork.
org.apache.hadoop.hive.ql.parse.GlobalLimitCtx	context for pruning inputs.
org.apache.hadoop.hive.ql.parse.ImportSemanticAnalyzer	ImportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.LoadSemanticAnalyzer	LoadSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.MacroSemanticAnalyzer	MacroSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.MapReduceCompiler	Compiling list of tasks.
org.apache.hadoop.hive.ql.parse.MetadataExportListener	Listens for drop events and, if set, exports the table's metadata as JSON to the trash of the user performing the drop
org.apache.hadoop.hive.ql.parse.ParseContext	Parse Context: The current parse context.
org.apache.hadoop.hive.ql.parse.ParseDriver	ParseDriver.
org.apache.hadoop.hive.ql.parse.ParseUtils	Library of utility functions used in the parse code.
org.apache.hadoop.hive.ql.parse.QB	Implementation of the query block.
org.apache.hadoop.hive.ql.parse.QBParseInfo	Implementation of the parse information related to a query block.
org.apache.hadoop.hive.ql.parse.RowResolver	Implementation of the Row Resolver.
org.apache.hadoop.hive.ql.parse.SemanticAnalyzer	Implementation of the semantic analyzer.
org.apache.hadoop.hive.ql.parse.SemanticAnalyzerFactory	SemanticAnalyzerFactory.
org.apache.hadoop.hive.ql.parse.SplitSample	Stores all the information specified in the TABLESAMPLE(...) clause.
org.apache.hadoop.hive.ql.parse.TaskCompiler	TaskCompiler is a the base class for classes that compile operator pipelines into tasks.
org.apache.hadoop.hive.ql.parse.TezCompiler	TezCompiler translates the operator plan into TezTasks.

Class	Description
org.apache.hadoop.hive.ql.parse.TypeCheckCtx	This class implements the context information that is used for typechecking phase in query compilation.
org.apache.hadoop.hive.ql.parse.TypeCheckProcFactory	The Factory for creating typecheck processors.
org.apache.hadoop.hive.ql.parse.UpdateDeleteSemanticAnalyzer	A subclass of the org.apache.hadoop.hive.ql.parse.SemanticAnalyzer that just handles update and delete statements.
org.apache.hadoop.hive.ql.parse.WindowingSpec	Windowing Specification.
org.apache.hadoop.hive.ql.parse.spark.GenSparkProcContext	GenSparkProcContext maintains information about the tasks and operators as we walk the operator tree to break them into SparkTasks.
org.apache.hadoop.hive.ql.parse.spark.GenSparkUtils	GenSparkUtils is a collection of shared helper methods to produce SparkWork Cloned from GenTezUtils.
org.apache.hadoop.hive.ql.parse.spark.GenSparkWorkWalker	Walks the operator tree in DFS fashion.
org.apache.hadoop.hive.ql.parse.spark.OptimizeSparkProcContext	OptimizeSparkProcContext.
org.apache.hadoop.hive.ql.plan.AbstractOperatorDesc	Operator description.
org.apache.hadoop.hive.ql.plan.AlterTableDesc	AlterTableDesc.
org.apache.hadoop.hive.ql.plan.AlterTableSimpleDesc	Contains information needed to modify a partition or a table
org.apache.hadoop.hive.ql.plan.BaseWork	BaseWork.
org.apache.hadoop.hive.ql.plan.ColumnStatsDesc	Contains the information needed to persist column level statistics
org.apache.hadoop.hive.ql.plan.ColumnStatsWork	ColumnStats Work.
org.apache.hadoop.hive.ql.plan.CommonMergeJoinDesc	Description of merge join operator.
org.apache.hadoop.hive.ql.plan.CreateTableDesc	CreateTableDesc.
org.apache.hadoop.hive.ql.plan.CreateViewDesc	CreateViewDesc.
org.apache.hadoop.hive.ql.plan.DDLWork	DDLWork.
org.apache.hadoop.hive.ql.plan.DropTableDesc	DropTableDesc.
org.apache.hadoop.hive.ql.plan.DynamicPartitionCtx	Dynamic partition context.
org.apache.hadoop.hive.ql.plan.DynamicPruningEventDesc	Dynamic pruning event description.
org.apache.hadoop.hive.ql.plan.ExplainWork	ExplainWork.
org.apache.hadoop.hive.ql.plan.ExprNodeDesc	ExprNodeDesc.
org.apache.hadoop.hive.ql.plan.ExprNodeDescUtils	Utilities for expression node description.
org.apache.hadoop.hive.ql.plan.FetchWork	FetchWork.
org.apache.hadoop.hive.ql.plan.FileSinkDesc	FileSinkDesc.
org.apache.hadoop.hive.ql.plan.FilterDesc	FilterDesc.
org.apache.hadoop.hive.ql.plan.GroupByDesc	GroupByDesc.
org.apache.hadoop.hive.ql.plan.HashTableSinkDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan.JoinCondDesc	Join conditions Descriptor implementation.

Class	Description
org.apache.hadoop.hive.ql.plan. JoinDesc	Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. LateralViewJoinDesc	LateralViewJoinDesc.
org.apache.hadoop.hive.ql.plan. LimitDesc	LimitDesc.
org.apache.hadoop.hive.ql.plan. LoadTableDesc	LoadTableDesc.
org.apache.hadoop.hive.ql.plan. MapJoinDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. MapWork	MapWork represents all the information used to run a map task on the cluster.
org.apache.hadoop.hive.ql.plan. MapredWork	MapredWork.
org.apache.hadoop.hive.ql.plan. MergeJoinWork	Creating merge join work.
org.apache.hadoop.hive.ql.plan. PartitionDesc	PartitionDesc.
org.apache.hadoop.hive.ql.plan. PlanUtils	PlanUtils.
org.apache.hadoop.hive.ql.plan. ReduceSinkDesc	ReduceSinkDesc.
org.apache.hadoop.hive.ql.plan. ReduceWork	ReduceWork represents all the information used to run a reduce task on the cluster.
org.apache.hadoop.hive.ql.plan. SelectDesc	SelectDesc.
org.apache.hadoop.hive.ql.plan. SparkHashTableSinkDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. Statistics	Statistics.
org.apache.hadoop.hive.ql.plan. StatsWork	ConditionalStats.
org.apache.hadoop.hive.ql.plan. TableScanDesc	Table Scan Descriptor Currently, data is only read from a base source as part of map-reduce framework.
org.apache.hadoop.hive.ql.plan. TezWork	TezWork.
org.apache.hadoop.hive.ql.plan. UnionWork	Simple wrapper for union all cases.
org.apache.hadoop.hive.ql.plan. VectorGroupByDesc	VectorGroupByDesc.
org.apache.hadoop.hive.ql.plan.ptf. BoundaryDef	Map-reduce boundaries definition.
org.apache.hadoop.hive.ql.plan.ptf. CurrentRowDef	Current row definition.
org.apache.hadoop.hive.ql.plan.ptf. OrderExpressionDef	Order expression definition.
org.apache.hadoop.hive.ql.plan.ptf. RangeBoundaryDef	Range boundary definition.
org.apache.hadoop.hive.ql.plan.ptf. ValueBoundaryDef	Value boundary definition.
org.apache.hadoop.hive.ql.plan.ptf. WindowFrameDef	Window frame definition.
org.apache.hadoop.hive.ql.ppd. ExprWalkerInfo	Context for Expression Walker for determining predicate pushdown candidates It contains a ExprInfo object for each expression that is processed.
org.apache.hadoop.hive.ql.ppd. OpProcFactory	Operator factory for predicate pushdown processing of operator graph Each operator determines the pushdown predicates by walking the expression tree.
org.apache.hadoop.hive.ql.ppd. PredicatePushDown	Implements predicate pushdown.
org.apache.hadoop.hive.ql.ppd. PredicateTransitivePropagate	Propagates filters to other aliases based on join condition
org.apache.hadoop.hive.ql.ppd. SyntheticJoinPredicate	Creates synthetic predicates that represent "IN (keylist other table)"

Class	Description
org.apache.hadoop.hive.ql.processors. AddResourceProcessor	AddResourceProcessor.
org.apache.hadoop.hive.ql.processors. CommandProcessorResponse	Encapsulates the basic response info returned by classes the implement the CommandProcessor interface.
org.apache.hadoop.hive.ql.processors. CompileProcessor	Processor allows users to build code inside a hive session, then use this code as a UDF, Serde, or even a more complex entity like an input format or hook.
org.apache.hadoop.hive.ql.processors. CryptoProcessor	Processes HADOOP commands used for HDFS encryption.
org.apache.hadoop.hive.ql.processors. DeleteResourceProcessor	DeleteResourceProcessor.
org.apache.hadoop.hive.ql.processors. DfsProcessor	DfsProcessor.
org.apache.hadoop.hive.ql.processors. SetProcessor	SetProcessor.
org.apache.hadoop.hive.ql.security.authorization. AuthorizationPreEventListener	AuthorizationPreEventListener : A MetaStorePreEventListener that performs authorization/authentication checks on the metastore-side.
org.apache.hadoop.hive.ql.security.authorization. AuthorizationUtils	Utility code shared by hive internal code and sql standard authorization plugin implementation
org.apache.hadoop.hive.ql.security.authorization. HiveAuthorizationProviderBase	Class for authorization that returns userNames and groupNames.
org.apache.hadoop.hive.ql.security.authorization.plugin. AuthorizationMetaStoreFilterHook	Metastore filter hook for filtering out the list of objects that the current authorization implementation does not allow user to see
org.apache.hadoop.hive.ql.security.authorization.plugin. HiveAuthorizerImpl	Convenience implementation of HiveAuthorizer.
org.apache.hadoop.hive.ql.security.authorization.plugin. HiveAuthzContext	Provides context information in authorization check call that can be used for auditing and/or authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin. HivePrivilegeObject	Represents the object on which privilege is being granted/revoked, and objects being used in queries.
org.apache.hadoop.hive.ql.security.authorization.plugin. HiveV1Authorizer	Hive v1 authorization class.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. DummyHiveAuthorizationValidator	A no-op HiveAuthorizationValidator for use from hive cli.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. SQLAuthorizationUtils	Utilities for SQL based authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. SQLStdHiveAccessController	Implements functionality of access control statements for sql standard based authorization
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. SQLStdHiveAuthorizationValidator	Class to check if user has privileges to perform certain action according to SQL standart hive authorization.
org.apache.hadoop.hive.ql.session. LineageState	LineageState.
org.apache.hadoop.hive.ql.session. OperationLog	OperationLog wraps the actual operation log file, and provides interface for accessing, reading, writing, and removing the file.
org.apache.hadoop.hive.ql.session. SessionState	SessionState encapsulates common data associated with a session.

Class	Description
org.apache.hadoop.hive.ql.stats. StatsFactory	A factory of stats publisher and aggregator implementations of the StatsPublisher and StatsAggregator interfaces.
org.apache.hadoop.hive.ql.stats. StatsUtils	Utilities of stats publisher and aggregator.
org.apache.hadoop.hive.ql.stats.fs. FSSStatsAggregator	File system stats aggregator.
org.apache.hadoop.hive.ql.stats.fs. FSSStatsPublisher	File system stats publisher.
org.apache.hadoop.hive.ql.txn.compactor. CompactorMR	Performs compactions via an MR job.
org.apache.hadoop.hive.ql.txn.compactor. Worker	Performs compactions.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFAverage	GenericUDFAverage.
org.apache.hadoop.hive.ql.udf.generic. GenericUDAFStreamingEvaluator	User defined aggregate function streaming evaluator.
org.apache.hadoop.hive.ql.udf.generic. GenericUDAFSum	GenericUDAFSum.
org.apache.hadoop.hive.ql.udf.generic. GenericUDF	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFBasePad	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFBridge	GenericUDFBridge encapsulates UDF to provide the same interface as GenericUDF.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFDateAdd	UDFDateAdd.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFDateSub	UDFDateSub.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFFromUtcTimestamp	Generic user defined function to compute UTC timestamp.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFGreatest	GenericUDF Class for SQL construct "greatest(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic. GenericUDFLeast	GenericUDF Class for SQL construct "least(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic. GenericUDFLpad	UDFLpad.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPAnd	GenericUDF Class for computing and.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPEqual	GenericUDF Class for operation EQUAL.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPEqualOrGreaterThan	GenericUDF Class for operation EqualOrGreaterThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPEqualOrLessThan	GenericUDF Class for operation EqualOrLessThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPGreaterThan	GenericUDF Class for operation GreaterThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPLessThan	GenericUDF Class for operation LessThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPNotEqual	GenericUDF Class for operation Not EQUAL.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPNotNull	GenericUDFOPNotNull.

Class	Description
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPNull	GenericUDFOPNull.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPor	GenericUDF Class for computing or.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFRound	Rounding function permits rounding off integer digits in decimal numbers, which essentially downgrades the scale to negative territory.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFRpad	UDFRpad.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFToUnixTimeStamp	Deterministic version of UDFUnixTimeStamp.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFUtils	Util functions for GenericUDF classes.
org.apache.hadoop.hive.ql.udf.generic. NumDistinctValueEstimator	Take the average of the index for all the bit vectors and get the estimated NDV (estimateNumDistinctValues).
org.apache.hadoop.hive.ql.udf.generic. NumericHistogram	A generic, re-usable histogram class that supports partial aggregations.
org.apache.hadoop.hive.ql.udf.generic. RoundUtils	Utility class for generic round UDF.
org.apache.hadoop.hive.ql.udf.ptf. WindowingTableFunction	A window function performs a calculation across a set of table rows that are somehow related to the current row.
org.apache.hadoop.hive.ql.util. DateTimeMath	Operations involving/returning year-month intervals.
org.apache.hadoop.hive.ql.util. DosToUnix	Converting windows script to UNIX.
org.apache.hadoop.hive.ql.util. ZooKeeperHiveHelper	Get the ensemble server addresses from the configuration. The format is: host1:port,host2:port
org.apache.hadoop.hive.serde2. AbstractSerDe	Abstract class for implementing SerDe.
org.apache.hadoop.hive.serde2. ColumnProjectionUtils	ColumnProjectionUtils.
org.apache.hadoop.hive.serde2. DelimitedJSONSerDe	DelimitedJSONSerDe.
org.apache.hadoop.hive.serde2. MetadataTypedColumnsetSerDe	MetadataTypedColumnsetSerDe.
org.apache.hadoop.hive.serde2. OpenCSVSerde	OpenCSVSerde use opencsv to deserialize CSV format.
org.apache.hadoop.hive.serde2. RegexSerDe	RegexSerDe uses regular expression (regex) to deserialize data.
org.apache.hadoop.hive.serde2. SerDeUtils	SerDeUtils.
org.apache.hadoop.hive.serde2. WriteBuffers	The structure storing arbitrary amount of data as a set of fixed-size byte buffers.
org.apache.hadoop.hive.serde2.avro. AvroLazyObjectInspector	Lazy objectinspector for avro serialization
org.apache.hadoop.hive.serde2.avro. AvroSerDe	Read or write Avro data from Hive.
org.apache.hadoop.hive.serde2.avro. AvroSerdeUtils	Utilities useful only to the AvroSerde itself.
org.apache.hadoop.hive.serde2.binarysortable. BinarySortableSerDe	BinarySortableSerDe can be used to write data in a way that the data can be compared byte-by-byte with the same order.
org.apache.hadoop.hive.serde2.binarysortable.fast. BinarySortableDeserializeRead	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.binarysortable.fast. BinarySortableSerializeWrite	Directly serialize, field-by-field, the BinarySortable format.

Class	Description
org.apache.hadoop.hive.serde2.io. DateWritable	DateWritable Writable equivalent of java.sql.Date.
org.apache.hadoop.hive.serde2.io. HiveDecimalWritable	Get a HiveDecimal instance from the writable and constraint it with maximum precision/scale.
org.apache.hadoop.hive.serde2.io. TimestampWritable	TimestampWritable Writable equivalent of java.sql.Timestamp Timestamps are of the format YYYY-MM-DD HH:MM:SS.[fff...] We encode Unix timestamp in seconds in 4 bytes, using the MSB to signify whether the timestamp has a fractional portion.
org.apache.hadoop.hive.serde2.lazy. LazyBinary	LazyBinary stores a binary object in a LazyObject.
org.apache.hadoop.hive.serde2.lazy. LazyHiveDecimal	LazyHiveDecimal stores hive decimal object in LazyObject.
org.apache.hadoop.hive.serde2.lazy. LazyMap	LazyMap stores a map of Primitive LazyObjects to LazyObjects.
org.apache.hadoop.hive.serde2.lazy. LazySerDeParameters	SerDeParameters.
org.apache.hadoop.hive.serde2.lazy. LazySimpleSerDe	LazySimpleSerDe can be used to read the same data format as MetadataTypedColumnsetSerDe and TCTLSeparatedProtocol.
org.apache.hadoop.hive.serde2.lazy. LazyUtils	LazyUtils.
org.apache.hadoop.hive.serde2.lazy.fast. LazySimpleDeserializeRead	Directly deserialize with the caller reading field-by-field the LazySimple (text) serialization format.
org.apache.hadoop.hive.serde2.lazy.fast. LazySimpleSerializeWrite	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.lazy.objectinspector. LazyListObjectInspector	LazyListObjectInspector works on array data that is stored in LazyArray.
org.apache.hadoop.hive.serde2.lazy.objectinspector. LazyMapObjectInspector	LazyMapObjectInspector works on struct data that is stored in LazyStruct.
org.apache.hadoop.hive.serde2.lazy.objectinspector. LazyUnionObjectInspector	LazyUnionObjectInspector works on union data that is stored in LazyUnion.
org.apache.hadoop.hive.serde2.lazybinary. LazyBinarySerDe	The LazyBinarySerDe class combines the lazy property of LazySimpleSerDe class and the binary property of BinarySortable class.
org.apache.hadoop.hive.serde2.lazybinary.fast. LazyBinaryDeserializeRead	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.lazybinary.fast. LazyBinarySerializeWrite	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.objectinspector. ObjectInspectorFactory	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector. ObjectInspectorUtils	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector. ReflectionStructObjectInspector	ReflectionStructObjectInspector works on struct data that is stored as a native Java object.
org.apache.hadoop.hive.serde2.objectinspector. SettableUnionObjectInspector	SettableUnionObjectInspector.
org.apache.hadoop.hive.serde2.objectinspector. StandardStructObjectInspector	ListStructObjectInspector works on struct data that is stored as a Java List or Java Array object.

Class	Description
org.apache.hadoop.hive.serde2.objectinspector. StandardUnionObjectInspector	StandardUnionObjectInspector works on union data that is stored as UnionObject.
org.apache.hadoop.hive.serde2.objectinspector. ThriftUnionObjectInspector	Always use the ObjectInspectorFactory to create new ObjectInspector objects, instead of directly creating an instance of this class.
org.apache.hadoop.hive.serde2.typeinfo. HiveDecimalUtils	Utilities for decimal precision and scale.
org.apache.hadoop.hive.serde2.typeinfo. TypeInfoUtils	TypeInfoUtils.
org.apache.hadoop.hive.shims. Hadoop23Shims	Implementation of shims against Hadoop 0.23.0.
org.apache.hadoop.hive.shims. HadoopShimsSecure	Base implementation for shims against secure Hadoop 0.20.3/0.23.
org.apache.hadoop.hive.shims. ShimLoader	ShimLoader.
org.apache.hadoop.hive.shims. Utils	Utilities for split location provider.
org.apache.hadoop.hive.thrift. DelegationTokenSecretManager	A Hive specific delegation token secret manager.
org.apache.hadoop.hive.thrift. HadoopThriftAuthBridge	Functions that bridge Thrift's SASL transports to Hadoop's SASL callback handlers and authentication classes.
org.apache.hadoop.hive.thrift. TokenStoreDelegationTokenSecretManager	Extension of DelegationTokenSecretManager to support alternative to default in-memory token management for fail-over and clustering through plug-able token store (ZooKeeper etc.).
org.apache.hive.beeline. BeeLine	A console SQL shell with command completion.
org.apache.hive.beeline. Commands	Implementation of beeline commands.
org.apache.hive.common.util. BloomFilter	BloomFilter is a probabilistic data structure for set membership check.
org.apache.hive.common.util. DateUtils	DateUtils.
org.apache.hive.common.util. HiveStringUtils	HiveStringUtils General string utils Originally copied from o.a.hadoop.util.StringUtils
org.apache.hive.common.util. HiveTestUtils	Utilities for testing hive.
org.apache.hive.common.util. Murmur3	Murmur3 is successor to Murmur2 fast non-cryptographic hash algorithms.
org.apache.hive.common.util. ShutdownHookManager	The ShutdownHookManager enables running shutdownHook in a deterministic order, higher priority first.
org.apache.hive.common.util. StreamPrinter	StreamPrinter.
org.apache.hive.hcatalog.cli. HCatCli	HCatalog command line interface.
org.apache.hive.hcatalog.common. HCatConstants	List of constants used by HCatalog.
org.apache.hive.hcatalog.streaming. ConnectionError	Exception to catch connection errors.
org.apache.hive.hcatalog.streaming. DelimitedInputWriter	Streaming Writer handles delimited input (eg.
org.apache.hive.hcatalog.streaming. HiveEndPoint	Information about the hive end point (i.e.
org.apache.hive.hcatalog.streaming. InvalidTable	Exception to catch invalid table.
org.apache.hive.hcatalog.streaming. StrictJsonWriter	Streaming Writer handles utf8 encoded Json (Strict syntax).

Class	Description
org.apache.hive.hcatalog.templeton. AppConfig	The configuration for Templeton.
org.apache.hive.hcatalog.templeton. Main	The main executable that starts up and runs the Server.
org.apache.hive.jdbc .HiveConnection	HiveConnection.
org.apache.hive.jdbc .HiveDatabaseMetaData	HiveDatabaseMetaData.
org.apache.hive.jdbc .HivePreparedStatement	HivePreparedStatement.
org.apache.hive.jdbc .HiveQueryResultSet	HiveQueryResultSet.
org.apache.hive.jdbc .HiveStatement	HiveStatement.
org.apache.hive.jdbc .JdbcColumn	Column metadata.
org.apache.hive.jdbc .Utils	Utilities for jdbc.
org.apache.hive.service. ServiceUtils	Utilities to correctly process domain names etc.
org.apache.hive.service.auth. AuthenticationProviderFactory	Helps select a PasswdAuthenticationProvider for a given {@code AuthMethod}.
org.apache.hive.service.auth. HiveAuthFactory	Helps in some aspects of authentication.
org.apache.hive.service.auth. LdapAuthenticationProviderImpl	Utilities to correctly process domain names etc.
org.apache.hive.service.auth. TSetupAddressProcessor	Sets the ipAddress for operations executed via HiveServer2.
org.apache.hive.service.cli. CLIService	CLIService.
org.apache.hive.service.cli. CLIServiceUtils	CLIServiceUtils.
org.apache.hive.service.cli. ColumnBasedSet	ColumnBasedSet.
org.apache.hive.service.cli. ColumnDescriptor	ColumnDescriptor.
org.apache.hive.service.cli. ColumnValue	Protocols before HIVE_CLI_SERVICE_PROTOCOL_V6 (used by RowBasedSet)
org.apache.hive.service.cli. EmbeddedCLIServiceClient	Embedded CLI Service Client.
org.apache.hive.service.cli. FetchOrientation	Fetch Orientation.
org.apache.hive.service.cli. GetInfoType	Get Info type.
org.apache.hive.service.cli. GetInfoValue	Get Info value.
org.apache.hive.service.cli. Handle	Handle.
org.apache.hive.service.cli. HandleIdentifier	Handle identifier.
org.apache.hive.service.cli. HiveSQLException	Hive SQL exception.

Class	Description
org.apache.hive.service.cli. OperationHandle	Handler for operation.
org.apache.hive.service.cli. OperationState	Operation State.
org.apache.hive.service.cli. OperationStatus	Operation Status.
org.apache.hive.service.cli. OperationType	OperationType.
org.apache.hive.service.cli. RowBasedSet	Row Based Set.
org.apache.hive.service.cli. RowSetFactory	Row set factory class.
org.apache.hive.service.cli. SessionHandle	Session Handle.
org.apache.hive.service.cli. TableSchema	Table Schema.
org.apache.hive.service.cli. TypeDescriptor	Type Descriptor.
org.apache.hive.service.cli. TypeQualifiers	Holds type qualifier information for a primitive type, such as char/varchar length or decimal precision/scale.
org.apache.hive.service.cli.operation. ClassicTableTypeMapping	Classic Table Type Mapping.
org.apache.hive.service.cli.operation. ExecuteStatementOperation	Implementation of statement execution.
org.apache.hive.service.cli.operation. HiveCommandOperation	Executes a HiveCommand.
org.apache.hive.service.cli.operation. HiveTableTypeMapping	Hive Table Type Mapping.
org.apache.hive.service.cli.operation. LogDivertAppender	Divert appender to redirect operation logs to separate files.
org.apache.hive.service.cli.operation. MetadataOperation	Metadata Operation.
org.apache.hive.service.cli.operation. Operation	Class to define operation.
org.apache.hive.service.cli.operation. OperationManager	Operation Manager.
org.apache.hive.service.cli.operation. SQLOperation	SQL Operation.
org.apache.hive.service.cli.session. HiveSessionImpl	Hive Session.
org.apache.hive.service.cli.session. HiveSessionImplwithUGI	Hive session implementation with UGI.
org.apache.hive.service.cli.session. SessionManager	Session Manager.
org.apache.hive.service.cli.thrift. ThriftBinaryCLIService	Initialize worker threads in hive CLI startup.
org.apache.hive.service.cli.thrift. ThriftCLIService	Thrift CLI Service.
org.apache.hive.service.cli.thrift. ThriftCLIServiceClient	Thrift CLI Service Client.
org.apache.hive.service.cli.thrift. ThriftHttpCLIService	Service to handle requests over HTTP.
org.apache.hive.service.cli.thrift. ThriftHttpServlet	Thrift Http servlet.
org.apache.hive.spark.client. MetricsCollection	Provides metrics collected for a submitted job.
org.apache.hive.spark.client. SparkClientUtilities	Utilities for spark client.
org.apache.hive.spark.client.rpc. Rpc	Encapsulates the RPC functionality.
org.apache.hive.spark.client.rpc. RpcConfiguration	Definitions of configuration keys and default values for the RPC layer.
org.apache.hive.spark.client.rpc. RpcServer	An RPC server.

Changed Interfaces in Hive 2.1

The following interfaces have changed in Hive 2.1:

Interface	Description
org.apache.hadoop.hive.common. ValidTxnList	Models the list of transactions that should be included in a snapshot.
org.apache.hadoop.hive.metastore. AlterHandler	Interface for Alter Table and Alter Partition code
org.apache.hadoop.hive.metastore. IMetaStoreClient	Wrapper around hive metastore thrift api
org.apache.hadoop.hive.metastore. RawStore	
org.apache.hadoop.hive.metastore. PartitionExpressionProxy	The proxy interface that metastore uses for variety of QL operations (metastore can't depend on QL because QL depends on metastore; creating metastore-client module would be a proper way to solve this problem).
org.apache.hadoop.hive ql.exec.persistence. MapJoinTableContainer	
org.apache.hadoop.hive ql.exec.spark. SparkShuffler	
org.apache.hadoop.hive ql.exec.spark. SparkTran	
org.apache.hadoop.hive ql.exec.spark.session. SparkSession	
org.apache.hadoop.hive ql.exec.spark.status. SparkJobStatus	SparkJobStatus identify what Hive want to know about the status of a Spark job.
org.apache.hadoop.hive ql.exec.vector.expressions. VectorExpressionWriter	Interface used to create Writable objects from vector expression primitives.
org.apache.hadoop.hive ql.exec.vector.mapjoin.hashtable. VectorMapJoinHashTable	
org.apache.hadoop.hive ql.io. InputFormatChecker	Check for validity of the input files.
org.apache.hadoop.hive ql.io.orc. Reader	The interface for reading ORC files.
org.apache.hadoop.hive ql.io.orc. RecordReader	A row-by-row iterator for ORC files.
org.apache.hadoop.hive ql.io.orc. Writer	The HIVE interface for writing ORC files.
org.apache.hadoop.hive ql.io.sarg. SearchArgument	Primary interface for SearchArgument , which are the subset of predicates that can be pushed down to the RecordReader.
org.apache.hadoop.hive ql.lockmgr. HiveTxnManager	An interface that allows Hive to manage transactions.
org.apache.hadoop.hive ql.metadata.formatting. MetaDateFormatter	Interface to format table and index information.
org.apache.hadoop.hive ql.plan. OperatorDesc	
org.apache.hadoop.hive ql.security.authorization.plugin. HiveAuthorizationValidator	Interface used to check if user has privileges to perform certain action.
org.apache.hadoop.hive ql.security.authorization.plugin. HiveAuthorizer	Interface for hive authorization plugins.
org.apache.hadoop.hive ql.stats. StatsAggregator	An interface for any possible implementation for gathering statistics.
org.apache.hadoop.hive ql.stats. StatsPublisher	An interface for any possible implementation for publishing statics.

Interface	Description
org.apache.hadoop.hive.shims. HadoopShims	In order to be compatible with multiple versions of Hadoop, all parts of the Hadoop interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hive.hcatalog.streaming. StreamingConnection	Represents a connection to a HiveEndPoint.
org.apache.hive.hcatalog.streaming. TransactionBatch	Represents a set of Transactions returned by Hive.
org.apache.hive.service.cli. ICLIService	
org.apache.hive.service.cli. RowSet	
org.apache.hive.service.cli.operation. TableTypeMapping	
org.apache.hive.service.cli.session. HiveSession	
org.apache.hive.service.cli.session. HiveSessionBase	Methods that don't need to be executed under a doAs context are here.
org.apache.hive.spark.client. JobContext	Holds runtime information about the job execution context.
org.apache.hive.spark.client. SparkClient	Defines the API for the Spark remote client.

Removed API in Hive 2.1

The following classes and interfaces are not available with Hive 2.1:

Removed Classes

Class	Description
org.apache.hadoop.hive.common.metrics.Metrics	Metrics Subsystem - allows exposure of a number of named parameters/counters via jmx, intended to be used as a static subsystem Has a couple of primary ways it can be used: (i) Using the set and get methods to set and get named parameters (ii) Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set.
org.apache.hadoop.hive.hbase.HBaseStatsAggregator	A class that implements the StatsAggregator interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsPublisher	A class that implements the StatsPublisher interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsSetupConstants	HBase constants statistics setup.
org.apache.hadoop.hive.hbase.HBaseStatsUtils	Utilities for hbase statistics.
org.apache.hadoop.hive.metastore.ProtectMode	Protection Mode.
org.apache.hadoop.hive.metastore.txn.CompactionTxnHandler	Extends the transaction handler with methods needed only by the compactor threads.
org.apache.hadoop.hive.metastore.txn.TxnHandler	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive.metastore.txn.ValidCompactorTxnList	And implmentation of org.apache.hadoop.hive.common.ValidTxnList for use by the compactor.
org.apache.hadoop.hive.ql.exec.DefaultFetchFormatter	Serializes row by user specified serde and call toString() to make string type result

Class	Description
org.apache.hadoop.hive.ql.exec.Heartbeater	Class to handle heartbeats for MR and Tez tasks.
org.apache.hadoop.hive.ql.exec.vector.RandomRowObjectSource	Generates object inspector and random row object[].
org.apache.hadoop.hive.ql.exec.vector.VectorAssignRowDynBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive.ql.exec.vector.VectorAssignRowSameBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive.ql.exec.vector.VectorSerializeRowNoNulls	Serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive.ql.exec.vector.VectorizedColumnarSerDe	VectorizedColumnarSerDe is used by Vectorized query execution engine for columnar based storage supported by RCFile.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDayOfMonthLong	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFHourLong	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMinuteLong	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMonthLong	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFSecondLong	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFTimestampFieldLong	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFUnixTimeStampLong	Return Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFWeekOfYearLong	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFYearLong	Expression to get year as a long.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastIntHashUtil	Utilities for mapr join in vectorization mode.
org.apache.hadoop.hive.ql.io.VectorizedRCFileInputFormat	A MapReduce/Hive Vectorized input format for RC files.
org.apache.hadoop.hive.ql.io.VectorizedRCFileRecordReader	RCFileRecordReader.
org.apache.hadoop.hive.ql.io.orc.FileDump	A tool for printing out the file structure of ORC files.
org.apache.hadoop.hive.ql.io.orc.InStream	Class to define input stream.
org.apache.hadoop.hive.ql.io.orc.Metadata	Metadata stored in underlying db.
org.apache.hadoop.hive.ql.io.orc.MetadataReader	Class to read and process metadata.
org.apache.hadoop.hive.ql.io.orc.OrcProto	Class to serialize data stored in orc.
org.apache.hadoop.hive.ql.io.orc.OrcUtils	Utilities to process orc files.
org.apache.hadoop.hive.ql.io.orc.RecordReaderFactory	Factory to create ORC tree readers.
org.apache.hadoop.hive.ql.io.orc.RecordReaderUtils	Stateless methods shared between RecordReaderImpl and EncodedReaderImpl.

Class	Description
org.apache.hadoop.hive.ql.io.orc.StripeStatistics	Information about index data stored in stripe.
org.apache.hadoop.hive.ql.io.orc.TreeReaderFactory	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.log.PidDailyRollingFileAppender	Logging pids in file.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveConfigContext	Hive configuration context.
org.apache.hadoop.hive.ql.optimizer.calcite.reoperators.HiveLimit	Define limit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reoperators.HiveSort	Define sort operator.
org.apache.hadoop.hive.ql.parse.VariableSubstitution	The Hive variable substitution mechanism was designed to avoid some of the code that was getting baked into the scripting language on top of Hive.
org.apache.hadoop.hive.ql.session.DependencyResolver	Creating list of dependency jars.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregator	Counter statistics aggregator.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorSpark	Counter statistics aggregator for Spark.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorTez	This class aggregates stats via counters and does so for Tez Tasks.
org.apache.hadoop.hive.ql.stats.CounterStatsPublisher	Counter statistics publisher.
org.apache.hadoop.hive.ql.udf.UDFRegExp	UDFRegExp.
org.apache.hadoop.hive.shims.Hadoop20SShims	Implementation of shims against Hadoop 0.20 with Security.
org.apache.hadoop.hive.shims.HiveEventCounter	Hive event counter.
org.apache.hadoop.hive.shims.Jetty20SShims	In order to be compatible with multiple versions of Jetty, all parts of the Jetty interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hadoop.mapred.WebHCatJTShim20S	This is in org.apache.hadoop.mapred package because it relies on JobSubmissionProtocol which is package private
org.apache.hive.benchmark.vectorization.VectorizationBenchmark	Measures the performance for vectorization.
org.apache.hive.jdbc.ZooKeeperHiveClientHelper	Resolve to a host:port by connecting to ZooKeeper and picking a host randomly.
org.apache.hive.service.cli.Column	Column.
org.apache.hive.service.cli.Type	Type.
org.apache.hive.service.cli.thrift.TArrayTypeEntry	Array type entry.
org.apache.hive.service.cli.thrift.TBinaryColumn	Binary column.
org.apache.hive.service.cli.thrift.TBoolColumn	Boolean column.
org.apache.hive.service.cli.thrift.TBoolValue	Boolean value.
org.apache.hive.service.cli.thrift.TByteColumn	Byte column.
org.apache.hive.service.cli.thrift.TByteValue	Byte value.

Class	Description
org.apache.hive.service.cli.thrift.TCLIService	Command line interface service.
org.apache.hive.service.cli.thrift.TCLIServiceConstants	Command line interface constants.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenReq	Cancel delegation token request.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenResp	Cancel delegation token response.
org.apache.hive.service.cli.thrift.TCancelOperationReq	Cancel operation request.
org.apache.hive.service.cli.thrift.TCancelOperationResp	Cancel operation response.
org.apache.hive.service.cli.thrift.TCloseOperationReq	Close operation request.
org.apache.hive.service.cli.thrift.TCloseOperationResp	Close operation response.
org.apache.hive.service.cli.thrift.TCloseSessionReq	Close session request.
org.apache.hive.service.cli.thrift.TCloseSessionResp	Close session response.
org.apache.hive.service.cli.thrift.TColumn	Column.
org.apache.hive.service.cli.thrift.TColumnDesc	Column description.
org.apache.hive.service.cli.thrift.TColumnValue	Column value.
org.apache.hive.service.cli.thrift.TDoubleColumn	Double column.
org.apache.hive.service.cli.thrift.TDoubleValue	Double value.
org.apache.hive.service.cli.thrift.TExecuteStatementReq	Execute statement request.
org.apache.hive.service.cli.thrift.TExecuteStatementResp	Execute statement response.
org.apache.hive.service.cli.thrift.TFetchOrientation	Fetch orientation.
org.apache.hive.service.cli.thrift.TFetchResultsReq	Fetch results request.
org.apache.hive.service.cli.thrift.TFetchResultsResp	Fetch results response.
org.apache.hive.service.cli.thrift.TGetCatalogsReq	Get catalogs request.

Removed Interfaces

Interface	Description
org.apache.hadoop.hive.ql.exec. <i>FetchFormatter</i>	(For internal-use only) Used in ListSinkOperator for formatting final output
org.apache.hadoop.hive.ql.io.orc. <i>BinaryColumnStatistics</i>	Statistics for binary columns.
org.apache.hadoop.hive.ql.io.orc. <i>BooleanColumnStatistics</i>	Statistics for boolean columns.
org.apache.hadoop.hive.ql.io.orc. <i>ColumnStatistics</i>	Statistics that are available for all types of columns.
org.apache.hadoop.hive.ql.io.orc. <i>CompressionCodec</i>	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc. <i>CompressionCodec.Modifier</i>	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc. <i>ConversionTreeReaderFactory</i>	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.io.orc. <i>DateColumnStatistics</i>	Statistics for DATE columns.

Interface	Description
org.apache.hadoop.hive.ql.io.orc.DecimalColumnStatistics	Statistics for decimal columns.
org.apache.hadoop.hive.ql.io.orc.DirectDecompressionCodec	Decompression codec.
org.apache.hadoop.hive.ql.io.orc.DoubleColumnStatistics	Statistics for float and double columns.
org.apache.hadoop.hive.ql.io.orc.IntegerColumnStatistics	Statistics for all of the integer columns, such as byte, short, int, and long.
org.apache.hadoop.hive.ql.io.orc.PositionProvider	An interface used for seeking to a row index.
org.apache.hadoop.hive.ql.io.orc.StringColumnStatistics	Statistics for string columns.
org.apache.hadoop.hive.ql.io.orc.StripeInformation	Information about the stripes in an ORC file that is provided by the Reader.
org.apache.hadoop.hive.ql.io.orc.TimestampColumnStatistics	Statistics for Timestamp columns.
org.apache.hadoop.hive.ql.stats.StatsCollectionTaskIndependent	Marker interface to differentiate between stats publisher / aggregator which don't track stats per task, as oppose to others which do.

Deprecated API in Hive 2.1

The following classes, interfaces, and fields have been deprecated in Hive 2.1.

Deprecated Classes

org.apache.hadoop.hive.ql.exec.ByteWritable
org.apache.hadoop.hive.serde.Constants
org.apache.hadoop.hive.ql.io.FlatFileInputFormat

Troubleshooting Hive and Tez

This section includes Hive and Tez troubleshooting tips.

HDFS Literal Deprecated

Starting in Hive-2.3, the `hdfs` literal is deprecated. Specifying a table location using the `hdfs` URI scheme will cause queries to fail because the Hive parser recognizes the `hdfs` literal in the `LOCATION` key word and triggers HDFS encryption, which is not supported.

If you use the `hdfs` literal with the `LOCATION` keyword in Hive queries:

```
CREATE TABLE IF NOT EXISTS i (id INT) LOCATION 'hdfs:///i';
```

The system logs the following warning:

```
LOG.warn("hdfs:// is deprecated filesystem and will be removed in future
releases. Use maprfs://
instead");
```

To avoid `hdfs` literal issues, update all instances of `hdfs` with `maprfs` in tables, partitions, and databases. Also update the `hive-site.xml` file to remove `hdfs` from the URI scheme list.

Update hive-site.xml

Remove `hdfs` from the `hive.exim.uri.scheme.whitelist` Hive configuration property in `hive-site.xml`, as shown:

```
<property>
<name>hive.exim.uri.scheme.whitelist</
name>
  <value>maprfs,...,..,s3</value>
</property>
```

Update Tables and Partitions

To replace the table and partition location with `maprfs`, run:

```
MariaDB [hive]> update SDS set
LOCATION = REPLACE(LOCATION, 'hdfs',
'maprfs') where LOCATION like
'%hdfs%';
```

Update Databases

To replace the database location with `maprfs`, run:

```
MariaDB [hive]> update
DBS set DB_LOCATION_URI =
REPLACE(DB_LOCATION_URI, 'hdfs',
'maprfs') where DB_LOCATION_URI like
'%hdfs%';
```

Prohibited usage of `datanucleus.schema.autoCreateAll` property

The usage of the `datanucleus.schema.autoCreateAll` property is prohibited in all cases. Instead of using this property, you must run the `schematool` command. Refer to [HIVE-21302](#) for more information.

WebHCat

Secure WebHCat operations depend on the Hive metastore having Kerberos enabled. If Kerberos is not enabled for the Hive metastore, null pointer exceptions similar to the following will appear:

```
2013-10-06 20:38:55,198 ERROR metastore.RetryingHMSHandler
(RetryingHMSHandler.java:invoke(134)) -
MetaException(message: java.lang.NullPointerException)

java.util.concurrent.ThreadPoolExecutor$Worker.runTask(ThreadPoolExecutor.ja
va:895)
    at
java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:9
18)
```

If you are updating to the `mapr-hive-2.3.6-mapr-1912 (EEP-6.3.0)` package, you should manually replace the old `webhcat-default.xml` configuration file with the new one and restart the WebHCat service:

```
cp /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat.new/
webhcat-default.xml /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat/
```

Hive in an Azure Cluster

When Hive services are installed on an Azure cluster, it is possible that the services will not start because Azure assigns too long (over 64 symbols) host names. Perform following steps to fix this issue:

NOTE: This issue is fixed on MapR core 6.0.1 starting from build 20180320175756.GA-1.x86_64.

1. Edit the `/etc/hosts` file:

```
nano /etc/hosts
```

This is an example of a `/etc/hosts` file for an Azure cluster:

```
127.0.0.1    localhost localhost.localdomain localhost4
localhost4.localhostdomain4
::1         localhost localhost.localdomain localhost6
localhost6.localhostdomain6
172.24.8.4  anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0
172.24.8.5  anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1
172.24.8.6  anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2
172.24.8.7  anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3
172.24.8.8  anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4
```

2. Add a short alias for each node:

NOTE: You can use any short alias. In this example, `vm0`, `vm1`, `vm2`, `vm3`, and `vm4` are used:

```
127.0.0.1    localhost localhost.localdomain localhost4
localhost4.localhostdomain4
::1         localhost localhost.localdomain localhost6
localhost6.localhostdomain6
172.24.8.4  anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0 vm0
172.24.8.5  anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1 vm1
172.24.8.6  anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2 vm2
172.24.8.7  anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3 vm3
172.24.8.8  anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4 vm4
```

3. Perform step 1 and 2 for each node in the cluster.

Tez Upgrade Issues

- Preserving configuration on Ubuntu is not supported from EEP 4.1.1 and EEP 5.0.0 (1803) to EEP 6.0.0 (1808) or EEP 5.0.1 (1808).
- Preserving Tomcat configuration is not supported from any previous EEP to EEP 6.0.0 (1808).

- You must manually stop the Tomcat service and delete the Tomcat folder as a precondition if you are updating or upgrading Tez from the following EEPs:
 - EEP 4.0.0
 - EEP 4.1.0

User Names, Group Names, and LDAP

LDAP configuration allows you to use group names and usernames with spaces, so it is possible to name groups with spaces in them, for example, `domain users`. The following structure is possible in the MapR FileSystem:

```
drwxr-xr-x  - afischer      domain users      0 2018-10-03 16:10 /
user/abc
drwxr-xr-x  - mapr        mapr              0 2018-10-05 16:51 /
user/def
drwxr-xr-x  - dschexnayder domain users      8 2018-10-10 13:30 /
user/xyz
drwxr-xr-x  - mapr        mapr              1 2018-10-09 14:23 /user/
hive
drwxr-xr-x  - mapr        mapr              11 2018-10-10 01:56 /user/
mapr
drwxr-xr-x  - mlitovsky   domain users      0 2018-10-06 11:08 /user/
hjbs
drwxr-xr-x  - pcurtis     domain users      5 2018-10-04 19:33 /user/
jknd
drwxr-xr-x  - mapr        mapr              3 2018-10-08 16:29 /user/
ewkd
drwxr-xr-x  - talvarez    domain users      0 2018-10-04 17:02 /
user/lkd
```

According to [HADOOP-12505](#), the Hadoop community does not allow spaces in group names, and because of that so does Hive. Each time you perform a query in Hive on a group name that has a space, you will see the following exception:

```
-chgrp: 'domain users' does not match expected pattern for group
```

The workaround is to not use spaces in group names or user names.

HiveServer 2 takes time to start because of `get_all_databases`

Materialized view registry and cache is introduced in [HIVE-14496](#) for Hive 2.3.0.

The goal of the cache is to avoid parsing and creating logical plans for the materialized views at query runtime. When a query arrives, you need to consult this cache and extract the logical plans for the views (which are already parsed) from it. Materialized view registry class scans all databases and tables in each database during initialization and that may cause long time to start HiveServer2.

Property `hive.materializedview.enable.views.registry` is added to control the usage of materialized view registry:

Property: `hive.materializedview.enable.views.registry`

Default value: `true`

Description: In case of a large amount of databases and tables in Hive, usage of materialized view registry and cache force HiveServer2 to scan all of them in order to cache the query plan for a view. This leads to an extremely long time for HiveServer2 to start.

This property is used to disable view registry and cache for this case. To disable materialized view registry and cache, add the following to `hive-site.xml` and restart Hive services.

```
<property>
  <name>hive.materializedview.enable.views.registry</name>
  <value>>false</value>
</property>
```

Database and Table Names Containing a Dot (.)

HIVE-16907 rejects queries with database and table names that contain a dot (.), and this behavior is backported to Hive 2.3.

Databases and tables that contain a dot (.) in the name are not supported now. For example:

```
{code}
insert into `tdb.t1` select * from t2;
{code}
Throws error:
{code}
FAILED: SemanticException
org.apache.hadoop.hive.ql.parse.SemanticException: Line 1:12 Table or
database name may not contain dot(.) character 'tdb.t1'
{code}
```

Avoid using unsupported characters in database and table names.

Hive Logging

This section describes Hive logging for Hive 2.1 and later releases and includes information about log splitting.

Hive Logging (Hive 2.3 and Later)

For Hive 2.3 and later starting with EEP 6.3.0, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

Hive Log Folder Structure

Table 1 shows the Hive log folder structure:

Table

Folder or File	Description
<code>\${HIVE_HOME}/log</code>	Root folder for all Hive logs
<pre>hive-\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.out hive-\${ADMIN_USER}-metastore-\${HOSTNAME}.out init_derby_db_\${TIMESTAMP}.log</pre>	Each service has a separate file for logging
<code>\${HIVE_HOME}/log/\${ADMIN_USER}</code>	Root folder for admin cluster logs
<pre>\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log \${ADMIN_USER}-metastore-\${HOSTNAME}.log \${ADMIN_USER}-cli-\${HOSTNAME}.log</pre>	Cluster admin log files

Table (Continued)

Folder or File			Description
<code>\${HIVE_HOME}/log/\${ADMIN_USER}/webhcat/</code>			Root folder for webHcat logs
		<code>webhcat.log</code> <code>webhcat-console.log</code> <code>webhcat-console-error.log</code>	WebHcat log files
<code>\${HIVE_HOME}/log/\${OTHER_USER}</code>			Root folder for a user other than the admin user
		<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	CLI log for a user other than the admin user

In Table 1:

This element	Represents
<code>\${HIVE_HOME}</code>	The Hive home folder, which is usually <code>/opt/mapr/hive/hive</code> .
<code>\${ADMIN_USER}</code>	The admin user of a cluster that runs HiveServer2 and HiveMetastore daemons. Usually, this is the <code>mapr</code> user.
<code>\${HOSTNAME}</code>	The name of the host where the daemon runs.
<code>\${TIMESTAMP}</code>	The date and time of log creation.
<code>\${OTHER_USER}</code>	A user other than the admin user.
<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	The log file that is created when <code>\${OTHER_USER}</code> launches the Hive CLI.

Content of Log Files

Table 2 shows the content of the log files:

Table

File Name	Description
<code>hive-\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.out</code>	Contains information about when the HiveServer2 daemon was started and the PID of the file.
<code>hive-\${ADMIN_USER}-metastore-\${HOSTNAME}.out</code>	Contains information about when the HiveMetastore daemon was started and the PID of the file.
<code>\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log</code>	Contains information from the HiveServer2 daemons. This file also contains the job progress.
<code>\${ADMIN_USER}-metastore-\${HOSTNAME}.log</code>	Contains information from the HiveMetastore daemons.
<code>\${ADMIN_USER}-cli-\${HOSTNAME}.log</code>	Created when a user runs the Hive CLI over the <code>\${ADMIN_USER}</code> . This file contains the job progress.
<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	Created when a user runs the Hive CLI over the <code>\${OTHER_USER}</code> . This file also contains the job progress.
<code>init_derby_db_\${TIMESTAMP}.log</code>	Created if and only if Hive was configured for Apache Derby through cluster installation.

Log Files in a Multinode Hive Installation

Table 3 shows a Hive multinode installation (that is, Hive packages installed on different nodes):

Table

	Hive Metastore	HiveServer2	HiveWebHCat
node1			
node2			
node3			

See Table 4 for the log configurations:

Table

File or Folder Name	node1	node2	node3
hive- <code>{ADMIN_USER}</code> -metastore- <code>{HOSTNAME}</code> .out			
<code>{ADMIN_USER}</code> -metastore- <code>{HOSTNAME}</code> .log			
hive- <code>{ADMIN_USER}</code> -hiveserver2- <code>{HOSTNAME}</code> .out			
<code>{ADMIN_USER}</code> -hiveserver2- <code>{HOSTNAME}</code> .log			
/webhcat/			
webhcat.log			
webhcat-console.log			
webhcat-console-error.log			
/ <code>{ADMIN_USER}</code> /

[Disabling Log Splitting of Hive Log Files](#) on page 4224

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

[Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID](#) on page 4224

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

Hive Logging (Hive 2.1 and Later)

For certain Hive 2.1 and later releases, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

The Hive log information in this topic applies to Hive 2.1 and later releases beginning with the 1803 release-date identifier. Included are the Hive releases in Ecosystem Packs (EEPs) 3.0.3, 3.0.4, 3.0.5, 4.1.1, 4.1.2, 4.1.3, 4.1.4, 5.0.x, 6.0.x, 6.1.1, and 6.2.0. For more information about release-date identifiers, see [Release History for EEPs](#) on page 6636.

Default log folder structure

Hive logs have the following folder structure:

```

{HIVE_HOME}/log
{HIVE_HOME}/log/hive-{ADMIN_USER}-hiveserver2-{HOSTNAME}.out
{HIVE_HOME}/log/hive-{ADMIN_USER}-metastore-{HOSTNAME}.out
{HIVE_HOME}/log/init_derby_db_{TIMESTAMP}.log
{HIVE_HOME}/log/{ADMIN_USER}

```

```

${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-metastore-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console-error.log
${HIVE_HOME}/log/${OTHER_USER}
${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log
    
```

Here:

```

${HIVE_HOME} - Hive home folder. Usually this is /opt/mapr/hive/hive.
${ADMIN_USER} - Admin user of cluster that runs HiveServer2 and
HiveMetastore daemons. Usually this is mapr.
${HOSTNAME} - Name of the host where a daemon runs.
${TIMESTAMP} - Date and time of log creation.
${OTHER_USER} - Not an admin user.
    
```

Content of log files

Files ``${HIVE_HOME}/log/hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out`` and ``${HIVE_HOME}/log/hive-${ADMIN_USER}-metastore-${HOSTNAME}.out`` contain information about when HiveServer2 and HiveMetastore daemons are stated, and what are their PIDs.

Files ``${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`` and ``${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`` contain information from HiveServer2 and HiveMetastore daemons. File ``${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`` also contains job progress.

The ``${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log`` file is created when somebody runs Hive CLI over the ``${OTHER_USER}``. The ``${OTHER_USER}-hiveserver2-${HOSTNAME}.log`` file contains job progress.

The ``${HIVE_HOME}/log/init_derby_db-${TIMESTAMP}.log`` file is created if and only if Hive was configured for Derby Db through cluster installation.

Log files on multi node Hive installation

Consider Hive multi node installation (that is Hive packages are installed on different nodes). See Table 1:

Table

	Hive Metastore	HiveServer2	HiveWebHCat
node1			
node2			
node3			

See Table 2 for log configurations.

Table

	node1	node2	node3
<code>`\${HIVE_HOME}/logs/hive-\${ADMIN_USER}-metastore- \${HOSTNAME}.out`</code>			
<code>`\${HIVE_HOME}/logs/\${ADMIN_USER}/\${ADMIN_USER}-metastore- \${HOSTNAME}.log`</code>			
<code>`\${HIVE_HOME}/logs/hive-\${ADMIN_USER}-hiveserver2- \${HOSTNAME}.out`</code>			

Table (Continued)

	node1	node2	node3
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat-console.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat-console-error.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}</code>			

Related concepts

[Disabling Log Splitting of Hive Log Files](#) on page 4224

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

[Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID](#) on page 4224

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

Disabling Log Splitting of Hive Log Files

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

This information is valid for Hive-2.1+ starting from the EEP-1803 release.

Disabling Log Splitting of Hive Log Files

You can disable splitting the Hive log files into HiveServer2 and Metastore log files. To write all logs to the `hive.log` file, use these steps:

1. Edit the `hive-env.sh` file to set `SPLIT_HIVE_LOGS_INTO_FILES` property to `false`.

```
export SPLIT_HIVE_LOGS_INTO_FILES="false"
```

NOTE: To restore the default behavior from your previous Hive log configuration, set the `SPLIT_HIVE_LOGS_INTO_FILES` property to `true`, or comment out this property and restart Hive services.

2. Restart Hive services.

Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

To enable this feature, you must create a `hive-log4j2.properties` file, if one does not already exist, and then edit it:

1. If the `hive-log4j2.properties` file does not exist, create it from the template:

```
cp /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties.template /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties
```

2. Edit the `hive-log4j2.properties` file to replace Daily Rolling File Appender (DRFA) with the PID appender:

```
#property.hive.root.logger = DRFA
property.hive.root.logger = PID
#appenders = console, DRFA
appenders = console, PID
```

3. Restart Hive services.

The resultant Hive log structure is as follows:

The HiveServer2 log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where HiveServer2 log file is placed.
- `<PID>` is the process ID of HiveServer2.

The Metastore log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-metastore-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where Hive Metastore log file is placed.
- `<PID>` is the process ID of Hive Metastore.

Logging CLI session

After splitting logs for HiveServer2 and Hive Metastore, CLI log appears separately for each CLI session at `${HIVE_HOME}/logs/<USERNAME>`.

A log file is created for every launched CLI session:

```
${HIVE_HOME}/log/<USERNAME>/
<USERNAME>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where `<PID>` is process identifier of the CLI session.

Viewing Hive Audit Logs

Starting in EEP 7.1.0, you can view Hive audit logs for connected, disconnected, and total connected users.

To view audit logs, add the following property in the `hive-site.xml` file:

```
<property>
  <name>hive.enable.full.list.of.connected.users</name>
  <value>true</value>
</property>
```

By default, logs are updated every five seconds.

The following table describes the Hive Parameters used to manage the user audit logs:

Parameter	Default value	Description
<code>hive.enable.full.list.of.connected.users</code>	false	Enables the logging of the users currently connected to Hive when set to true. Use for debugging purposes only.
<code>hive.full.list.of.connected.users.update.interval</code>	5	Enables the log updates for currently connected Hive users in seconds. Must be used with the <code>hive.enable.full.list.of.connected.users</code> parameter. Use for debugging purposes only.

How to View Audit Logs

Enable the `hive.enable.full.list.of.connected.users` property in `hive-site.xml` file. You can view audit logs for connected, disconnected, and total connected users in HiveServer2 logs located in `${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log` directory.

The following examples show you how the audit logs look in different scenarios:

Logs display for new user connection

Log entries for connected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Connected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

Logs display for disconnected user

Log entries for disconnected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Disconnected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

Logs display for total connected users

Log entries for total connected users start with a message `-Start of connected users list`, and provides the current session ID, username, IP address of the user, operation count, active time, idle time,

authentication type, and end with a message- End of the connected user's list.

```
INFO [pool-4-thread-1]
SessionManager.audit: Start of the
connected users list

INFO [pool-4-thread-1]
SessionManager.audit:
sessionId=c6261d49-1a71-4404-8cad-9cac
11a28151 user=mapr ip=192.168.33.11
operationCount=0 activeTime(s)=268
IdleTime(s)=268, auth=MAPRSASL

connected user's list
```

How to Audit a Hive Query

The audit log in HiveServer2 allows you to trace the activities of a Hive query. The log entries for a Hive query includes username, user's IP address, query ID, query type, and query string.

To audit a Hive query, run any Hive query and then see the HiveServer2 logs located in `${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log` directory.

```
INFO [HiveServer2-Background-Pool: Thread-54]
Driver.audit: user=mapr ip=192.168.33.11
queryId=mapr_20210426155754_ace67f82-9a0c-4d0e-9ac5-c529b9798ec7 query
type=SHOWTABLES queryStr=show tables
```

HttpFS

HttpFS provides a service that enables you to submit HTTP REST calls to distributed file systems. You can use HttpFS to perform read and write operations on the file system.

This section includes the following topics:

Authentication on Secure Clusters for HttpFS

In secure clusters, HttpFS can use any of the following authentication methods:

- HttpFS authentication, such as native security (data-fabric SASL)
- Kerberos (for which additional configuration is required)

- Plain security using PAM, which is determined automatically

In a secure cluster, HttpFS runs a script to set the following properties by default. In a non-secure cluster, you must add the following properties manually to the `httpfs-site.xml` file:

```
httpfs.hadoop.authentication.type=multiauth
httpfs.authentication.type=multiauth
```

Configuring HttpFS

You can configure the following features to perform distributed file system operations securely through HttpFS.

The following topics describe how to configure various security mechanisms for HttpFS.

Kerberos Authentication for HttpFS

Complete the following steps to enable Kerberos security on nodes that run the HttpFS service:

Step 1: Set up a Kerberos Principal and keytab File

Each node running the HttpFS service must have a keytab file (`/opt/mapr/conf/mapr.keytab`) and these two principals:

- HTTP/<fully.qualified.domain.name>
- mapr/<fully.qualified.domain.name>

NOTE: For complete instructions on generating a Kerberos principal and keytab file, see [Configuring Kerberos](#).

To check whether the keytab already exists, and if it contains the two necessary principals, run the `klist` command with the `-k` (keytab keys), `-e` (encryption type) and `-t` (timestamp) options:

```
$ klist -ket /opt/mapr/conf/mapr.keytab
```

The output from this command displays the following information:

- KVNO (key version number)
- Timestamp (the time the key was generated)
- Principal names
- Encryption types

If the keytab file does not exist, or does not contain both principals, generate them by following these steps:

1. Generate a Kerberos principal for the `mapr` user. The principal is of the form `mapr/<fully.qualified.domain.name>@<your-realm>.com`, where `<fully.qualified.domain.name>` is unique for each HttpFS node. In the following example, `perfnod153.perf.lab@dev-maprtech.com` is used for the `<fully.qualified.domain.name>@<your-realm>.com`.

```
$ kadmin
kadmin: addprinc -randkey mapr/perfnod153.perf.lab@dev-maprtech.com
```

2. Generate a Kerberos principal for `HTTP/<fully.qualified.domain.name>`. This is required for Kerberos authentication of the HttpFS server using HTTP SPNEGO.

```
$ kadmin
kadmin: addprinc -randkey HTTP/perfnodel53.perf.lab@dev-maprtech.com
```

3. If the current node does not already have a keytab file created for another service, create one and name it `mapr.keytab`. Note that each node references the same keytab file (usually located at `/opt/mapr/conf/mapr.keytab`), and each keytab file can have multiple principals.

```
kadmin: ktadd -k /opt/mapr/conf/mapr.keytab mapr/perfnodel53.perf.lab
```

4. Change the owner of the keytab file from the `root` user (the default) to the `mapr` user.

```
$ chown mapr:mapr /opt/mapr/conf/mapr.keytab
```

5. Set read-only permissions on the `mapr.keytab` file.

```
$ chmod 600 mapr:mapr /opt/mapr/conf/mapr.keytab
```

Step 2: Verify Credentials in the keytab File

To test that the credentials in the `mapr.keytab` file work, run the `klist` command with the three options:

- `-k` for keytab keys
- `-e` for encryption type
- `-t` for timestamp

Example

```
$ klist -ket /opt/mapr/conf/mapr.keytab
```

Verify that the output lists only one key version number (KVNO) for each principal name. If you see the same principal listed more than once with a different KVNO, this could indicate a problem. The latest version number is used, which means you might not be able to log in to the node and authenticate with your user credentials.

Here is sample output for a node that has the HttpFS and CLDB services installed.

```
Keytab name: FILE:/opt/mapr/conf/mapr.keytab
KVNO Timestamp Principal
-----
-----
2 07/18/14 18:50:07 mapr/perfnodel53.perf.lab@dev-maprtech
(aes256-cts-hmac-shal-96)
2 07/18/14 18:50:07 mapr/perfnodel53.perf.lab@dev-maprtech (arcfour-hmac)
2 07/18/14 18:50:08 mapr/perfnodel53.perf.lab@dev-maprtech (des3-cbc-shal)
2 07/18/14 18:50:08 mapr/perfnodel53.perf.lab@dev-maprtech (des-cbc-crc)
2 07/18/14 18:50:26 HTTP/perfnodel53.perf.lab@dev-maprtech
(aes256-cts-hmac-shal-96)
2 07/18/14 18:50:26 HTTP/perfnodel53.perf.lab@dev-maprtech (arcfour-hmac)
2 07/18/14 18:50:26 HTTP/perfnodel53.perf.lab@dev-maprtech (des3-cbc-shal)
2 07/18/14 18:50:26 HTTP/perfnodel53.perf.lab@dev-maprtech (des-cbc-crc)
6 07/18/14 18:50:56 mapr/my.cluster.com@dev-maprtech
(aes256-cts-hmac-shal-96)
```

```
6 07/18/14 18:50:56 mapr/my.cluster.com@dev-maprtech (arcfour-hmac)
6 07/18/14 18:50:56 mapr/my.cluster.com@dev-maprtech (des3-cbc-sha1)
6 07/18/14 18:50:57 mapr/my.cluster.com@dev-maprtech (des-cbc-crc)
```

In the example, the following principals are listed for the `perfnode153.perf.lab` node:

- `mapr/perfnode153.perf.lab@dev-maprtech` for authenticating to the HttpFS service
- `HTTP/perfnode153.perf.lab@dev-maprtech` for communicating securely over HTTP
- `mapr/my.cluster.com` for authenticating to the CLDB service

Step 3: Modify the `httpfs-site.xml` File

About this task

A Kerberos-ready version of the `httpfs-site.xml` file called `httpfs-site.xml.kerberos` is provided in `/opt/mapr/httpfs/httpfs-<version>/etc/hadoop`. Edit this file and specify the Kerberos principal name for the nodes running HttpFS, restart the HttpFS server, and then test the set-up. Each step is explained here.

Note that the directory differs based on the `httpfs` version:

- In EEP 7.0.1 and earlier, the directory is `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-site.xml`.
- In EEP 7.1.0 and later, the directory is `/opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop/httpfs-site.xml`.

To set up the `httpfs-site.xml` file for each node running the HttpFS service, follow these steps:

Procedure

1. Assign a new name to the existing `httpfs-site.xml` file (to preserve the original version when the file gets overwritten in step 2):

- In 7.0.1 and earlier, run:

```
cp /opt/mapr/httpfs/httpfs-1.0/etc/hadoop httpfs-site.xml
httpfs-site.xml.original
```

- In 7.1.0 and later, run:

```
cp /opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop httpfs-site.xml
httpfs-site.xml.original
```

2. Copy the `kerberos` version (`httpfs-site.xml.kerberos`) to the existing `httpfs-site.xml` file:

- In 7.0.1 and earlier, run:

```
cp /opt/mapr/httpfs/httpfs-1.0/etc/hadoop httpfs-site.xml.kerberos
httpfs-site.xml
```

- In 7.1.0 and later, run:

```
cp /opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop httpfs-site.xml.kerberos
httpfs-site.xml
```

3. Edit the `httpfs-site.xml` file, and insert the principal name as shown, substituting your fully qualified domain name and realm for `perfnodel53.perf.lab@mapr.com`:

```
<property>
  <name>
    httpfs.authentication.kerberos.principal
  </name>
  <value>
    HTTP/perfnodel53.perf.lab@mapr.com
  </value>
</property>
```

4. Restart the HttpFS server so the changes will take effect:

```
maprcli node services -name httpfs -action restart -nodes <node_name>
```

5. Test that security is in place by entering the following command to create a file in the file system. The command will fail if security is not set up correctly:

```
curl --negotiate -u : -b ~/cookiejar.txt -c ~/cookiejar.txt -i -X PUT
"http://perfnodel53.perf.lab:14000/webhdfs/v1/user/mapr/some_file?
op=MKDIRS"
```

Configure the HTTP Header Size (Optional)

About this task

For EEP 7.0.1 and earlier, the `maxHttpHeaderSize` parameter defines the maximum size of the request and response HTTP header, specified in bytes. If it is not specified, this parameter defaults to 8192 (8KB).

When Kerberos security is enabled, you may need to increase this value in the `server.xml` file:

```
/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml
```

Example

```
<Connector port="{httpfs.http.port}" maxHttpHeaderSize="32000"
protocol="HTTP/1.1" connectionTimeout="20000" redirectPort="8443"/>
```

If you do not increase this value, you may encounter errors of the following form:

```
HTTP/1.1 400 Bad Request
```

NOTE: After making this configuration change, restart the HttpFS server.

PAM Authentication for HttpFS

About this task

Complete the following steps to enable PAM authentication for HttpFS.

Procedure

1. Add the `httpfs.hadoop.authentication.type` and `httpfs.authentication.type` properties to the `/opt/mapr/httpfs/httpfs-version/etc/hadoop/httpfs-site.xml` file, as shown. Note that the directory differs based on the httpfs version:

- In EEP 7.0.1 and earlier, the directory is `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-site.xml`.
- In EEP 7.1.0 and later, the directory is `/opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop/httpfs-site.xml`.

```
<property>
  <name>httpfs.hadoop.authentication.type</name>
  <value>multiauth</value>
</property>

<property>
  <name>httpfs.authentication.type</name>
  <value>multiauth</value>
</property>
```

NOTE: On secure clusters, the `multiauth` authentication is enabled by default.

2. Restart the HttpFS service.

```
sudo -u mapr /opt/mapr/httpfs/httpfs-1.0/sbin/httpfs.sh stop
sudo -u mapr /opt/mapr/httpfs/httpfs-1.0/sbin/httpfs.sh start
```

3. After restarting the service, run cURL with the PUT operation, as shown in this example:

NOTE: If HttpFS is configured with plain authentication through PAM, the cURL request must contain a username and password.

```
curl -X PUT "https://mapr:mapr@node1:14000/webhdfs/v1/tmp/example?
op=mkdirs"
```

SSL Security for HttpFS

About this task

On a secure cluster, HttpFS uses the secure-by-default configuration. Use the following topics to explicitly enable custom security on HttpFS.

You also need to enable SSL if [custom security](#) is enabled.

Enabling SSL Security for HttpFS

Enable SSL security for HttpFS using a `ssl_keystore` and `ssl_truststore`. These are generated automatically for a secure cluster in `/opt/mapr/conf/`. When using SSL on insecure clusters, you must manually generate a `keystore` and `truststore`.

About this task

Complete the steps that correlate with your version of HttpFS.

- For EEP 7.1.x and higher, complete the following steps:
 1. Change the value inside property `httpfs.ssl.enabled` in file `/opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop/httpfs-site.xml` to `true`.
 2. Restart the HttpFS server using the following command:

```
maprcli node services -action restart -name httpfs -nodes <node>
```

- For EEP 7.0.x, complete the following steps:

1. To preserve the original version, rename the existing `server.xml` file (`/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml`) to `server.xml.orig`.

```
sudo cp /opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/
server.xml
/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/
server.xml.orig
```

2. Replace the contents of `server.xml` with the contents of `server.xml.https`.

```
sudo cp /opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/
server.xml.https
/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml
```

3. To enable SSL without certificate-based authentication, set the `clientAuth` attribute to **"false"** and set properties related to `keystore` and `truststore` (on a secure cluster, the defaults are already set) in `server.xml` located in `/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/`. For example:

```
<Connector port="${httpfs.http.port}" SSLEnabled="true"
maxThreads="150" scheme="https" secure="true"
clientAuth="false" sslProtocol="TLS"
keystoreFile="/opt/mapr/conf/ssl_keystore"
keystorePass="<ssl-keystore-password>"
truststoreFile="/opt/mapr/conf/ssl_truststore"
truststorePass="<ssl-keystore-password>"/>
```

Configuring Certificate-Based Authentication for HttpFS

Starting from EEP 7.1.0, configuration of certificate-based authentication for HttpFS is no longer available. To configure certificate-based authentication for HttpFS, for EEP 7.0.x, you need to make changes to the `server.xml` and `web.xml` file and restart the HttpFS server. To use this method, each client requires a client certificate issued by trusted CA.

Procedure

1. To enable certificate-based authentication, for EEP 7.0.x, perform the following steps:
 - a) Verify that the `clientAuth` attribute is set to **"true"** and set properties related to `keystore` and `truststore` in `server.xml` (`/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml`).

For example:

```
<Connector port="${httpfs.http.port}" SSLEnabled="true"
maxThreads="150" scheme="https" secure="true" clientAuth="true"
sslProtocol="TLS"
keystoreFile="/opt/mapr/conf/ssl_keystore"
keystorePass="<ssl-keystore-password>"
truststoreFile="/opt/mapr/conf/ssl_truststore"
truststorePass="<ssl-keystore-password>"/>
```

- b) In `web.xml` (`/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/webapps/webhdfs/WEB-INF/web.xml`), un-comment the following section:

```
<security-constraint>
  <web-resource-collection>
    <web-resource-name>Protected Context</web-resource-name>
    <url-pattern>/*</url-pattern>
  </web-resource-collection>
  <auth-constraint>
    <role-name>sample</role-name>
  </auth-constraint>
  <user-data-constraint>
    <transport-guarantee>CONFIDENTIAL</transport-guarantee>
  </user-data-constraint>
</security-constraint>

<security-role>
  <role-name>sample</role-name>
</security-role>

<login-config>
  <auth-method>CLIENT-CERT</auth-method>
</login-config>
```

- c) Verify that `tomcat-users.xml` (`/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/tomcat-users.xml`) contains the roles and users in the certificates.

```
<tomcat-users>
  <role rolename="sample" />
  <user name="CN=<hostname>" password="null" roles="sample" />
</tomcat-users>
```

NOTE: The name value should include information from your certificate. For example, `<tomcat-users> <role rolename="sample"/> <user name="CN=www.mapr.com, OU=mapr, O=mapr, L=San Jose, ST=San Jose, C=CA" password="null" roles="sample" /> </tomcat-users>` You can run the following command to view the contents of the certificate file: `openssl x509 -text -in /opt/mapr/hue/hue-<version>/cert.pem`

```
<tomcat-users>
  <role rolename="sample" />
  <user name="CN=www.mapr.com, OU=mapr, O=mapr, L=San Jose,
    ST=San Jose, C=CA" password="null" roles="sample" />
</tomcat-users>
```

2. Restart the HttpFS server using the following command:

```
maprcli node services -name httpfs -action restart -nodes <space
delimited list of nodes>
```

Verifying SSL Security for HttpFS

You need to run `curl` commands to verify that HTTPS is enabled for HttpFS.

Procedure

Run one of the following `curl` commands to check that HTTPS is enabled. These commands fetch the file `some_file.txt` from the file system under `/user/mapr` and attempt to open it securely over HTTPS.

- To check if HTTPS is enabled, run the following command (which differs for non-secure and secure clusters):

- For non-secure clusters:

```
curl "http://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open&user.name=mapr"
```

- For secure clusters:

```
curl -u <user_name> -k "https://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

- If you configured Hue to use SSL encryption with certificate-based authentication for communication with HttpFS, run the following command (which differs for non-secure and secure clusters):

- For non-secure clusters:

```
curl
  --cert /opt/mapr/hue/hue-<version>/cert.pem
  --key /opt/mapr/hue/hue-<version>/hue_private_keystore.pem
  "http://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open&user.name=mapr"
```

- For secure clusters:

```
curl -u <user_name> -k
  --cert /opt/mapr/hue/hue-<version>/cert.pem
  --key /opt/mapr/hue/hue-<version>/hue_private_keystore.pem
  "https://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

Enabling SSL Security for HttpFS with Credential Provider

Starting from EEP-7.1.0, you can enable SSL security for HttpFS with credential provider. The CredentialProvider API is used to separate the use of sensitive tokens, secrets, and passwords from the applications. `hadoop credential create` command is used to provision a password to a particular credential store provider.

About this task

To enable SSL security for HttpFS with credential provider, use the following steps:

Procedure

1. Enable SSL in `etc/hadoop/httpfs-site.xml` configuration file:

```
<property>
  <name>httpfs.ssl.enabled</name>
  <value>>true</value>
  <description>
    Whether SSL is enabled. Default is false, i.e. disabled.
  </description>
</property>
```

2. Use the credential provider to create secure SSL passwords:

```
hadoop credential create ssl.server.keystore.password -value 123 \
  -provider localjceks://file/home/mapr/httpfs.jceks
```

```
hadoop credential create ssl.server.keystore.keypassword -value 123 \
  -provider localjceks://file/home/mapr/httpfs_keypassword.jceks
```

3. Run the Java `keytool` command to create an SSL certificate for the HttpFS server:

```
keytool -genkey -alias jetty -keyalg RSA
```

You will be prompted to answer a series of questions to create a keystore file named `.keystore`.

- You must enter the same password for “keystore password” as the value of the property `ssl.server.keystore.password` set while creating secure SSL passwords.
- You must answer “What is your first and last name?” (i.e. “CN”) with the host name of the machine where the HttpFS Server will be running.

The `.keystore` file will be stored in the HttpFS user home directory.

4. Configure the `etc/hadoop/ssl-server.xml` file to set the SSL keystore location:

```
<property>
  <name>ssl.server.keystore.location</name>
  <value>/home/mapr/.keystore</value>
  <description>Keystore to be used. Must be specified.
</description>
</property>
```

5. Configure the `etc/hadoop/httpfs-site.xml` file with the following property to set credential provider path and enable the credential provider:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://file/home/lmccay/aws.jceks</value>
  <description>Path to interrogate for protected credentials.</
description>
</property>
```

6. Restart the HttpFS server:

```
maprcli node services -action restart -name httpfs -nodes <node>
```

User Impersonation for HttpFS

If you want HttpFS to impersonate a user from a set of hosts, or to impersonate a user that belongs to a set of groups, you can configure the proxy-user functionality. Configuring this functionality enables the proxy user to perform “doAs” operations. To configure proxy-user functionality, add configuration properties to the `httpfs-site.xml` and `core-site.xml` files.

Complete the following steps to configure user impersonation for HttpFS:

1. Add the following configuration properties to the `httpfs-site.xml` file:

- `httpfs.proxyuser.#USER#.hosts`

- `https.proxyuser.#USER#.groups`
2. Replace `#USER#` with the user name of the proxy that can perform “doAs” operations. For the host property, you can add a list of host names as the value. For the group property, you can add a list of groups as the value. Alternatively, you can add a wildcard character (*) as the value for host and group properties. To add multiple users, copy the property and replace `#USER#` with the proxy user name.

Host Example

```
<property>
  <name>https.proxyuser.mapr.hosts</name>
  <value>*</value>
</property>
```

Group Example

```
<property>
  <name>https.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

To use impersonation, issue a cURL command with the `doas=<impersonated_user's name>` parameter.

Example 1

Where `user.name` is `mapr` and `doas` (or the impersonated user's name) is **sampleusername**.

```
curl -i -X PUT -T one
"http://<node_name>:14000/webhdfs/v1/user/mapr/TEST/one
?op=CREATE&user.name=mapr&doas=sampleusername&data=true"
-H "Content-Type:application/octet-stream"
```

Example 2

For any user (and password) other than the `mapr` user (for example, **test_user1**), set the `hadoop.proxyuser.<user_name>.hosts</name>` property in the `/opt/mapr/https/https-<version>/etc/hadoop/https-site.xml` file, as shown. Note that the directory differs based on the version of `https`, for example:

- In EEP 7.0.1 and earlier, the directory is `/opt/mapr/https/https-1.0/etc/hadoop/https-site.xml`.
- In EEP 7.1.0 and later, the directory is `/opt/mapr/https/https-1.1.0/etc/hadoop/https-site.xml`.

```
<property>
  <name>hadoop.proxyuser.<test_user1>.hosts</name>
  <value>*</value>
</property>
```

Run cURL.

Where `trueuser.name` is **test_user1** and `doas` (or the impersonated user's name) is **test_user2**.

```
curl -u fred -i -X PUT -T /etc/hosts --header "Content-Type:application/
octet-stream"
"http://<node_name>:14000/webhdfs/v1/<path_to_test_file>
?op=CREATE&doas=<test_user2>&data=true&user.name=<test_user1>"
```

Network Timeout for HttpFS

The network timeout is the amount of idle time (in milliseconds) that can pass before the HttpFS network connection closes automatically. Depending on your installed EEP, you can use one of the following properties to control the network timeout:

EEP*	Timeout Property	Default Timeout (ms)	Config File
9.0.0 and later	hadoop.http.idle_timeout.ms	60000	/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/httpfs-site.xml
7.0.0 through 8.1.0	hadoop.http.max_idle_time.ms	10000	/opt/mapr/httpfs/httpfs-<version>/etc/hadoop/httpfs-site.xml

*For a guide to the supported EEPs, see [EEP Support and Lifecycle Status](#) on page 6533.

If your applications require the network connection to remain open longer than the default timeout, consider increasing the timeout value. To change the timeout value:

1. Add a timeout property to the `httpfs-site.xml` file. For the appropriate property and the location of the `httpfs-site.xml` file, see the nearby table.

For example, in a cluster installed with EEP 7.0.0, adding the following property to `/opt/mapr/httpfs/httpfs-<version>/etc/hadoop/httpfs-site.xml` sets a timeout value of 30 seconds:

```
<property>
<name>hadoop.http.max_idle_time.ms</name>
<value>30000</value>
</property>
```

2. Restart the HttpFS server so the changes take effect:

```
maprcli node services -name httpfs -action restart -nodes <node_name>
```

Finishing HttpFS Configuration Changes

After making configuration changes for the `mapr-httpfs` package, run the `configure.sh` script on all nodes where the `mapr-httpfs` package was installed:

```
sudo bash /opt/mapr/server/configure.sh -R
```

Troubleshooting HttpFS

About this task

To debug authentication issues, follow these steps:

Procedure

1. Edit the `log4j` properties file located at `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-log4j.properties` and insert the following lines to activate debug capabilities:

```
log4j.logger.org.apache.hadoop.fs.http.server=DEBUG, httpfs
log4j.logger.org.apache.hadoop.lib=DEBUG, httpfs
log4j.logger.org.apache.hadoop.security.authentication.server=DEBUG,
httpfs
```

2. Search the logs located at `/opt/mapr/httpfs/httpfs-1.0/logs` for the words *ERROR* or *Exception*.

Hue

Hue is the open source UI that interacts with Apache Hadoop and its ecosystem components, such as Hive, Pig, and Oozie. It is also a framework for creating interactive Web applications.

For information about Hue versions, see the [Ecosystem Support Matrix](#).

Hue is supported on the following browsers:

Windows	Linux	Mac
Chrome	Chrome	Chrome
Firefox 3.6+	Firefox 3.6+	Firefox 3.6+
Safari 5+		Safari 5+
Internet Explorer 8+		

Hue Feature Support

The following table lists supported and unsupported Hue functionality:

Supported	Not Supported
<p>Query editors</p> <ul style="list-style-type: none"> • Hive (for performing queries on Apache Hive) • Impala (for submitting interactive SQL and HiveQL queries) • DB Query (for viewing data in MySQL, PostgreSQL, Oracle and Sqlite) • Pig (for submitting Pig scripts) • Job Designer (for creating and submitting MapReduce/Streaming/Java jobs) • Spark (beta feature for submitting Spark jobs for hue-3.9.0/3.10.0) • Drill (for performing queries on Apache Drill through JDBC) in hue-3.12 <p>Data browsers</p> <ul style="list-style-type: none"> • Metastore Tables (for managing databases, tables, and partitions of the Hive metastore) • HBase browser (for creating, editing, and searching tables) • Sqoop Transfer (for transferring bulk data between Hadoop and various types of structured datastores) <p>Workflows</p> <ul style="list-style-type: none"> • Oozie (for creating and running workflow and coordinator jobs) <p>Hue 4.X supports ADLS browser for accessing files and directories in Azure Data Lake Store.</p> <p>S3 Browser (for accessing files and directories in Amazon S3)</p> <p>File Browser (for accessing files and directories in file system)</p> <ul style="list-style-type: none"> • Job Browser (for accessing MapReduce applications) • User Admin (for adding, deleting, and managing Hue users and groups) 	<p>Hue integration with the following components is not supported:</p> <ul style="list-style-type: none"> • Sentry 1.6, 1.7 on a secure cluster that uses data-fabric-SASL authentication. <p> NOTE: Sentry 1.6, 1.7 on a secure cluster that uses Kerberos authentication is supported.</p> <ul style="list-style-type: none"> • Solr Search • Zookeeper

Configure Hue

After you install Hue, perform the following configuration steps:

1. Complete the general configuration steps. This includes integrating Hue with ResourceManager and HttpFS.
2. Perform the steps to integrate each additional component that you want to use with Hue.
 - Hive
 - HPE Ezmeral Data Fabric Database
 - Impala

- Oozie
- Spark

You may also want to:

- Configure Security
- Configure DB Query
- Configure Hue Interface Authentication

NOTE: The `hue.ini` file is the main configuration file for running Hue on a cluster. This file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini`. When you update the value of a property in the `hue.ini`, remove any hashes (`##`) that appear directly before the property name. You must also restart Hue for these changes to take effect.

Configure General Hue Settings

The following topics provide instructions for configuring general Hue settings:

Enable User Impersonation for Hue

About this task

To enable Hue to submit requests on behalf of any other user, complete the following steps:

Procedure

1. Verify or configure the following lines to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file for all nodes running ResourceManager:

```
<property>
  <name>hadoop.proxyuser.<default_user>.hosts</name>
  <value>*</value>
</property>

<property>
  <name>hadoop.proxyuser.<default_user>.groups</name>
  <value>*</value>
</property>
```

2. To enable the Hue file browser to view files in the filesystem, add the following proxy user settings in the configuration block of the `httpfs-site.xml`:

```
<!-- Hue HttpFS proxy user setting -->
<configuration>
  <property>
    <name>httpfs.proxyuser.<default_user>.hosts</name>
    <value>*</value>
  </property>

  <property>
    <name>httpfs.proxyuser.<default_user>.groups</name>
    <value>*</value>
  </property>
</configuration>
```

3. Perform any additional Hue configurations and then restart Hue so that the changes will take effect. See [Starting the Hue Webserver](#).

In most cases, `mapr` is the `<default_user>`. The `<default_user>` you specify must also be the `default_user` that is configured in the `[desktop]` section of the `hue.ini`.

NOTE: Based on the ecosystem components that you want to use, additional configuration may be required.

Disable an Application in the Hue Interface (optional)

About this task

If you want to disable an application (such as Impala), follow these steps:

Procedure

1. In the `[desktop]` section of the `hue.ini` file, uncomment the `# app_blacklist=` statement and insert the name of the app you want to disable (`impala` in this example).

NOTE: Do not remove `search` from the `app_blacklist`. The Hue UI will not work if the search application is enabled.

```
# Comma-separated list of apps not to load at server startup.
# Note that rdbms is the name used for dbquery.
app_blacklist=spark,zookeeper,search,impala,sqoop,rdbms
```

NOTE: After removing an application from `app_blacklist`, you must update the Hue internal database to create the tables required for the application that was enabled:

```
sudo /opt/mapr/server/configure.sh -R
```

2. Once all changes are made, restart Hue so the changes will take effect.

NOTE: You can re-enable a blacklisted application at any time, and then restart Hue.

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

Change the File Size Restriction for the File Browser (optional)

About this task

The Hue File Browser will not open files that are 1.0 GB or greater. Starting with Hue 4.2, file size limitation equals 1.0 GB with no way to modify it.

Prevent Hue from Creating User Home Directories

Describes how to disable the automatic creation of user home directories.

By default, Hue creates a directory in the filesystem for a user when the user logs in to the Hue service.

For example, if a `/user` volume is configured in the filesystem, Hue creates a `/user/<username>` directory in the volume each time a user logs in to the Hue service. If a quota is not placed on that `/user` volume, a user could potentially place an unlimited amount of data in the volume.

If you do not want Hue to create a home directory for each user that logs in to the Hue service, disable the `ensure_home_directory` option in the `[desktop]` `[[auth]]` section of the `hue.ini` file, as shown:

```
[desktop]
[[auth]]
ensure_home_directory=false
```

Restart the Hue service for the setting to take effect.

NOTE: This functionality is available by default starting in EEP 7.1.0. Previous versions of EEP can obtain this functionality through a patch. See [Applying a Patch](#) on page 425.

Configure Hue Interface Authentication

You can configure the following user authentication methods for the Hue interface:

Authentication Method	Description
Hue User Administration	Use the Hue interface to create and manage user accounts for each Hue user.
LDAP	Import LDAP users into Hue and then use LDAP to authenticate users with their LDAP credentials. For more information, see Configure Hue with LDAP .
PAM	Use multiple PAM modules to authenticate users. PAM authentication is configured by default. When you use this method, you cannot edit users in the Hue interface.

Using a Non-Default Authentication Method

About this task

The default authentication method is PAM.

To edit the authentication method used for the Hue interface, complete the following steps:

Procedure

1. Set the `backend` property equal to your selected authentication method. For example, to use Hue's user authentication, select `desktop.auth.backend.AllowFirstUserDjangoBackend`.
2. If you choose not to use PAM, comment the `pam_service` property.

Example

Example hue.ini configured to use PAM Authentication

```
[[auth]]
# Authentication backend. Common settings are:
# - django.contrib.auth.backends.ModelBackend (entirely Django backend)
# - desktop.auth.backend.AllowAllBackend (allows everyone)
# - desktop.auth.backend.AllowFirstUserDjangoBackend
# (Default. Relies on Django and user manager, after the first login)
# - desktop.auth.backend.LdapBackend
# - desktop.auth.backend.PamBackend - WARNING: existing users in Hue may be
unaccessible if they not exist in OS
# - desktop.auth.backend.SpnegoDjangoBackend
# - desktop.auth.backend.RemoteUserDjangoBackend
# - libsaml.backend.SAML2Backend
# - libopenid.backend.OpenIDBackend
# - liboauth.backend.OAuthBackend
# (Support Twitter, Facebook, Google+ and LinkedIn
backend=desktop.auth.backend.PamBackend

# The service to use when querying PAM.
pam_service=sudo sshd login
```

Configure Hue with LDAP

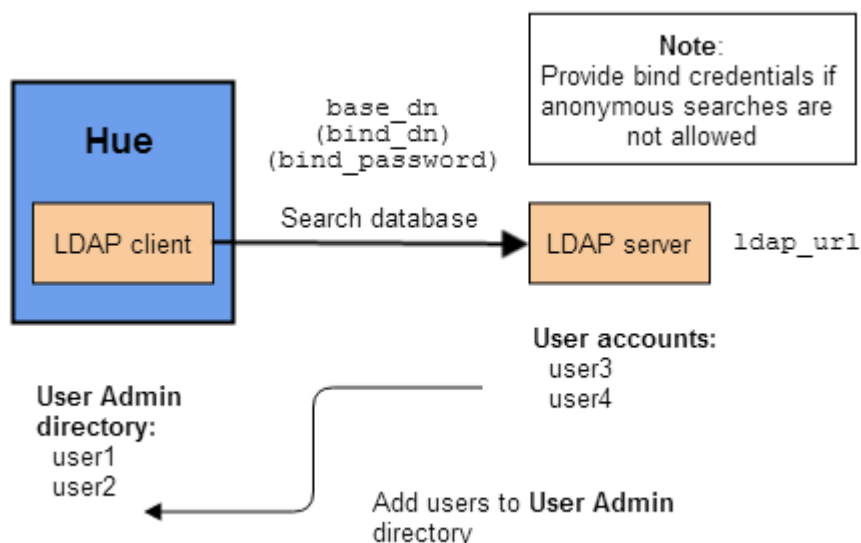

If you use LDAP to authenticate users, you can retrieve user account information from your LDAP database and import it directly into Hue's `User Admin` directory. This way, you do not have to use the Hue interface to create user accounts for each Hue user individually.

Once you import users, you can also use LDAP with Hue to authenticate users with their LDAP credentials. Each of these tasks is explained in the following sections:

Setting up Users from an LDAP Database

About this task

This diagram shows how the LDAP client embedded in Hue searches the LDAP server's database for user names, and then adds them to the `User Admin` directory for Hue.

The following table shows the parameters you need to set in the `ldap` section of the `hue.ini` file so you can import users.

WARNING: The `hue.ini` file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/`.

Parameter	Description	Comments
<code>ldap_url</code>	The URL of your LDAP server.	
<code>base_dn</code>	Top of the search tree, which defines the search scope.	
<code>bind_dn</code>	Distinguished name (DN) of the user to bind as.	Can be omitted for anonymous searches.
<code>bind_password</code>	Password of the bind user.	Can be omitted for anonymous searches.
<code>user_filter</code>	Limits the scope of the search by applying a filter.	This parameter is optional.
<code>user_name_attr</code>	The attribute used for username in the LDAP schema.	Examples: <code>cn</code> (for common name) or <code>uid</code> (for user ID).

To set up Hue users by importing information from an LDAP database:

Procedure

1. Establish communication with the LDAP server by setting the `ldap_url` parameter in the `ldap` section of the `hue.ini` file. Uncomment the line and change the value from the default (`ldap://localhost`) to the URL for your LDAP server.

```
# URL of the LDAP server
##ldap_url=ldap://localhost
```

2. Provide the `base_dn` information to define the search scope. Uncomment the line where `base_dn` is defined and replace with your `base_dn`.

```
# The search base for finding users and groups
## base_dn="DC=mycompany,DC=com"
```

3. If your LDAP server does not support anonymous searches, you need to provide the `bind_dn` and `bind_password`. Uncomment the lines with these parameters and change the values to your `bind_dn` and your `bind_password`.

```
# Distinguished name of the user to bind as -- not necessary if the LDAP
server
# supports anonymous searches
## bind_dn="CN=ServiceAccount,DC=mycompany,DC=com"

# Password of the bind user -- not necessary if the LDAP server
supports
# anonymous searches
## bind_password=
```

4. If you want to narrow the scope of the directory search, specify a `user_filter` in the `users` section under the `ldap` section of the `hue.ini` file. This is optional.

```
[[[users]]]

# Base filter for searching for users
## user_filter="objectclass=*"
```

5. Set the `user_name_attr` parameter in the `users` section under the `ldap` section of the `hue.ini` file. If your LDAP directory schema does *not* use the attribute `sAMAccountName` for the username, uncomment the line and change the value of the `user_name_attr` to the attribute you use. For example, if the directory schema uses the `uid` attribute, change the value of the parameter as shown:

```
[[[users]]]

# The username attribute in the LDAP schema
## user_name_attr=sAMAccountName
```

```
user_name_attr=uid
```

6. Restart `httpfs` so `ldap` settings will take effect.
7. Restart Hue once all configuration changes have been made so the changes will take effect.

Authenticating Hue Users with LDAP Credentials

This section explains how to edit the `ldap` section of the `hue.ini` file to enable Hue user authentication with LDAP credentials. These instructions assume you have completed the steps in [Setting up Users from an LDAP Database](#).

WARNING:

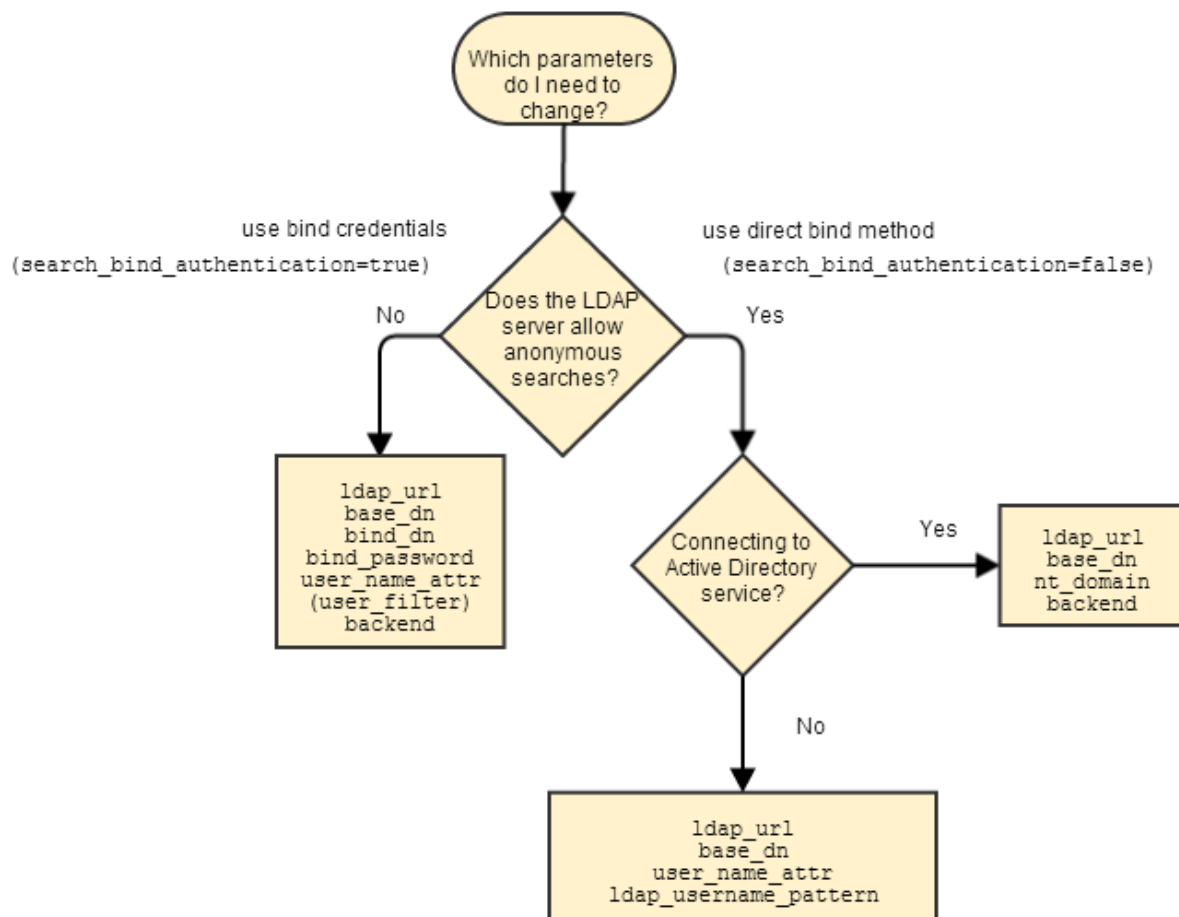

If you switch to authentication through LDAP credentials, the Hue User Admin users will lose superuser privileges unless you take one of the following actions:

- Import one or more superuser accounts from LDAP and assign them superuser permission.
- If you have already enabled the LDAP authentication back end, log into Hue using the LDAP back end, which will create an LDAP user. Next, disable the LDAP authentication back end and use User Admin to give the superuser permission to the new LDAP user.

Before you edit the parameters in the `hue.ini` file, determine whether your LDAP server allows anonymous searches.

- If anonymous searches *are* allowed, use the **direct bind** method.
- If anonymous searches *are not* allowed, use bind credentials (also known as **search and bind**).

The following flow chart shows which parameters you must specify for each of these authentication methods:

These are the parameters you need to set in the `ldap` section of the `hue.ini` file so you can authenticate Hue users with LDAP credentials:

Parameter	Description	Comments
search_bind_authentication	Determines which authentication method to use: search and bind, or direct bind.	<p>When set to <i>true</i>, Hue performs an LDAP search using <code>bind_dn</code> and <code>bind_password</code> as provided in <code>hue.ini</code>. The search can be further limited by the search filter <code>user_filter</code>.</p> <p>When set to <i>false</i>, Hue performs a direct bind to LDAP using the credentials provided from one of these sources:</p> <ul style="list-style-type: none"> the UPN, formed by concatenating <code><shortname></code> (the user name provided on the Hue login page) and <code>nt_domain</code> (if <code>nt_domain</code> is specified) the <code>ldap_username_pattern</code> (if <code>nt_domain</code> is not specified)
nt_domain	The NT domain to connect to. This parameter is <i>only</i> used with Active Directory.	Used with the <i>direct bind</i> method of authentication. If <code>nt_domain</code> is specified, then <code>ldap_username_pattern</code> is ignored.
ldap_username_pattern	Used to connect to directory services other than Active Directory.	Used with the <i>direct bind</i> method of authentication. Usually takes the form "cn=<username>,dc=example,dc=com"
backend	The backend to use for authenticating users.	Needs to be set to <code>desktop.auth.backend.LdapBackend</code> for Hue authentication.

Using Bind Credentials (Search and Bind)

About this task

To use the search and bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

Procedure

1. Set `search_bind_authentication=true`.
2. In the `Authentication backend` section, add the following line after the `##backend=` statement: Hue searches `base_dn` for an entry with `user_name_attr` that contains the user name provided on the Hue login page.

```
backend=desktop.auth.backend.LdapBackend
```

3. Restart Hue once all configuration changes have been made so the changes will take effect.

Using Direct Bind

About this task

To use the direct bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

Procedure

1. Set `search_bind_authentication=false`.
2. If you are using the Active Directory directory service, uncomment the line with the `nt_domain` parameter. Change the value from `nt_domain=mycompany.com` to the NT domain you want to connect to.
3. If you are using any other directory service, uncomment the line with `ldap_username_pattern` and specify the format, such as the one shown here: Note that `<username>` will be replaced by the information provided on the Hue login page.

```
ldap_username_pattern="cn=<username>,dc=example,dc=com"
```

4. Restart Hue once all configuration changes have been made so the changes will take effect.

Configure Hue with DB Query

Hue's DB Query application provides a way to view data in these four database formats:

- SQLite
- MySQL
- PostgreSQL
- Oracle

To configure Hue to work with DB Query, edit the `[librdbms]` section of the `hue.ini` file and change the parameters related to the particular database you are using.

 **WARNING:** To disable the DB Query application, add `rdbms` to the denylist as shown in [Disabling an Application](#).

Default librdbms Settings in hue.ini

Database settings are contained in the `[librdbms]` section of the `hue.ini` file. Two databases (SQLite and MySQL) are already configured in their own sections under the `[[databases]]` heading. Note that PostgreSQL and Oracle work similarly to MySQL, so the `[[mysql]]` section can be treated as a template that can be edited for these two databases.

The DB Query application supports four types of databases, which are configured in the `[[databases]]` section.

The default version of the `librdbms` section of the `hue.ini` file looks like this:

```
#####
# Settings for the RDBMS application
#####
[librdbms]
# The RDBMS app can have any number of databases configured in the
databases
# section. A database is known by its section name
# (i.e. sqlite, mysql, psql, and oracle in the list below).
[[databases]]
```

```

# sqlite configuration.
## [[[sqlite]]]
# Name to show in the UI.
## nice_name=SQLite
# For SQLite, name defines the path to the database.
## name=/opt/mapr/hue/hue-<version>/desktop/desktop.db
# Database backend to use.
## engine=sqlite
# mysql, oracle, or postgresql configuration.
## [[[mysql]]]
# Name to show in the UI.
## nice_name="My SQL DB"
# For MySQL and PostgreSQL, name is the name of the database.
# For Oracle, Name is instance of the Oracle server. For express
edition
# this is 'xe' by default.
## name=mysqlpdb
# Database backend to use. This can be:
# 1. mysql
# 2. postgresql
# 3. oracle
## engine=mysql

# IP or hostname of the database to connect to.
## host=localhost

# Port the database server is listening to. Defaults are:
# 1. MySQL: 3306
# 2. PostgreSQL: 5432
# 3. Oracle Express Edition: 1521
## port=3306

# Username to authenticate with when connecting to the database.
## user=example

# Password matching the username to authenticate with when
# connecting to the database.
## password=example

```

Using DB Query with SQLite

To configure Hue to work with SQLite, edit the `sqlite` section of the `hue.ini` file and replace default values as necessary.

Default sqlite Section

The default version of the `sqlite` section is shown here.

```

# sqlite configuration
## [[[sqlite]]]
# Name to show in the UI.
## nice_name=SQLite

# For SQLite, name defines the path to the database.
## name=/tmp/sqlite.db

# Database backend to use.
## engine=sqlite

```

Modifying the sqlite Section

To configure Hue's DB Query application to work with SQLite, edit the `sqlite` section of the `hue.ini` file as follows:

1. Remove the comment characters (`##`) in front of the `[[[sqlite]]]` statement.
2. Replace the default values for the following parameters as necessary.

Parameter	Default Value	New Value
<code>nice_name</code>	SQLite	The name that you want to appear in the UI
<code>name</code>	<code>/tmp/sqlite.db</code>	The path to the SQLite database

3. Remove the comment characters (`##`) for the parameter values you changed. Otherwise, the default values are used.

Using DB Query with MySQL, PostgreSQL, or Oracle

Instructions for MySQL, PostgreSQL, and Oracle are similar. These instructions show how to configure Hue to work with MySQL. You can adapt the instructions to configure Hue to work with PostgreSQL or Oracle.

The next section shows the default `mysql` section of the `hue.ini` file for illustration. For instructions on configuring Hue so the DB Query application can display data from a MySQL database, see [Modifying the mysql Section](#).

Default mysql Section

The default version of the `mysql` section is shown here.

```
# mysql, oracle, or postgresql configuration.
## [[[mysql]]]
# Name to show in the UI.
## nice_name="My SQL DB"
# For MySQL and PostgreSQL, name is the name of the database.
# For Oracle, Name is the instance of the Oracle server. For      express
edition
# this is 'xe' by default.
## name=mysqlpdb
# Database backend to use. This can be:
# 1. mysql
# 2. postgresql
# 3. oracle
## engine=mysql

# IP or hostname of the database to connect to.
## host=localhost

# Port the database server is listening to. Defaults are:
# 1. MySQL: 3306
# 2. PostgreSQL: 5432
# 3. Oracle Express Edition: 1521
## port=3306

# Username to authenticate with when connecting to the database.
## user=example

# Password matching the username to authenticate with when
```

```
# connecting to the database.
## password=example
```

Modifying the mysql Section

To configure Hue so the DB Query application can work with MySQL, edit the `mysql` section of the `hue.ini` file as follows:

1. Replace the default values for the following parameters.

Parameter	Default Value	New Value
<code>nice_name</code>	"My SQL DB"	The name that you want to appear in the UI
<code>name</code>	<code>mysqldb</code>	The name of the database
<code>host</code>	<code>localhost</code>	IP address or hostname of the database to connect to
<code>user</code>	<code>example</code>	The username to use for authentication when connecting to the database
<code>password</code>	<code>example</code>	The password to use with the username (above) for authentication when connecting to the database

2. Remove the comment characters (`##`) for the parameter values you changed. Otherwise, the default values are used.

Activating DB Query with mySQL

To activate DBQuery with MySQL, follow these steps:

1. Move the `mysql python` library to a back-up location and regenerate it to match the version on the deployment machine. `mv /opt/mapr/hue/hue-<VERSION>/python2.6/site-packages/MySQL_python-1.2.3c1-py2.6-linux-x86_64.egg MySQL_python-1.2.3c1-py2.6-linux-x86_64.egg.bk`
2. Regenerate the `mysql python` library by running the following command: `/opt/mapr/hue/hue-<VERSION>/build/env/bin/pip install mysql-python`

Modifying the mysql Section for PostgreSQL

If you are working with a PostgreSQL database, edit the `mysql` section of the `hue.ini` file and rename it `postgresql`. Next, replace the MySQL default values as shown:

1. Replace the following MySQL default values with PostgreSQL values.

Parameter	Default Value	New Value
<code>nice_name</code>	"My SQL DB"	The name that you want to appear in the UI
<code>name</code>	<code>mysqldb</code>	The name of the database
<code>engine</code>	<code>mysql</code>	<code>postgresql</code> (the database backend)
<code>port</code>	<code>3306</code>	<code>5432</code>

2. Replace the following default values with your host machine, username, and password.

Parameter	Default Value	New Value
host	localhost	IP address or hostname of the database to connect to
user	example	The username to use for authentication when connecting to the database
password	example	The password to use with the username (above) for authentication when connecting to the database

3. Remove the comment characters (##) at the beginning of each line where you changed parameter values. Otherwise, the MySQL default values are used.

Modifying the mysql Section for Oracle

If you are working with an Oracle database, edit the `mysql` section of the `hue.ini` file and rename it `oracle`. Next, replace the MySQL default values as shown:

1. Replace the following MySQL default values with Oracle values.

Parameter	Default Value	New Value
nice_name	"My SQL DB"	The name that you want to appear in the UI
name	mysqldb	The instance of the Oracle server (for express edition, this is xe by default)
engine	mysql	oracle (the database backend)
port	3306	1521 (for Oracle Express Edition)

2. Replace the following default values with your host machine, username, and password.

Parameter	Default Value	New Value
host	localhost	IP address or hostname of the database to connect to
user	example	The username to use for authentication when connecting to the database
password	example	The password to use with the username (above) for authentication when connecting to the database

3. Remove the comment characters (##) at the beginning of each line where you changed parameter values. Otherwise, the mysql default values are used.

Configure the Hue Database

The Hue server stores user-account information, the job submission history, and Hive queries in one of the following supported databases:

- SQLite, the embedded Hue database (the default database)
- MySQL

- PostgreSQL
- Oracle
- MariaDB

NOTE: Using SQLite is not recommend.

Configure Hue to Store Data in MySQL or MariaDB

About this task

Hue supports MySQL 5.5.x - 5.7.x. Hue does not support MySQL 8 and later.

Procedure

1. Configure the database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties with your database connection parameters:

```
[desktop]
...
[[database]]
engine=mysql
host=<host>
port=3306
user=<user>
password='<password>'
name=<database>
```

Example of configuration:

```
[desktop]
...
[[database]]
engine=mysql
host=node1
port=3306
user=hue
password=hue_password
name=hue
```

If the connection is secured through SSL/TLS, specify the CA, Cert, and Key paths, as shown in the following example:

```
[desktop]
[[database]]
...
options='{ "ssl": { "key": "/path/to/client-key.pem", "cert": "/path/to/client-cert.pem", "ca": "/path/to/ca.pem" } }'
```

You can find detailed documentation for other options in the Django [Connecting to the Database](#) documentation.

2. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

More information

<https://docs.djangoproject.com/en/1.11/ref/databases/#version-support>

Configure Hue to Store Data in PostgreSQL

About this task**Procedure**

1. Install the following packages:

CentOS	<code>yum install gcc python-devel postgresql-devel</code>
SLES	<code>zypper install gcc python-devel postgresql-devel</code>
Ubuntu	<code>apt-get install gcc python-dev postgresql-server-dev-all</code>

2. Ensure that the `pg_config` command is in your `PATH`. For example, on CentOS with PostgreSQL 9.4 development package from the [postgresql.org](https://www.postgresql.org) official repository, you need to add the directory with `pg_config` manually:

```
export PATH="/usr/pgsql-9.4/bin:$PATH"
```

3. Install the Python `psycopg2` package in Hue:

```
cd /opt/mapr/hue/hue-<version>
source ./bin/activate
pip install psycopg2
deactivate
```

- Configure database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties for your database connection parameters:

```
[desktop]
...
[[database]]
engine=postgresql_psycopg2
host=<host>
port=5432
user=<user>
password=<password>
name=<database>
schema=<schema>
```

Example of Configuration

```
[desktop]
...
[[database]]
engine=postgresql_psycopg2
host=node1
port=5432
user=hue
password=hue_password
name=hue
schema=public
```

- Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

- Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

Configure Hue to Store Data in Oracle Database

About this task

NOTE: To configure Hue with Oracle 12, you need the [Oracle 11 Instant Client Base and SDK](#).

Procedure

- Install the following packages:

CentOS	<code>yum install gcc python-devel</code>
SLES	<code>zypper install gcc python-devel</code>
Ubuntu	<code>apt-get install gcc python-dev</code>

- Ensure that the library required to install the Oracle module in Hue is available through the `LD_LIBRARY_PATH` environment variable. The module that provides support for Oracle in Hue requires the `libclntsh.so` library to be available through the `LD_LIBRARY_PATH` environment variable. Typically, the library is located under the `$ORACLE_HOME` or `$ORACLE_HOME/lib` directories. Also, the library might include a version in the filename (for example, `libclntsh.so.11.1`), but the Oracle module for Hue requires it to be named `libclntsh.so`.

- a) Ensure that the `ORACLE_HOME` environment variable is set:

```
export ORACLE_HOME=<path_to_oracle_installation>
```

- b) Use the `find` command to locate the library:

```
find "$ORACLE_HOME" -name "libclntsh.so*"
```

- c) Go to the directory and ensure that the library is available and has the proper filename. If not, you can create a symbolic link:

```
ln -s libclntsh.so.11.* libclntsh.so
```

- d) Add the following variables to the Hue environment configuration by creating a file in `/opt/mapr/hue/hue-<version>/bin/env.d/`. For example, create `/opt/mapr/hue/hue-<version>/bin/env.d/99custom` with the following content:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME:$LD_LIBRARY_PATH"
```

or the following, depending on your Oracle configuration:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME/lib:$LD_LIBRARY_PATH"
```

3. Depending on the Oracle instant client version installed:

- a) Run the shell script:

```
$ sudo sh -c "echo /usr/lib/oracle/<version-number>/client64/lib
> /etc/ld.so.conf.d/oracle-instantclient.conf"
```

- b) Use the `ldconfig` command to create the linking:

```
$ sudo ldconfig
```

- c) Verify the dynamic linking:

```
$ sudo ldconfig -p | grep -i oracle
```

For example:

```
ldconfig -p | grep -i oracle
libcijdbc11.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libcijdbc11.so
libociei.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libociei.so
libocci.so.11.1 (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libocci.so.11.1
libnnz11.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libnnz11.so
libclntsh.so.11.1 (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libclntsh.so.11.1
```

4. Install the Python `cx_Oracle` package in Hue:

```
cd /opt/mapr/hue/hue-<version>
source ./bin/activate
pip install cx_Oracle==5.3
deactivate
```

NOTE: Python `cx_Oracle` version 5.3 is supported.

5. Configure the database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Note these considerations:

- Make sure that you have the appropriate permissions to use LOBs; for example, `SQL GRANT` on `SYS.DBMS_LOB`.
- SID refers to the Oracle system ID, which is used to uniquely identify the database.

```
[desktop]
...
[[database]]
engine=oracle
host=<host>
port=1521
user=<user>
password=<password>
name=<SID of the database>
```

- To achieve a multithreading environment, you can specify the `options={'threaded':true}` parameter in this section. For example:

```
[desktop]
...
[[database]]
engine=oracle
host=node1
port=1521
user=hue
password=hue_password
name=XE
options={'threaded':true}
```

By setting the `port=0` parameter, you can use the Oracle Service Name instead of specifying the SSID. For example:

```
[desktop]
...
[[database]]
engine=oracle
port=0
user=hue
password=hue_password
name=node1:1521/hue
```

6. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

7. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

About this task

Edit the `hue.ini` file to use an Oracle database:

For detailed steps, see `inspectdb` and `dumpdb` Hue commands, <http://gethue.com/hue-api-execute-some-builtin-commands/>.

Configure Hue with Security

Based on the Hue version and the version of the other components that Hue communicates with, you can configure the following security features:

NOTE: You cannot enable both Kerberos and data-fabric-SASL on the same cluster.

Configure Hue to use Kerberos

After you set up a Kerberos principal and keytab file, you can configure Hue to use the Kerberos authentication protocol.

After you set up a Kerberos principal and keytab file, enable the Kerberos Ticket Renewal service, update `hue.ini` and `core-site.xml` with the required parameters, and restart the Warden and Hue services.

Enabling the Kerberos Ticket Renewer Service

The Kerberos Ticket Renewer service (`kt_renewer`) renews tickets for the Hue service. Hue automatically starts the `kt_renewer` process on clusters that use Kerberos for authentication. Kerberos tickets have a default expiration time of 7 days. The `kt_renewer` service extracts the Kerberos ticket from the keytab file and renews the ticket before it expires.

You can access the `kt_renewer` process log files in the following locations:

- `${HUE_HOME}/logs/kt_renewer.out`
- `${HUE_HOME}/logs/kt_renewer.log`

To use the Kerberos Ticket Renewer service:

1. Enable the Kerberos Ticket Renewer Service:
 - In the `kdc.conf` file, add the `max_renewable_life` parameter.
 - In the `krb5.conf` file, add the `renew_lifetime` parameter.
2. Update the `hue.ini` file to include the Kerberos credentials cache path (`ccache_path`) and ticket renewal frequency (`keytab_reinit_frequency`), as shown in the following example:

```
[desktop]
    [[kerberos]]
    ...
    # Path to keep Kerberos credentials cached
    # ccache_path=/tmp/custom_hue_krb5_ccache
    # Frequency in seconds with which Hue will renew its
keytab
    # keytab_reinit_frequency=86400
    ...
```

Modifying the hue.ini File

In the `kerberos` section of the `hue.ini` file, make the following changes:

1. Supply the path to Hue's Kerberos keytab file.
2. Supply the Kerberos principal name for Hue.
3. Supply the path to `kinit`.
4. In the `[[yarn_clusters]] [[default]]` section:
 - If you are using a certificate signed by the CA (Certificate Authority), set the `ssl_cert_ca_verify` value to `True`.
 - If you are using a self-signed certificate or no certificate, leave the value set to `False`.
5. **For Hue with secure Hive:** In the `beeswax` section, make sure that the `hive_conf_dir` property points to a directory containing a valid `hive-site.xml` file (either the original or a synced copy).
6. **Optional:** To enable SSL encryption, see [Enable SSL Encryption Between Hue and Hive](#).
7. Make sure that you specified a fully-qualified domain name (FQDN) for all services integrated with Hue that uses Kerberos:

HttpFS: Set the `webhdfs_url` property in the `[hadoop] [[hdfs_clusters]] [[default]]` section.

HiveServer2: Set the `hive_server_host` property in the `[beeswax]` section.

Impala: Set the `server_host` property in the `[impala]` section.

Spark: Set the `livy_server_url` property in the `[impala]` section.

NOTE: Support for Kerberos integration with Livy was introduced in Hue 4.X.

Oozie: Set the `oozie_url` property in the `[liboozie]` section.

HBase: Set the `hbase_clusters` property in the `[hbase]` section.

Drill: Refer to section.

The changes are summarized in the following `hue.ini` files, which you can use as a template:

```
[desktop]
[[kerberos]]
# Path to Hue's Kerberos keytab file
hue_keytab=/opt/mapr/conf/mapr.keytab

# Kerberos principal name for Hue
# hue_principal=mapr/<hostname>@<realm>
# Substitute your hostname and realm in the example below
hue_principal=mapr/perfnodel81.perf.lab@dev-maprtech

# Path to keep Kerberos credentials cached
# ccache_path=/tmp/custom_hue_krb5_ccache
# Frequency in seconds with which Hue will renew its keytab
# keytab_reinit_frequency=86400

# Path to kinit
# Note that the actual path depends on which Linux OS you are using
kinit_path=/usr/bin/kinit

[beeswax]
```

```

# If Kerberos security is enabled, use fully-qualified domain name
# (FQDN)
hive_server_host=<FQDN of Hive Server>
# Hive configuration directory, where hive-site.xml is located.
hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
# Change this if your Hive is secured
security_enabled=true
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

[impala]
# Host of the Impala Server (one of the Impalad)
server_host=<FQDN of Impalad>
# Kerberos principal
impala_principal=mapr/perfnodel81.perf.lab@dev-maprtech

[hadoop]
...
[[hdfs_clusters]]
[[[default]]]
# Enter the filesystem uri
fs_defaultfs=maprfs:///

# Use WebHdfs/HttpFs as the communication mechanism.
# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://<FQDN of HttpFS>:14000/webhdfs/v1

# Change this if your HDFS cluster is secured
security_enabled=True

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI
...
[[yarn_clusters]]
[[[default]]]
# Enter the host on which you are running the ResourceManager
## resourcemanager_host=localhost

# The port where the ResourceManager IPC listens on
## resourcemanager_port=8032

# Whether to submit jobs to this cluster
submit_to=true

# Change this if your YARN cluster is secured
security_enabled=true

# URL of the ResourceManager API
## resourcemanager_api_url=https://localhost:8090

# URL of the ProxyServer API
## proxy_api_url=https://localhost:8090

# URL of the HistoryServer API
history_server_api_url=https://localhost:19890

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

# In secure mode (HTTPS), if SSL certificates from Resource Manager's
# Rest Server have to be verified against certificate authority
ssl_cert_ca_verify=False

```

```
[spark]
# The Livy Server URL.
livy_server_url=https://<FQDN of Livy Server>:8998

# Whether Livy requires client to perform Kerberos authentication.
security_enabled=True

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
mechanism=GSSAPI

[liboozie]
# The URL where the Oozie service runs on. This is required in order for
# users to submit jobs.
oozie_url=https://<FQDN of Oozie>:<oozie_port_number>/oozie

# Requires FQDN in oozie_url if enabled
security_enabled=true
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

[hbase]
# Comma-separated list of HBase Thrift servers for clusters in the format
of '(name|host:port)'.
# Use full hostname with security.
# If using Kerberos we assume GSSAPI SASL, not PLAIN.
hbase_clusters=(Cluster|<FQDN of Hbase Thrift Server>:9090)
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI
```

NOTE: You need to manually set `security_enabled` property to `true` and `mechanism` property to `GSSAPI` for a Kerberised environment. These options are automatically configured only on a `data-fabric-SASL` cluster.

Modifying the `core-site.xml` File

In the `core-site.xml` file, provide the shortname for the Kerberos principal as shown. In addition, verify that you configured the proxyuser during configuration. See [Configure Hue](#) for details.

```
<!-- Hue security configuration -->
<property>
  <name>hue.kerberos.principal.shortname</name>
  <value>mapr</value>
</property>
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value> <!-- A group that all users of Hue belong to, or the
wildcard value "*" -->
</property>
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value><hue_server_FQDN></value>
</property>
```

Restarting Warden and Hue

After you make all the changes to the files listed above, restart Warden and Hue so the changes will take effect.

Configure Hue to use Data Fabric-SASL

You can configure Hue to use Data Fabric-SASL for its communications with various components on a secure cluster. Hue automatically detects and sets the security configuration of the cluster and its components. Therefore, in some cases, minimal configuration is required.

The following components are supported by Hue with Data Fabric-SASL:

- HttpFS
- YARN and Spark History Server
- Hive
- Livy
- HBase Thrift
- Oozie
- Drill

NOTE: For secure by default clusters or for clusters where the `customSecurity` flag is not added, Hue automatically sets `security_enabled` to `true` and `mechanism` to `MAPR-SECURITY` for these components. In all other cases, `{security_enabled}` and `{mechanisms}` variables are set to `false` and `none` respectively, but these options can be configured manually for custom setups.

An example of a default configuration with automatically defined `security_enabled` and `mechanism` properties for HttpFS is as follows:

```
[hadoop]
[[hdfs_clusters]]
  # HA support by using HttpFs
  [[[default]]]
  ...
  # Change this if your HDFS cluster is secured
  security_enabled=${security_enabled}

  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=${mechanism}
  ...
```

An example of a manual configuration of `security_enabled` and `mechanism` properties for HttpFS is as follows:

```
[hadoop]
[[hdfs_clusters]]
  # HA support by using HttpFs
  [[[default]]]
  ...
  # Change this if your HDFS cluster is secured
  security_enabled=true

  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=MAPR-SECURITY
  ...
```

NOTE: After you configure the `hue.ini`, you must restart Hue. However, if you configure multiple sections of the same file, you can restart Hue one time after your updates are complete.

Configure LDAP Authentication Between Hue and Hive

About this task

You can configure Hue to use LDAP Authentication when it communicates with HiveServer2. Before you configure Hue to use LDAP authentication with HiveServer2, verify that HiveServer2 is configured to use LDAP authentication. For more information, see [Configure HiveServer2 to use LDAP Authentication](#) on page 4047.

Complete the following steps to configure LDAP authentication between Hue and Hive:

Procedure

1. Configure Hue to connect to Hive with LDAP authentication:

- a) Configure the `[beeswax]` section of the `hue.ini`: set `mechanism` option.

```
[beeswax]
...
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=LDAP
```

- b) Configure the `[beeswax]` section of the `hue.ini` (for Hive integration only):

```
[beeswax]
...
# Override the default desktop username and password of the hue user
used for authentications with other services.
# e.g. Used for LDAP/PAM pass-through authentication.
auth_username=sampleuser
auth_password=123456
...
```

Or configure the `[desktop]` section of the `hue.ini` to set the username and password for all services that require username/password authentication:

```
[desktop]
...
# Default LDAP/PAM/.. username and password of the hue user used
for authentications with other services.
# Inactive if password is empty.
# e.g. LDAP pass-through authentication for HiveServer2 or Impala.
Apps can override them individually.
auth_username=sampleuser
auth_password=123456
...
```

2. **Optional:** Configure Hue to authenticate users through LDAP. See [Configure Hue with LDAP](#).

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <space delimited
list of nodes>
```

Configure PAM Authentication Between Hue and Hive

About this task

In Hue 3.10, you can configure Hue to use PAM authentication when it communicates with HiveServer2. Before you configure Hue to use PAM authentication with HiveServer2, verify that HiveServer2 is configured to use PAM authentication. See [Configure HiveServer2 to Use PAM Authentication](#) for more information.

Complete the following steps to configure PAM authentication between Hue and Hive:

Procedure

1. Configure the `[beeswax]` section of the `hue.ini` file. Set the `mechanism` option to `none`. Set the `auth_username` and `auth_password` options in the `[desktop]` or `[beeswax]` sections of `hue.ini` (where `auth_username` and `auth_password` are the user credentials for the user who authenticates the Hue service with HiveServer2).

The following example summarizes these changes:

```
[desktop]
...
# Default LDAP/PAM/.. username and password of the Hue user used
for authentication with other services.
# Inactive if password is empty.
# e.g. LDAP pass-through authentication for HiveServer2 or Impala.
Apps can override them individually.
auth_username=mapr
auth_password=<user_password>
...
[beeswax]
...
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=none
```

2. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <Hue node>
```

Enable SSL Encryption Between Hue and Hive

About this task

Hue automatically determines when SSL encryption is enabled in Hive by reading the `hive-site.xml` file.

NOTE: Starting from EEP 6.0.0, SSL encryption is enabled by default for Hive in a secured cluster. To configure SSL for Hive on a non-secure cluster, refer to [Hive Encryption](#) on page 4057.

Procedure

1. The following example shows how to correctly configure the directory path where the `hive-site.xml` file is located in the `hive_conf_dir` property in `[beeswax]` section of the `hue.ini` file:

```
[beeswax]
...
# Hive configuration directory, where hive-site.xml is located
hive_conf_dir=/opt/mapr/hive/hive-2.3/conf
```

- The following examples show how to enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in `[desktop]` section of the `hue.ini` file:

Example for enabling certificate verification:

```
[desktop]
...

# Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=true
```

Example for disabling certificate verification:

```
[desktop]
...

# Path to default Certificate Authority certificates. As an example: /
path/to/cacert.pem
# ssl_cacerts=

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=false
```

- After you change these properties, restart Hue to apply your changes:

```
maprcli node services -name hue -action start -nodes <hostname>
```

Enable SSL Encryption Between Hue and HttpFS

About this task

As of HttpFS 1.0-1504 and Hue 3.7-1505, you can enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure cluster that is version 4.0.2 or greater.

Complete the following steps to enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure cluster:

Procedure

- Configure HttpFS to use SSL or verify that HttpFS is configured to use SSL. For details, see [SSL Security for HttpFS](#).
- Set the `webhdfs_url` property in the `[hadoop] [[hdfs_clusters]] [[[default]]]` section of the `hue.ini` file to contain the correct URL for HttpFS with the HTTPS schema and domain of the HttpFS server:

```
[hadoop]
[[hdfs_clusters]]
[[[default]]]
# Use WebHdfs/HttpFs as the communication mechanism.
# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
```

- You can enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in the `[desktop]` section of the `hue.ini` file.

Example for enabling certificate verification:

```
[desktop]
...

# Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=true
```

Example for disabling certificate verification:

```
[desktop]
...

# Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
# ssl_cacerts=

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=false
```

- [OPTIONAL] Configure mutual authentication between Hue and HttpFS. Add the following configuration in the `hue.ini` file under the `[hadoop]` `[[hdfs_clusters]]` `[[[default]]]` section.

- `mutual_ssl_auth=True`
- `ssl_cert=/path/to/certificate.pem`
- `ssl_key=/path/to/private_key.pem`

Use absolute paths for `ssl_cert` and `ssl_key`. Hue does not support private keys with a passphrase in this step.

The changes are summarized in the following example in the `hue.ini` file, which you can use as a template:

```
[hadoop]
[[hdfs_clusters]]
# HA support by using HttpFs
[[[default]]]
# Use WebHdfs/HttpFs as the communication mechanism.
# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
...
# SSL certificate based authentication
ssl_cert=/path/to/certificate.pem
ssl_key=/path/to/private_key.pem
```

5. Restart Hue.

```
maprcli node services -name hue -action start -nodes <ip_address>
```

6. To test that SSL encryption is enabled for HttpFS, run the following command:

```
curl -k --cert /path/to/certificate.pem --key /path/to/private_key.pem
"https://node1.cluster.com:14000/webhdfs/v1?
op=GETFILESTATUS&user.name=mapr"
```

Troubleshoot Hue Security Issues

To troubleshoot Kerberos security issues, enable the debugger by changing the following setting in the `/opt/mapr/conf/env.sh` file:

```
# uncomment the following line to debug client kerberos issues
#MAPR_KERBEROS_DEBUG="-Dsun.security.krb5.debug=true -Dsun.security.spnego.d
ebug=true -Djavax.net.debug=all"
```

Under the Hue installation directory, check `logs/runcpserver.log` for errors. Some sample error messages are shown below.

Could not start SASL

If you see this message, try using [renewable tickets](#):

```
TypeError: TTransportException('Could not start SASL: Error in
sasl_client_start (-1) SASL(-1): generic failure: GSSAPI Error: Unspecified
GSS failure. Minor code may provide more information (Ticket expired)',)
is not JSON serializable
```

Run the `kinit` command to generate a new ticket with a long running lifetime, then restart the Hue webserver.

Configuration Error

If you see this message, it means that the ticket generated by the `kinit` command from `maprlogin` kerberos was not copied to `/tmp/hue_krb5_ccache`:

```
Caused by: javax.security.auth.login.LoginException: Configuration Error -
useTicketCache should be set to true to use the ticket cache /tmp/
hue_krb5_ccache
```

This can happen when you generate a new ticket after the original ticket expires and forget to copy it into the ticket cache. Run the following command to copy the ticket into the ticket cache:

```
kinit -k -t /opt/mapr/conf/mapr.keytab -c /tmp/hue_krb5_ccache mapr/
perfnodel81.perf.lab@dev-maprtech
```

Password incorrect while getting initial credentials

This message (Password incorrect while getting initial credentials) appears when you create a keytab file, but try to authenticate with a password. The act of creating a keytab causes a new random key to be placed in the Kerberos database and into the keytab file (`/opt/mapr/conf/mapr.keytab`). That key does not have a password associated with it, so you can only authenticate using the keytab.

If you want to authenticate with a password, run the `cpw` command in `kadmin` instead of the `ktadd` command.

Integrate Hue

This section contains the following topics with information for integrating Hue with other ecosystem components:

Integrate Hue with HPE Ezmeral Data Fabric Database Binary Tables

You can use the Hue HBase application to access HPE Ezmeral Data Fabric Database binary tables.

NOTE: In order to use the Hue HBase application, you need to install the HBase Client and the HBase Thrift Gateway. For more information, see the [Installing Core and Ecosystem Components](#) on page 91.

Step 1: Setting up HPE Ezmeral Data Fabric Database Binary Table Mapping

To use the Hue HBase application to access HPE Ezmeral Data Fabric Database binary tables, you need to set the `hbase.table.namespace.mappings` property.

Table Mapping Naming Conventions

A table mapping takes the form `name:map`, where `name` is the table name to redirect and `map` is the modification made to the name. The value in `name` can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

Example: Map Table Names to HPE Ezmeral Data Fabric Database

In the following example, the `hbase.table.namespace.mappings` property is set so that any flat table name, such as `mytable`, is treated as a HPE Ezmeral Data Fabric Database table in the directory `/tables_dir/mytable`.

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>*:/tables_dir</value>
</property>
```

Once you finish enabling table mapping in the `core-site.xml` file, start (or restart) the HBase thrift server so the changes will take effect.

```
maprcli node services -name hbasethrift -action start -nodes node001
```

Step 2: Configure Hue for HPE Ezmeral Data Fabric Database

About this task

To configure Hue for HPE Ezmeral Data Fabric Database, edit the `hbase` section of the `hue.ini` file, which looks like this:

```
[hbase]
# Comma-separated list of HBase Thrift servers for
# clusters in the format of '(name|host:port)'.
## hbase_clusters=(Cluster|localhost:9090)

# Hard limit of rows or columns per row fetched before truncating.
## truncate_limit = 500
```

In this file, make the following changes:

Procedure

1. Uncomment the `## hbase_clusters=(Cluster|localhost:9090)` statement and provide the list of HBase Thrift servers.

```
hbase_clusters=(<clustername1>|<hostname1>:9090),(<clustername2>|
<hostname2>:9090)[,...]
```

2. Uncomment the `truncate_limit` statement and change the value if necessary.

Integrate Hue with Hive

Describes how to integrate Hue with Hive through settings in the `hue.ini` file.

About this task

By default, Hue connects to a single instance of HiveServer2 through the `hive_server_host` parameter in `hue.ini`; however, if high availability (HA) is enabled for HiveServer2, Hue can leverage that. If one instance of HiveServer2 goes down, the client automatically connects to another instance of HiveServer2.

Verify the Hive Version

Before you integrate Hue with HiveServer2 (HA or single instance), verify that the path specified in the `hive_conf_dir` property applies to the Hive version that you have installed. If needed, update the path to reflect the Hive version that you have installed.

```
# Hive configuration directory, where hive-site.xml is located
hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
```

If Hue and Hive are installed on separate nodes, you must also copy the Hive `conf` directory to the Hue node.

Integrating Hue with HiveServer2 High Availability

If you want Hue to leverage HiveServer2 HA, [enable high availability for HiveServer2](#), and update the `hue.ini` file to include the following properties and settings:

```
[beeswax]
#Whether to use service discovery for llap.
hive_discovery_llap = true
#Is llap (hive server interactive) running in HA.
hive_discovery_llap_ha = true
#Whether to use service discovery for HiveServer2.
hive_discovery_hs2 = true
```

```
[libzookeeper]
#ZooKeeper ensemble; comma-separated list of host/port.
ensemble=<host:port>:5181
```

Note that the `hive_server_host` and `hive_server_port` properties in `hue.ini` are not required if using HiveServer2 HA. Service discovery overrides the server and thrift port.

Perform any additional Hue configurations and then restart Hue for changes to take effect. See [Starting the Hue Webservice](#).

Integrating Hue with a Single Instance of HiveServer2

Update the `beeswax` section of the `hue.ini` file to include the following properties and settings:

 **NOTE:** This is not required on a single node cluster.

```
[beeswax]

# Host where HiveServer2 is running.
# If Kerberos security is enabled, use fully-qualified domain name (FQDN).
hive_server_host=<FQDN of Hive Server>

# Port that HiveServer2 Thrift server runs on.
hive_server_port=10000
```

Perform any additional Hue configurations and then restart Hue for changes to take effect. See [Starting the Hue Webservice](#).

Configuring Data and Metadata Directories

When Hue and Hive are used together, they are usually configured to share metadata and data directories. However, you can create separate directories for Hue and Hive.

The locations of the shared directories are specified by the following properties in the `hive-site.xml` file:

- `hive.metastore.uris` (the hostname and port of the Hive Metastore node)
- `hive.metastore.warehouse.dir` (the directory where the default database for the warehouse is located)

See [Configure Shared Hive Data and Metadata Directories for Hue](#) and [Configure Separate Hive Data and Metadata Directories for Hue](#) for more information.

Configure Shared Hive Data and Metadata Directories for Hue

About this task

To configure shared Hive data and metadata directories for Hue:

Procedure

1. Change the `hive.metastore.uris` property as shown:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://localhost:9083</value>
  <description> URI where clients contact Hive metastore server </
description>
</property>
```

NOTE: The `hive.metastore.warehouse.dir` property can keep its default value and does not need to be changed.

2. Enable Hue impersonation by setting the following property to `true`.

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description> Set this property to enable Hive Metastore service
impersonation in unsecure mode.
  In unsecure mode, setting this property to true causes the metastore
to execute DFS operations
  using the client's reported user and group permissions. Note that
this property must be set on
  BOTH the client and server sides. </description>
</property>
```

3. Set the location of the `sharelib`.

```
<property>
  <name>oozie.service.WorkflowAppService.system.libpath</name>
  <value>/oozie/share/lib</value>
</property>
```

4. To enable the Hive Metastore service to share the embedded Derby database, add the following property blocks to the `hive-site.xml` file on the node running `hiveserver2` to point to the location of the Derby metastore:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:derby:;databaseName=/<local dir>/metastore_db;create=true</
value>
  <description>JDBC connect string for a JDBC metastore</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.apache.derby.jdbc.EmbeddedDriver</value>
  <description>Driver class name for a JDBC metastore</description>
</property>
```

5. To enable the Hive Metastore service to share a MySQL database, add the following property blocks to the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://<ip_address>:3306/hive_11?
createDatabaseIfNotExist=true</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value><UserName></value>
  <description>Substitute the actual username</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value><Password></value>
  <description>Substitute the actual password</description>
</property>
```

Configure Separate Hive Data and Metadata Directories for Hue

About this task

If you want to store Hue data and metadata in separate directories from Hive data and metadata, follow these steps:

Procedure

1. Copy `hive-site.xml` to a new location. (The original `hive-site.xml` file remains in the previous location for use by Hive.)
2. Edit `hue.ini` and change the `hive_conf_dir` property so it points to the new location for `hive-site.xml`.
3. Change the `hive.metastore.warehouse.dir` property in the new `hive-site.xml` file so it points to the directory where Hue data will be located.
4. Change the `hive.metastore.uris` property so it points to the directory for Hue's `metastore_db`.
5. Set the `hive.metastore.execute.setugi` property to `true`.

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description> Set this property to enable Hive Metastore service
impersonation in non-secure mode.
  In non-secure mode, setting this property to true causes the
metastore to execute DFS operations
  using the client's reported user and group permissions. Note that
this property must be set on
  BOTH the client and server sides. </description>
</property>
```

Integrate Hue with Oozie

About this task

Complete the following steps to integrate Hue with Oozie:

Procedure

1. Edit the `hue.ini` file to configure the location where the Oozie service is running. The path to the `hue.ini` file is: `/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini`.

```
[liboozie]
# The URL (host IP address) where the Oozie service is running. This is
# required in order for # users to submit jobs.
oozie_url=http://<ip_address>:<oozie_port_number>/oozie
```

The `<oozie_port_number>` depends on whether your cluster is secure.

2. Enable user impersonation for Oozie through Hue:
 - a) Add the following lines to the `oozie-site.xml` file (the path to the file is: `/opt/mapr/oozie/oozie-4.2.0/conf/oozie-site.xml`):

```
<property>

<name>oozie.service.ProxyUserService.proxyuser.<default_user>.hosts</
name>
  <value>*</value>
</property>
<property>

<name>oozie.service.ProxyUserService.proxyuser.<default_user>.groups</
name>
  <value>*</value>
</property>
```

In most cases, `mapr` is the `<default_user>`. This should be the same default user that is specified in the `hue.ini` and the `core-site.xml`.

- b) Restart Oozie. To restart Oozie, first stop Oozie then start it:

```
maprcli node services -name oozie -action restart -nodes <ip_address>
```

To verify that the Oozie server started, enter:

```
lsof -i:<oozie_port_number>
```

The output from this command should look similar to this:

```
COMMAND PID USER FD TYPE DEVICE SIZE/OFF NODE NAME java 16644 mapr
35u IPv6 69926776 0t0 TCP *:irisa (LISTEN)
```

You can also check Oozie logs to verify that Oozie started. The log is found here: `/opt/mapr/oozie/oozie-<version>/logs/oozie.log`

3. Perform any additional Hue configurations and then restart Hue so that the changes will take effect. See [Starting the Hue Webserver](#).

Integrate Hue with Spark (Experimental Only)

About this task

You can configure Hue to use the Spark Notebook UI. This allows users to submit Spark jobs from Hue.

NOTE: Spark Notebook is a feature that utilizes the Spark REST Job Server (Livy). The `mapr-livy` package must be installed on a node where the `mapr-spark` package is installed or the Livy service will not start.

Procedure

1. In the `[spark]` section of the `hue.ini`, set the `livy_server_host` parameter to the host where the Livy server is running.

```
[spark]
# IP or hostname of livy server.
livy_server_url=https://<host>:8998
```

NOTE: If the Livy server runs on the same node as the Hue UI, you are not required to set this property as the value defaults to the local host.

2. Restart Hue.

```
maprcli node services -name hue -action restart -nodes <hue node>
```

Results

Additional Information

- If needed, you can use the Control System or `maprcli` to start, stop, or restart the Livy Server. For more information, see [Managing Services](#) on page 1065.

NOTE: Troubleshooting Tip

If you have more than one version of Python installed, you may see the following error when executing Python samples:

```
Py4JJavaError: An error occurred while calling
z:org.apache.spark.api.python.PythonRDD.collectAndServe...
```

Workaround:

Set the following environment variables in `/opt/mapr/spark/spark-<version>/conf/spark-env.sh`:

```
export PYSARK_PYTHON=/usr/bin/python2.7
export PYSARK_DRIVER_PYTHON=/usr/bin/python2.7
```

Integrate Hue with Drill

Starting in EEP 6.0, Drill is officially supported with Hue. When you integrate Drill with Hue, users can run Drill queries from the Hue interface and visualize data.

Drill integrates with Hue through configuration options in the `/opt/mapr/hue/hue-<version>/conf/hue.ini` file. A user can authenticate to Hue through Plain, Kerberos, or data-fabric-SASL authentication. The user that authenticates to Hue is the user that runs the Drill queries from Hue.

When connecting to Drill, Hue performs outbound impersonation to Drill as the user that authenticated to Hue. Drill accepts the outbound impersonation from Hue as an inbound impersonation. Drill then performs outbound impersonation to the filesystem or MapR Database.

 **NOTE:** In a secure cluster, you can only access the Hue interface through HTTPS.

 **NOTE:** SSL encryption is currently not supported.

Prerequisites

Note the following prerequisites before you integrate Hue with Drill:

- The cluster must have the latest versions of [Hue](#), [Drill](#), and [HttpFS](#) installed. Hue uses HTTPFS to communicate with the file system. You can see the latest component versions in the [Component Versions for Released EEPs](#). If you install Hue and Drill on a secure cluster, Hue and Drill are installed with the default security configurations and outbound impersonation is enabled.
 - **Installer**

When you install Hue and Drill using the Installer, HTTPFS is installed automatically, and Hue is automatically configured to integrate Drill without having to perform any manual configuration. The installer configures a Zookeeper connection to Drill in `hue.ini`, by default.
 - **Manual Installation**
 - Install HTTPFS and then configure Hue, as described in the following section, *Configuring Hue*
- In a secure cluster, Drill must have [user impersonation enabled](#).
 - Drill has an inbound impersonation policy option, `exec.impersonation.inbound_policies`, that allows the Hue process user (proxy user) to impersonate the Hue authenticated user as an outbound impersonation from Hue to Drill. This option is automatically configured when Drill and Hue are installed using the Installer with default security enabled, or when you run `configure.sh` on a secure cluster. If you do not run `configure.sh`, you must manually add this option to the impersonation configuration in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file, as shown:

```
impersonation.enabled: true,
  impersonation.max_chained_user_hops: 3,
  exec.impersonation.inbound_policies: "[{proxy_principals:{users:
[\"mapr\"}],target_principals:{users:[\"*\"]}}]\",
```

- If you plan to use Kerberos for authentication, you will need to include the Hue keytab file and Kerberos principal name for Hue in the `hue.ini` file. If needed, complete the steps listed in the [Creating a Kerberos Principal and Extracting the Kerberos Ticket from the keytab File](#) sections on the [Configure Hue to use Kerberos](#) on page 4258 page.

Configuring Hue

If you manually installed Hue, Drill, and HTTPFS, you must modify the `hue.ini` file to include the configuration information needed for Hue to connect with Drill and HTTPFS. The `hue.ini` file contains sections where you configure Hue to integrate with various components, like Drill and HTTPFS. You can access the `hue.ini` file in the `/opt/mapr/hue/hue-<version>/desktop/conf` directory. Start/Restart the services after you update the `hue.ini` file.

 **NOTE:** If you installed Hue and Drill using the Installer, these options are populated automatically in the `hue.ini` file; no configuration is required. In a secure cluster, the authentication mechanism defaults to MAPR-SECURITY.

Complete the following steps to integrate Hue with Drill:

1. **Edit the Drill configuration in `hue.ini`.**

The `hue.ini` file contains a `[[[drill]]]` section under which you can see configuration options needed for Hue to connect with Drill. You must uncomment an option (remove the `#` character) in the `hue.ini` file for the option to take effect.

The following tables list and describe the Drill options with possible values and also provide examples:

Options	Descriptions	Examples
<code>connection_type=</code>	<p>Tells Hue how to connect to Drill. Enter one of the following values:</p> <ul style="list-style-type: none"> direct zookeeper <p>A direct connection is a connection in which Hue connects directly to a Drillbit. A ZooKeeper connection is a connection in which Hue communicates with ZooKeeper and ZooKeeper provides Hue with a Drillbit to connect with.</p>	<code>connection_type=zookeeper</code>
<code>drillbits=</code>	<p>Enter the node IP address of the Drillbit that Hue connects with. Only enter a node address if using the "direct" connection_type.</p>	<p><code>drillbits=10.10.100.2:31010</code></p> <p>To list multiple Drillbits, separate each IP address by a comma, as shown:</p> <p><code>drillbits=10.10.100.2:31010, 10.10.100.3:31010</code></p> <p> NOTE: Port 31010 is the user port between nodes in a Drill cluster. This port is needed for an external client to connect into the cluster nodes and for the Drill Web Console.</p>
<code>zk_quorum=</code>	<p>Enter the list of ZooKeeper node IP addresses in the ZooKeeper quorum. Only enter the IP addresses for the ZooKeeper quorum if using the "zookeeper" connection_type.</p>	<code>zk_quorum=10.10.100.3:5181, 10.10.100.4:5181, 10.10.100.5:5181</code>
<code>zk_cluster_id=</code>	<p>Enter the name of the Drill cluster that you want Hue to connect to.</p>	<code>zk_cluster_id=dev-drillbits</code>

<p>mechanism=</p>	<p>The type of authentication enabled. Enter one of the following values:</p> <ul style="list-style-type: none"> • None • GSSAPI • Data Fabric-SECURITY <p>Use None for Plain authentication. Use GSSAPI for Kerberos authentication. Use MAPR-SECURITY for maprsasl.</p> <p>If you set the mechanism to “none” and impersonation is enabled, you must set the username and password to the admin or proxy user that will impersonate Hue end users. You can set these with the user= and password= options.</p> <p>If you set the mechanism to GSSAPI, you must also include the ccache_path= option. For this option, enter the caching location for Kerberos credentials, for example: ccache_path=/tmp/hue_krb5_ccache</p> <p> NOTE: See Configure Hue to use Kerberos on page 4258</p> <p>You can set the Drill Kerberos principal and/or Hue impersonation using the option named “options=.” See “options=” below.</p>	<p>mechanism=none</p>
<p>user=</p>	<p>If using Plain authentication, enter the username. If using another authentication mechanism, do not enter a value.</p> <p>Set the username to the admin or proxy user that will impersonate Hue end users.</p> <p>If impersonation is disabled, the you can set the user to any user. Hue will connect to Drill as the user specified.</p>	<p>user=mapr</p>
<p>password=</p>	<p>If using Plain authentication, enter the password. If using another authentication mechanism, do not enter a value.</p> <p>Set the password for the admin or proxy user that will impersonate Hue end users.</p> <p>If impersonation is disabled, set the password for the use specified.</p>	<p>password=mapr8</p>

password_script=	<p>Indicates which script to run for the database password when a password is required and the password= option is not set. Enter the location of the script.</p> <p>The following shell script is an example of a password script:</p> <pre>#!/bin/bash case \$1 in drill) echo "password_1" ;; some-output) echo "password_2" ;; *) echo "wrong argument" >&2 exit 1 ;; esac</pre>	password_script='/root/hue_password_script/password_script.sh drill'
options=	<p>Additional options related to impersonation and Kerberos authentication. This option takes the following values:</p> <ul style="list-style-type: none"> • impersonation • principal <p>Impersonation enables or disables outbound impersonation in Hue. Principal is the Drill service principal when Kerberos authentication is enabled.</p>	<pre>options='{ "impersonation": true, "principal": "mapr/localhost@REALM" }'</pre> <pre>options='{ "impersonation": true }'</pre> <pre>options='{ "impersonation": false }'</pre>

2. Add the HTTPFS URL in hue.ini.

The `hue.ini` file contains a `[[[default]]]` section in the `[hadoop]` block under which you can see HDFS configuration options. You must uncomment an option (remove the `#` character) in the `hue.ini` file for the option to take effect.

In the `[[[default]]]` section of the `[hadoop]` block, enter the IP address of the HTTPFS node as the value for the `webhdfs_url=` option, as shown:

```
# Use WebHdfs/HttpFs as the communication mechanism.
# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://<httpfs-node-ip-address>:14000/webhdfs/v1
```

3. Start the services.

Start/Restart Hue, Drill, and HTTPS to apply the updated configurations, as shown in the following examples:

```
maprcli node services -name hue -action start -nodes
<hue-node-ip-address>

maprcli node services -name drill-bits -action start -nodes
<list-of-drill-node-ip-addresses>

maprcli node services -name httpfs -action start -nodes
<httpfs-node-ip-address>
```

Run Drill Queries in Hue

Once you have configured Hue and started the services, you can run Drill queries from Hue and visualize your data.

Complete the following steps to run Drill queries in Hue:

1. In your web browser, enter the Hue URL to navigate to the Hue web interface, as shown:

```
http://hue-node-ip-address:8888
```

2. If prompted, enter your user credentials. The Hue interface opens.
3. In the **Query** drop-down, select **Editor > Drill**. The left navigation panel displays the list of schemas available in Drill.
4. Select a schema, for example `dfs.default`, and then enter a query in the text field.
5. Click the blue play button to execute the query. Query results display.
6. Optionally, you can use the buttons to the left of the query results to visualize the data.

Configure Hue to use Drill on a Data Fabric-SASL-Secured Cluster

You can configure Hue to use Drill on a data-fabric-SASL cluster.

Procedure

1. Configure Hue to use Drill:
 - a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name="Drill"

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=MAPR-SECURITY

    # Available options:
    # "impersonation" to enable or disable outbound impersonation.
    # "principal" of Drill service. Used when Kerberos authentication
    is enabled.
    options='{ "impersonation": true, "principal": "mapr/
<node>@REALM" }'
```

- Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Configure Hue to use Drill on Kerberos-Secured Cluster

You can configure Hue to use Drill on a Kerberos-secured cluster.

Procedure

- Configure Hue to use Drill:

- In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
[[databases]]
...
[[[drill]]]

# Name to show in the UI.
nice_name="Drill"

# Database backend to use.
engine=drill

# Connection type. This can be:
# 1. direct
# 2. zookeeper
connection_type=direct

# Drillbit address for direct connection.
drillbits=<node>:31010

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
mechanism=GSSAPI

# Available options:
# "impersonation" to enable or disable outbound impersonation.
# "principal" of Drill service. Used when Kerberos authentication
is enabled.
options='{ "impersonation": true, "principal": "mapr/
<node>@REALM" }'
```

- Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Configure Hue to use Drill on PAM-Secured Cluster

You can configure Hue to use Drill on a Pluggable Authentication Modules (PAM) secured cluster.

Procedure

- Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbsms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name="Drill"

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=none

    # Username to authenticate with when connecting to the database.
    # Used with plain authentication (mechanism set to "none").
    user=<user>

    # Password matching the username to authenticate with when
    # connecting to the database.
    # Used with plain authentication (mechanism set to "none").
    password=<password>
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Configure Hue to use Drill on an Unsecured Cluster

You can configure Hue to use Drill on an unsecure cluster.

Procedure

1. Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name="Drill"

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=none
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Configure Hue to Connect to Drill Using the Drill ODBC Driver

Describes how to connect Hue to Drill using the Drill ODBC Driver.

Starting in EEP 7.0.0 (Hue 4.6.0.0 and Drill 1.16.1.0), you can install the Drill ODBC driver and then use the driver to connect Hue to Drill. Note that the Drill ODBC Driver is not available for Ubuntu.

For Hue, the ODBC Driver provides better performance than the JDBC Driver. The ODBC Driver is invoked directly from the Python VM of the Hue process whereas Hue must launch a separate Java Gateway process with the JDBC Driver to translate the Python instructions to JVM instructions, which degrades performance.

Prerequisites

Before you connect Hue to Drill:

- [Install the Drill ODBC Driver on your system.](#)
- Install the `unixODBC` package on your system:

```
yum install unixODBC
```

- (Optional) Configure the ODBC DSN (Data Source Name) in the `~/.odbc.ini` file, as described in [Apache Drill Docs: Configuring ODBC on Linux.](#)

Configuring Hue to Connect to Drill

To configure Hue to connect to Drill through the Drill ODBC Driver, add the Drill ODBC interpreter entry in the `notebook` section of `hue.ini` using the `sqlalchemy` interface, as shown in the following example:

```
[notebook]
# ...
```

```
[[interpreters]]
# ...
[[[drillodbc]]]
name=Drill ODBC
interface=sqlalchemy
## Specify Drill ODBC connection parameters separated by "&".
## Ensure that Drill ODBC drivers and unixODBC installed.
options='{ "url": "drill+odbc:///?<ODBC connection parameters>" }'
```

The following example shows a Hue configuration with the ODBC DSN (Data Source Name) configured in `~/.odbc.ini`. Note that the `DelegationUID=${USER}` property enables outbound impersonation from Hue to Drill.

```
[notebook]
# ...
[[[interpreters]]]
# ...
[[[drillodbc]]]
name=Drill ODBC
interface=sqlalchemy
options='{ "url": "drill+odbc:///?DSN=MapR Drill 64-bit&DelegationUID=${USER}" }'
```

The following example shows a Hue configuration that uses a Drillbit connection with default security (MapRSASL) enabled:

```
[notebook]
# ...
[[[interpreters]]]
# ...
[[[drillodbc]]]
name=DrillODBC
interface=sqlalchemy
options='{ "url": "drill+odbc:///?Driver=/opt/mapr/drill/lib/64/
libdrillodbc_sb64.so&ConnectionType=Direct&HOST=node1.cluster.com&PORT=31010
&AuthenticationType=MapRSASL&DelegationUID=${USER}" }'
```

NOTE: If you do not use the DSN, you must manually specify the full path to the Drill ODBC Driver, for example:

```
Driver=/opt/mapr/drill/lib/64/libdrillodbc_sb64.so
```

More information

<https://drill.apache.org/docs/odbc-configuration-reference/>

Integrate Hue With Spark

About this task

IMPORTANT: Hue integration with Spark is an experimental feature.

Procedure

1. In the [spark] section of the hue.ini file, set the livy_server_host and livy_server_port parameters to the host and port where the Livy server is running:

```
[spark]
# The Livy Server URL.
livy_server_url=https://node10.cluster.com:8998
```

2. To configure Hue to use Spark modes, modify livy.conf (vim /opt/mapr/livy/livy-<version>/conf/livy.conf):

- a) If Spark jobs run on local mode, set the livy.spark.master property:

```
...
# What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

- b) If Spark jobs run on YARN mode, set the livy.spark.master and livy.spark.deployMode properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- c) If Spark jobs run on Standalone mode, set the livy.spark.master property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = spark://ubuntu500:7077
```

- d) If Spark jobs run on Mesos mode, set the livy.spark.master property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

NOTE: Integration of Spark on Mesos with Hue is not supported in cluster deployment mode.

3. If you want to be able to access Hive through Spark in Hue, you should configure Spark with Hive, and set livy.repl.enableHiveContext to true in livy.conf. For example:

```
...
# Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
# on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

- If you are planning to use PySpark, you will need to set the PYTHONPATH environment variable in `livy-env.sh (/opt/mapr/livy/livy-<version>/conf/livy-env.sh)`:

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-<version>-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

For example:

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-0.10.7-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

- Make sure that R is installed on the node if you are planning to run SparkR. To install R to run SparkR jobs:

On Ubuntu

```
sudo apt-get install r-base
```

On Red Hat / CentOS

```
sudo yum install R
```

- Restart the Spark REST Job Server (Livy).

```
maprcli node services -name livy -action restart -nodes <livy node>
```

- Restart Hue:

```
maprcli node services -name hue -action restart -nodes <hue node>
```

Use Hue

This section provides information about using Hue, but it does not duplicate the Hue documentation.

You can also refer to the [Hue documentation](#).

This section includes the following topics:

Logging in to Hue 4.X

Once Hue is installed and the configuration files have been edited, direct your browser to the IP address where you installed Hue.

Procedure

- Open the Hue homepage: `ip_address>:8888`
The following screen appears:

Query. Explore. Repeat.

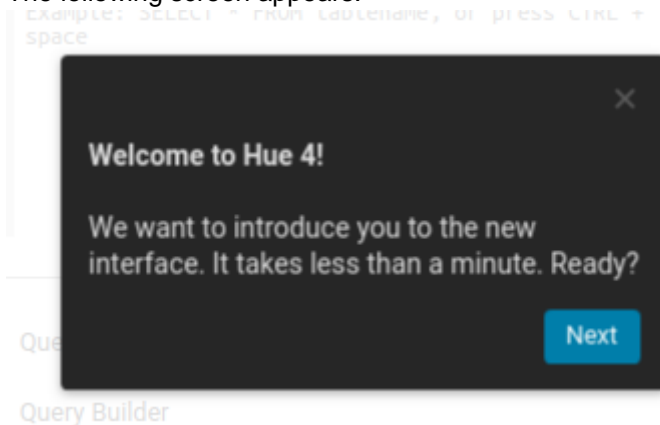

- Sign in with your username, enter the password `mapr` and click **Sign in**. You can find your username in the `/opt/mapr/conf/daemon.conf` file.

Using Hue Welcome Tour

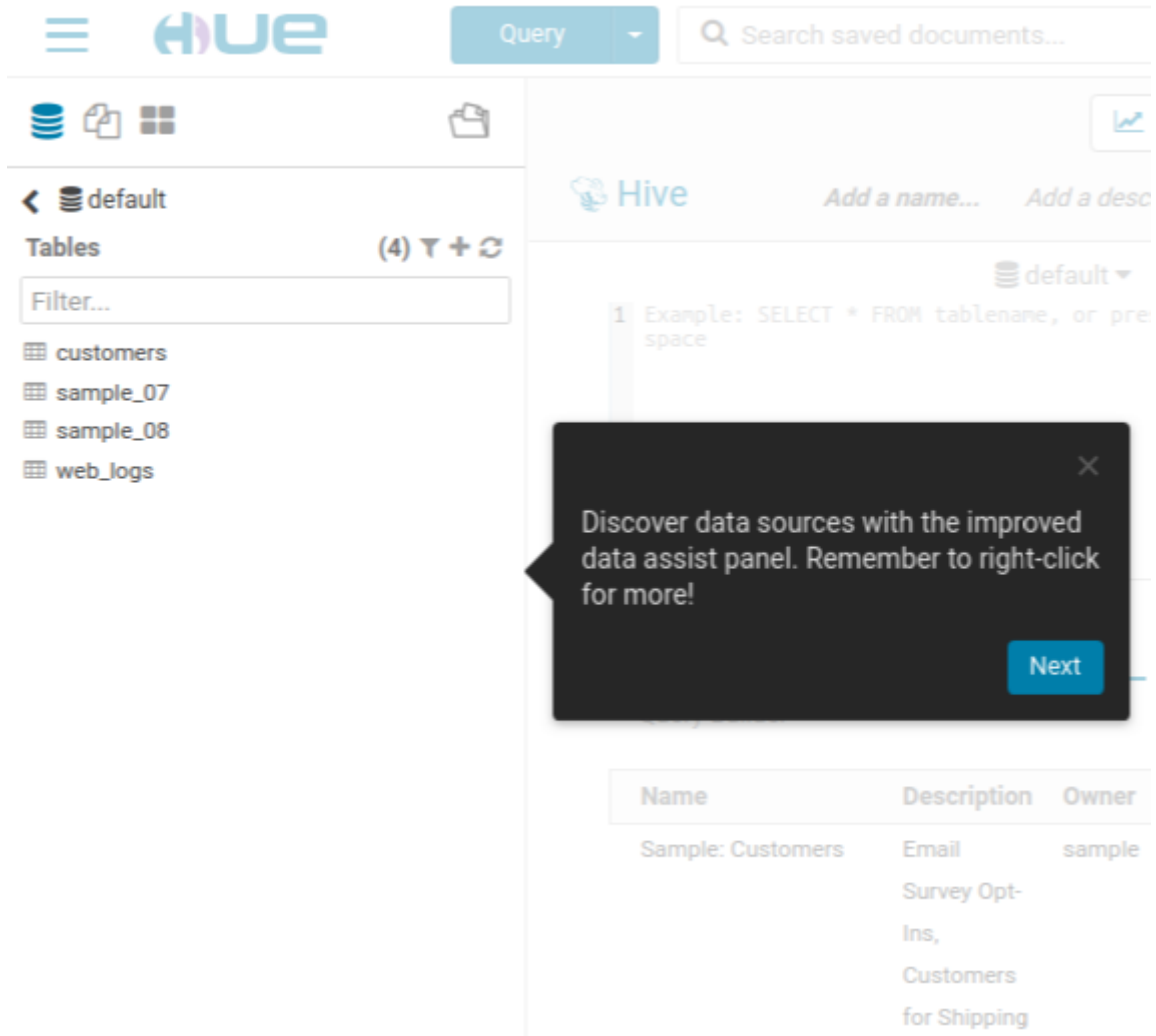

After your first login, you will be introduced to the new features in Hue 4 by the "Welcome Hue 4!" tour.

Procedure

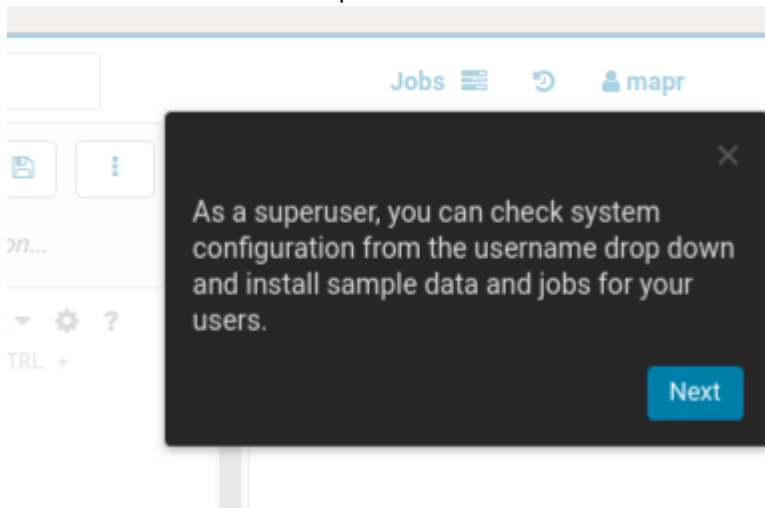

1. Start the welcome tour.
The following screen appears:

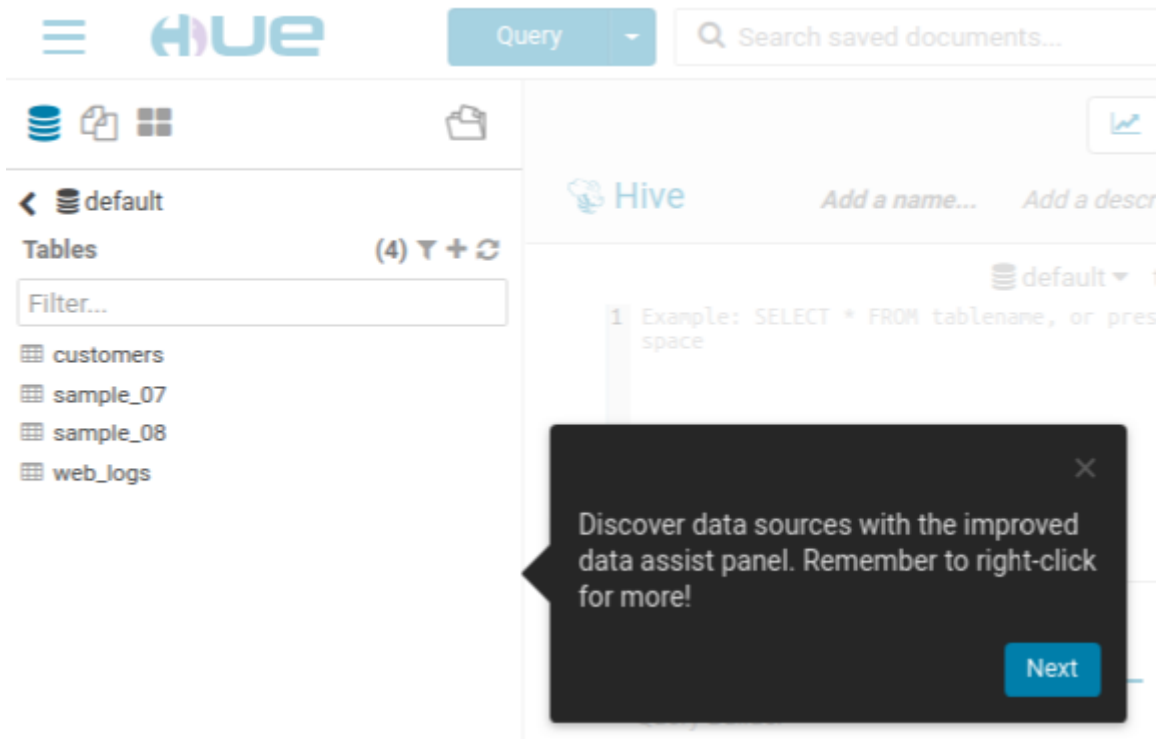

2. You are first introduced to the navigation bar:

3. You are introduced to the superuser menu:

4. You are introduced to the left assist panel:

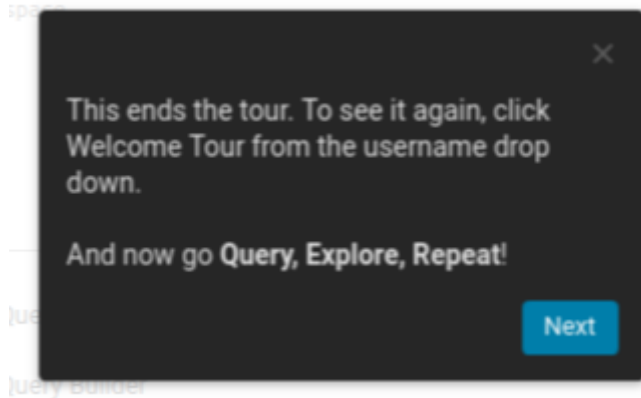

5. You are introduced to the main working zone:

6. You are introduced to the right assist panel:

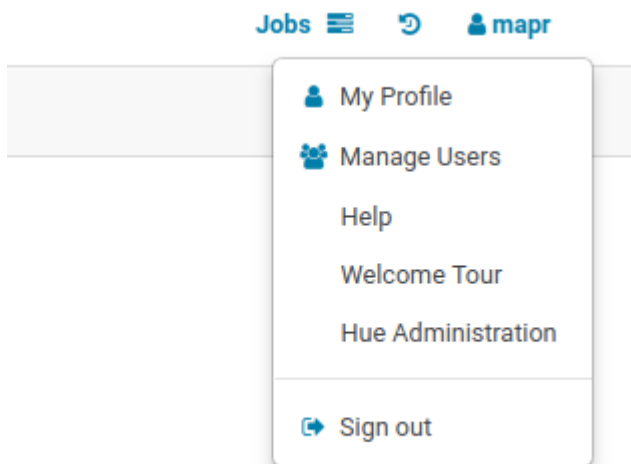

7. You then come to the end of the tour:

Getting Started with the Quick Start Wizard (Hue 4.X)

With the Quick Start Wizard you can check configuration, install examples, and create users.

Click on **Hue Administration** in the user menu:

Step 1: Check Configuration

Quick Start Wizard - Hue™ 4.2.0 - Query. Explore. Repeat.

Step 1: Check Configuration

Step 2: Examples

Step 3: Users

Step 4: Go!

Checking current configuration

Configuration files located in `/opt/mapr/hue/hue-4.2.0/desktop/conf`

All OK. Configuration check passed.

Step 2: Examples

The screenshot shows the Hue Quick Start Wizard interface. At the top, there is a navigation bar with the following items: About Hue (with a home icon), Quick start (highlighted), Configuration, Server Logs, Threads, and Metrics. Below the navigation bar, the main heading reads "Quick Start Wizard - Hue™ 4.2.0 - Query. Explore. Repeat." On the left side, there is a vertical list of steps: Step 1: Check Configuration (with a gear icon), Step 2: Examples (highlighted with a blue background and a document icon), Step 3: Users (with a group of people icon), and Step 4: Go! (with a flag icon). On the right side, under the heading "Install individual application examples", there is a list of applications with download icons: Hive, Spark, Oozie Editor/Dashboard, HBase Browser, Pig Editor, and Job Editor.

Step 3: Users

The screenshot shows the Hue Quick Start Wizard interface. At the top, there is a navigation bar with the following items: About Hue (with a home icon), Quick start, Configuration, Server Logs, Threads, and Metrics. Below the navigation bar, the main heading reads "Quick Start Wizard - Hue™ 4.2.0 - Query. Explore. Repeat." On the left side, there is a vertical list of steps: Step 1: Check Configuration (with a gear icon), Step 2: Examples (with a document icon), Step 3: Users (highlighted with a blue background and a group of people icon), and Step 4: Go! (with a flag icon). On the right side, under the heading "Create or import users", there is a list of user options: User Admin (with a person icon). Below this, under the heading "Anonymous usage analytics", there is a checkbox labeled "Help improve Hue with anonymous usage analytics." which is checked.

NOTE: By default, the Hue interface is configured to use PAM for authentication; so you cannot create or import users. For more information, see [Configure Hue Interface Authentication](#).

User Administration in Hue 4.X

By default, the Hue interface is configured to use PAM for authentication; so you cannot use the Hue interface to create users or edit their passwords.

NOTE: For more information, see [Configure Hue Interface Authentication](#).

This section contains the following topics:

Changing Your Password

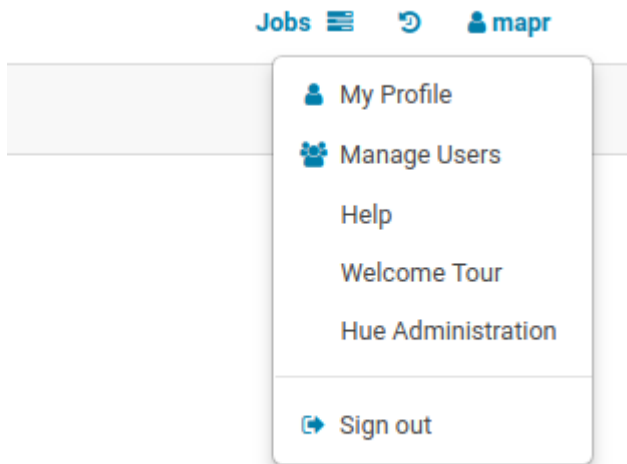

Once you log in, you can change your Hue password.

About this task

To change your Hue password, perform the following steps:

Procedure

1. Click on your **Username** at the top right of the navigation menu bar and select **Edit Profile** from the drop-down menu. In this example, the username is **mapr**.

The *Hue Users* dialog box opens.

2. Enter your current password in the *Current password* field and enter your new password in the *New Password* field. Retype the password in the *Password confirmation* field.

User Admin **Users** Groups Permissions

Hue Users - Edit user: mapr

Step 1: Credentials (required) Step 2: Names and Groups Step 3: Advanced

Username

Password

Password confirmation

Create home directory

Back Next Update user

3. Click **Update user**.

Adding Users

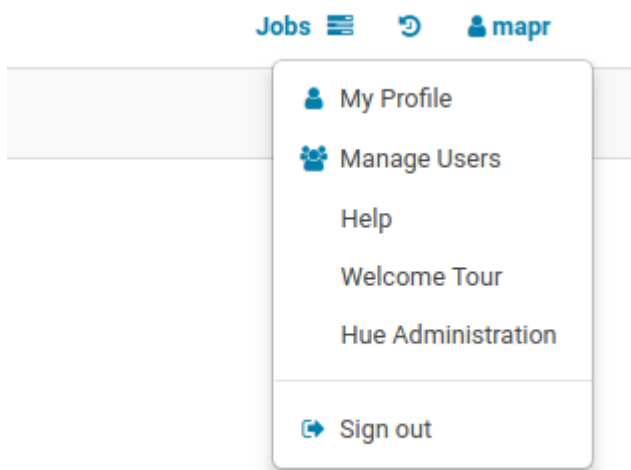

When you click on your username, all users are displayed.

About this task

To create more users, follow these steps:

Procedure

1. Click on your **Username** at the top right of the navigation menu bar and select **Manage Users** from the drop-down menu.

In this example, the username is **mapr**.

- The *Hue Users - Create user* dialog box opens.

Click **Add user** to finish the process. If you want to assign superuser privileges to the user, click **Next** to proceed to the next screen.

- Fill in the *Username*, *New Password*, and *Password confirmation* fields.
- (Optional) Fill in the user's name and email address, and assign a group.

User Admin | Users | Groups | Permissions

Hue Users - Create user

Step 1: Credentials (required) | Step 2: Profile and Groups | Step 3: Advanced

First name

Last name

Email address

Groups Select all

D

- (Optional) Assign superuser privileges to the user that you just added by checking the *Superuser status* box.

User Admin | Users | Groups | Permissions

Hue Users - Create user

Step 1: Credentials (required) | Step 2: Profile and Groups | Step 3: Advanced

Active

Superuser status

- Click **Add User**.

Managing HPE Ezmeral Data Fabric Database Binary Tables in Hue 4.X

You can create and manage HPE Ezmeral Data Fabric Database binary tables in the HBase Browser of the Hue interface.

This section includes the following sections:

Using the Hbase Browser

When you open the Hbase Browser, you can view all the directories and HPE Ezmeral Data Fabric Database binary tables available in the file system.

You can use the HBase Browser to create, edit, and search for HPE Ezmeral Data Fabric Database binary tables. However, you cannot enable, disable, or drop HPE Ezmeral Data Fabric Database binary tables.

NOTE: The browser also lists HPE Ezmeral Data Fabric Database JSON tables. However, their appearance is not different from that of HPE Ezmeral Data Fabric Database binary tables. You cannot edit JSON tables.

The screenshot displays the Hbase Browser interface. At the top, it shows 'Home - Cluster' and a 'Switch Cluster' button. Below this is a search bar labeled 'Search for Table Name', a 'Drop' button, and a '+ New Table' button. A table below the search bar has a header 'Table Name' and one row with the value 'new_table1'. Below the table, a message reads 'No data available in table'. Underneath, a directory tree is visible, starting with a root folder '/' and containing subfolders: user, oozie, tmp, opt, installer, apps, hbase, and var.

Creating a HPE Ezmeral Data Fabric Database Binary Table

You can create a new HPE Ezmeral Data Fabric Database Binary Table.

Procedure

1. In the Hbase Browser, click **New Table**.
2. In the **Table Name** field, provide the full name of the table that you want to create. For example, `my_new_table`.

Create New Table
✕

Table Name:

Column Families:

✕ somefield
➕ Add a column property

➕ Add an additional column family

Cancel
Submit

3. In the *Column Families* field, you can add column families and column properties.
4. Click **Submit**. The table that you created appears in the Hbase Browser:

Home - Cluster

Switch Cluster ▾

🗑 Drop

➕ New Table

<input type="checkbox"/> Table Name
<input type="checkbox"/> new_table1
<input type="checkbox"/> my_new_table

No data available in table

📁 /

- 📁 user
- 📁 oozie
- 📁 tmp
- 📁 opt
- 📁 installer
- 📁 apps
- 📁 hbase
- 📁 var

Starting the Hue Webserver

After you configure the `hue.ini`, you need to start the Hue Webserver and verify that it has started.

Procedure

1. To start/restart the Hue Webserver, run the following command:

- If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to start the Hue webserver:

```
maprcli node services -name hue -action start -nodes <ip_address>
```

- If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to restart the Hue webserver:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

- If Hue is installed on an edge node (not recommended), run the following command to start the Hue webserver:

```
/opt/mapr/hue/hue-<version>/bin/hue-server start
```

2. To verify that the Hue webserver started, enter: `lsof -i:8888`

The output from this command should look similar to this:

```
COMMAND      PID  USER   FD   TYPE    DEVICE  SIZE/OFF  NODE  NAME
python2.6    27688  mapr   3u   IPv4    69955314      0t0  TCP  *:ddi-tcp-1
(LISTEN)
python2.6    27691  mapr   3u   IPv4    69955314      0t0  TCP  *:ddi-tcp-1
(LISTEN)
```

You can also check Hue webserver logs to verify that Hue webserver started. If the Hue webserver was installed on a *cluster* node or an *edge* node, the log is found here:

```
/opt/mapr/hue/hue-<version>/logs/runcpserver.log
```

Livy

Apache Livy is primarily used to provide integration between Hue and Spark.

Beginning with EEP 4.0.0, Livy is included as its own package in EEP repositories. Before EEP 4.0.0, Livy was included as `mapr-hue-livy` and released only as a part of Hue. For more information about Livy, see [Apache Livy](#).

This documentation set covers the following topics for Livy:

- [Installing Livy](#) on page 214
- [Configure Livy](#) on page 4299
- [Pre-Upgrade Steps for Livy](#) on page 309
- [Upgrading Livy](#) on page 328
- [Post-Upgrade Steps for Livy](#) on page 347

Livy Limitations

This page describes some limitations of the HPE Ezmeral Data Fabric implementation of Apache Livy.

Current limitations are as follows:

- The Livy programmatic Java/Scala/Python API is not supported.
- Livy artifacts are not published in the public Maven repository with other HPE Ezmeral Data Fabric artifacts.

Configure Livy

This topic describes how to configure Livy.

For information about the required package names to configure the Livy server, see [Livy](#) on page 4298.

Configure Livy with Security

On secure clusters, data-fabric SASL authentication, encryption, and impersonation for Livy are enabled by default.

The Livy user interface is available on port 8998. To start the user interface, open a browser, and navigate to the following address:

```
https://<hostname>:8998
```

Configure Livy on Kerberos

This topic describes how to configure Livy on Kerberos.

To configure Livy on Kerberos, add the following properties to the `livy.conf` file:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/_HOST@HADOOP.LOCALDOMAIN
livy.server.auth.kerberos.keytab = $KEYTAB
livy.server.launch.kerberos.principal = $USER/_HOST@HADOOP.LOCALDOMAIN
livy.server.launch.kerberos.keytab = $KEYTAB
```

For example:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/node2.cluster@NODE1
livy.server.auth.kerberos.keytab = /opt/mapr/conf/mapr.keytab
livy.server.launch.kerberos.principal = mapr/node2.cluster@NODE1
livy.server.launch.kerberos.keytab = /opt/mapr/conf/mapr.keytab
```

Livy UI on Kerberos

NOTE: You can login to the Livy UI on a Kerberos setup only using a web browser configured with SPNEGO.

The other option is to configure multiauth authentication on Kerberized configurations to allow you to login to Livy UI not only with SPNEGO/Mapr-Negotiation mechanisms but also with PAM credentials.

Configure Livy with Custom SSL Encryption

This topic describes how to configure Livy with custom SSL encryption.

Procedure

1. By default, on a secure cluster, Livy reads the `ssl-server.xml` file and configures SSL from this file.

- If you want to use custom SSL configuration, add the following properties to the `livy.conf` file:

```
## Use this keystore for the SSL certificate and key.
livy.keystore = <path-to-ssl_keystore>

# Specify the keystore password.
livy.keystore.password = <password>

# Specify the key password.
livy.key-password = <password>
```

Configure Livy with Spark Modes

This topic describes how to configure Livy with different Spark modes.

Use these steps to configure Livy:

- Modify the `livy.conf` file (`/opt/mapr/livy/livy-<version>/conf/livy.conf`):
 - If Spark jobs run in local mode, set the `livy.spark.master` property:

```
...
# What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

- If Spark jobs run in YARN mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- c. If Spark jobs run in Standalone mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- d. If Spark jobs run in Mesos mode, set the `livy.spark.master` property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

2. To you want to use impersonation with Livy, set `livy.impersonation.enabled` to `true` in `livy.conf`. For example:

```
# If livy should impersonate the requesting users when creating a new
session.
livy.impersonation.enabled = true
```

3. If you want to be able to access Hive through Spark for Livy, you should configure Spark with Hive, and set `livy.repl.enableHiveContext` to `true` in `livy.conf`. For example:

```
...
# Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
# on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

NOTE: If Hive is installed on a cluster and if Spark is configured on Hive, this property is set to true by default: `livy.repl.enableHiveContext = true`.

4. To apply the needed changes, restart the Livy service:

```
maprcli node services -name livy -action restart -nodes <livy node>
```

HPE Ezmeral Data Fabric Streams Clients and Tools

Describes the supported HPE Ezmeral Data Fabric Streams tools and clients.

HPE Ezmeral Data Fabric Streams Tools

Starting in EEP 8.0.0 and Core 6.2, Kafka 2.6.1.0 supports the following tools and components:

- Kafka Streams API 1.1
- KSQL 6.0.0.0
- Kafka REST 6.0.0.0
- Kafka Connect 10.0.0.0
- Kafka Schema Registry 6.0.0.0
- Spark Streaming

For a complete list of supported versions in each EEP, see [Component Versions for Released EEPs](#) on page 6600.

The following points describe the Kafka tools and provide links to additional information:

- [Kafka Streams](#) on page 4320: This tool is a programming library used for creating Java or Scala streaming applications.
- [KSQL](#) on page 4302: This tool is an open source streaming SQL engine that implements continuous, interactive queries.
- [Kafka Schema Registry](#): This tool provides a RESTful interface for storing and retrieving Avro schemas.
- [Kafka REST Proxy](#) on page 4331: This tool is used as a RESTful interface to HPE Ezmeral Data Fabric Streams.
- [Kafka Connect](#) on page 4371: This tool is used to stream data between HPE Ezmeral Data Fabric Streams and other storage systems.

HPE Ezmeral Data Fabric Streams Clients

HPE Ezmeral Data Fabric Streams client applications can be developed for HPE Ezmeral Data Fabric Streams (as of MapR 5.2.1 with EEP 3.0). The HPE Ezmeral Data Fabric Streams clients are based on distributions of librdkafka that works with HPE Ezmeral Data Fabric Streams.

- HPE Ezmeral Data Fabric Streams C Client - Used to develop HPE Ezmeral Data Fabric Streams applications in C. See [HPE Ezmeral Data Fabric Streams C Applications](#) on page 3434
- HPE Ezmeral Data Fabric Streams Java Client - Used to develop HPE Ezmeral Data Fabric Streams applications in Java. See [HPE Ezmeral Data Fabric Streams Java Applications](#) on page 3395
- HPE Ezmeral Data Fabric Streams Python Client - Used to develop HPE Ezmeral Data Fabric Streams applications in Python. This client is available as of MapR 5.2.1 with EEP 3.0. See [HPE Ezmeral Data Fabric Streams Python Applications](#) on page 3637

Table

MapR release	EEP Release	Kafka librdkafka version
As of MapR 6.0.1	As of 5.0	0.11.3

KSQL

KSQL is an open-source streaming SQL engine that implements continuous, interactive queries.

Use KSQL to query, read, write, and process data in real-time, at scale, through SQL commands. KSQL interacts directly with the [Kafka Streams API](#), eliminating the need for a Java application.

The KSQL data flow architecture is designed such that the user interacts with the KSQL server and the KSQL server interacts with the HPE Ezmeral Data Fabric Streams server.

Use Cases

Common use cases include fraud detection, personalization, notifications, real-time analytics, and sensor data and IoT.

Architecture

A set of KSQL processes run as a cluster, and the KSQL server process completes queries. You can dynamically add more processing capacity by starting more instances of the KSQL server. These instances are fault-tolerant: if one fails, the others continue the work. Queries are launched using the interactive KSQL command line client, which sends commands to the cluster over a REST API. The command line allows you to inspect the available streams and tables, issue new queries, check the status of and terminate running queries.

KSQL Server

The KSQL server runs the engine that completes KSQL queries. This includes processing, reading, and writing data to and from the target Kafka cluster. KSQL servers form KSQL clusters and can run in containers, virtual machines, and bare-metal machines. You can add and remove servers in a KSQL cluster during live operations to elastically scale processing capacity. You can deploy different KSQL clusters to achieve workload isolation.

KSQL CLI

You can interactively write KSQL queries through the KSQL command line interface (CLI). The KSQL CLI acts as a client to the KSQL server.

KSQL Deployment Modes

You can deploy KSQL queries through Interactive or Non-Interactive mode.

Interactive Mode

In Interactive mode, users interact with the KSQL server through a REST API, such as the KSQL CLI. Interactive mode is useful when users need to write and verify their queries interactively on a shared KSQL cluster. In interactive KSQL clusters, the authenticated KSQL user must have open access to create, read, write, delete topics, and use of any consumer group.

Starting in EEP 7.0.0 (Core 6.2.0 and KSQL 5.2.1.0), Interactive mode is recommended for production.

Non-Interactive Mode (Headless Mode)

Non-interactive mode supports locked-down or “headless” deployment scenarios where interactive use of the KSQL cluster is disabled, thereby preventing KSQL CLI access. In this mode, you can write queries to an SQL file, which allows for version control, and lock down access to KSQL servers to prevent users from interacting directly with the KSQL cluster.

KSQL Security

By default, KSQL is secured when installed on secured clusters (clusters secured by the data fabric ticket-based security). See [KSQL Security](#) on page 4304 for additional information.

For More Information

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)
- [Apache Kafka Streams](#)

KSQL Security

Discusses KSQL security topics.

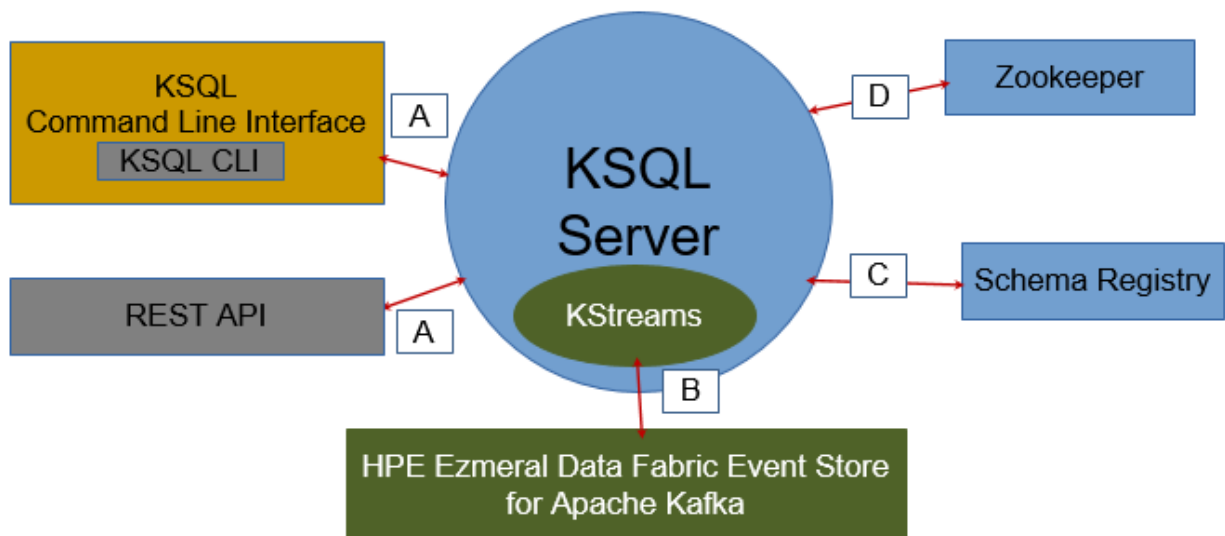

KSQL Security Overview

By default, KSQL is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, impersonation, and authorization. For encryption, SSL/TLS protocols are supported.

If you install KSQL in an insecure cluster, you can enable security through security parameters in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file, as described in [KSQL Security Parameters](#).

KSQL Communication Paths

The following image depicts the KSQL communication paths:

The following table lists the supported security mechanisms for the KSQL communication paths:

NOTE: Path B does not have a network connection and therefore does not need to be secured. However, impersonation works for this path through KSQL Server.

Security Features	Supported Mechanisms	Communication Paths Secured
Authentication	Data Fabric SASL (ticket-based security)	D - KSQL Server and ZooKeeper
		A - KSQL client (KSQL CLI/REST API) and KSQL server
		C - KSQL Server and Schema Registry
	Basic (PAM)	A - KSQL client (KSQL CLI/REST API) and KSQL server
		C -KSQL Server and Schema Registry
	Cookie	A - KSQL client (KSQL CLI/REST API) and KSQL server
	C - KSQL Server and Schema Registry	
Encryption	Data Fabric SASL (ticket-based security)	D - KSQL Server and ZooKeeper
		A - KSQL client (KSQL CLI/REST API) and KSQL server
		C -KSQL Server and Schema Registry
	SSL/TLS	A - KSQL client (KSQL CLI/REST API) and KSQL server
		C - KSQL Server and Schema Registry
Authorization	Based on filesystem permissions	A - KSQL client (KSQL CLI/REST API) and KSQL server
Impersonation	User impersonation	A - KSQL client (KSQL CLI/REST API) and KSQL Server
		B - KSQL Server to Streams for Apache Kafka
		C - KSQL Server and Schema Registry
Auditing	Not supported	--

Impersonation

See [KSQL Impersonation](#) on page 4308.

Authorization

See [KSQL Authorization](#) on page 4307.

Authenticating to KSQL

To authenticate to the KSQL server from the KSQL CLI, include the `--auth` flag and indicate the authentication type for your KSQL environment, for example:

```
ksql --auth MAPRSASL http://<ip-address>:8084

//Note that 8084 is the default port for KSQL.
```

On a secure cluster, the default value for `--auth` is MAPRSAL. On an insecure cluster, the default value is NONE. The `--auth` flag accepts the following values:

- `--auth BASIC` (For basic or PAM, the system prompts users for a username and password.)
- `--auth MAPRSASL` (For `maprsasl`, a `mapr` user ticket is used.)
- `--auth NONE` (For none, authentication is disabled.)

To connect the KSQL client to a KSQL server running in a remote cluster, include the `--cluster` option with the remote cluster name, as shown:

```
ksql --cluster my.mapr.cluster https://<ip-address>:8084
```

KSQL COMMANDS

The KSQL COMMANDS internal topic is used to backup information about KSQL streams, KSQL tables, KSQL persistent queries, and so on. KSQL uses KSQL COMMANDS to restore the KSQL server state in case there is a fault or server restart.

Each KSQL Server cluster has a unique service ID which is provided through the `ksql.service.id` property. By default, the `ksql.service.id` is `_default`. To provide additional security, `ksql.service.id`-specific folders are created in the `ksql-internal-stream` stream.

NOTE: The `/apps` directory has only write access to `mapr` user. Therefore, the `/apps/ksql` directory cannot be modified or deleted by any user other than `mapr` user.

KSQL `ksql.service.id`-specific folders are created in the `/apps/ksql/` directory for every KSQL server cluster (represented by `ksql.service.id`).

Default Stream

KSQL Server provides a default stream for topics when they are being processed. When KSQL Server is not impersonated (non-interactive or interactive+no-impersonation), the KSQL Server default stream is used.

KSQL Cleanup

The KSQL cleanup feature is integrated to ensure that the underlying KSQL state (such as internal topics) are cleaned up correctly. See [Application Reset Tool](#) on page 4326 for more information.

Deployment

The Warden service (`mapr-warden`) manages KSQL Servers in clusters.

NOTE: A service ID (`ksql.service.id`) is uniquely created for the KSQL implementation; this means that the user associated with the `service ID` cannot grant permissions to other users to use the same service ID.

Cookie Authentication for KSQL

User credentials or challenge strings use cookies to sign requests. After cookies are received on the client side, user credentials or challenge strings are erased from memory. For KSQL, when cookies expire, you have to login again to get the new cookies. Default expiration time for cookies is one week.

Specify a Custom KSQL Truststore Location on a Secure Cluster

By default, the KSQL CLI uses the truststore file located in `/opt/mapr/conf/ssl_truststore` on a secure cluster; however, you can specify a custom SSL truststore file location through properties set from the command line or in the `ksql-server.properties` file.

Use the Default Truststore File

To use the default truststore file while working in the KSQL CLI, run:

```
ksql https://node1.cluster.com:8084
```

Specify a Custom KSQL Truststore from the Command Line

Use the `--truststore` flag with the directory location where the SSL truststore file is located and the `--truststore-password` with the truststore password, as shown in the following example:

```
ksql https://
node1.cluster.com:8084 --truststore /o
pt/mapr/conf/
ssl_truststore2 --truststore-password
test123
```

For More Information

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)

KSQL Authorization

Describes authorization for Kafka KSQL.

In secure clusters, authorization is enabled by default. In insecure clusters, authorization is disabled by default.

You can enable or disable authorization for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
authorization.enable=[true|false]
```

Permissions

Permissions grant or deny access to users that run commands and maintain background processes that interact with KSQL internal data and structure information, such as persistent queries, tables, streams, and server configuration. *Read* permission grants users and groups access to `FETCH`, `SHOW`, and `DESCRIBE`. *Modify* permission grants users and groups access to `ADD`, `UPDATE`, and `REMOVE`.

Each user or group in a cluster can have no permissions, *read* permission, *modify* permission, or both *read* and *modify* permission to the KSQL service. By default all data-fabric cluster users have both *read* and *modify* permissions.

Internally, the authorization filter is based on *consumeperms* and *produceperms* for the KSQL Kafka store internal stream (`/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`). *Consumeperms* correspond to the KSQL service *read* permissions. *Produceperms* correspond to the KSQL service *modify* permissions. These permissions can be changed by modifying the ACE of *produceperms* and *consumeperms* for `/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`.

The following sections describe KSQL statements that require *read* and *modify* access.

Statements that Require Read Access**DESCRIBE [EXTENDED] ...**

List the columns in a stream or table along with its attributes and information.

DESCRIBE FUNCTION ...	Provides a description of a function including an input parameters and the return type.
EXPLAIN ...	Show the execution plan for a SQL expression or, given the ID of a running query, show the execution plan plus additional runtime information and metrics.
PRINT ...	Print the contents of Kafka topics to the KSQL CLI.
SELECT ...	Selects rows from a KSQL stream or table.
SHOW ...	List functions, streams, tables, queries, properties.
SHOW TOPICS <MAPR_STREAM>	List topics.

Statements that Require Modify Access

CREATE STREAM TABLE ... WITH (...)	Create a new stream or table with the specified columns and properties.
CREATE STREAM TABLE ... [WITH (...)] AS SELECT ...	Create a new stream or table and continuously write the result of the SELECT query into the stream.
INSERT INTO ... SELECT ...	Stream the result of the SELECT query into an existing stream and its underlying topic.
INSERT INTO ... VALUES ...	Produce a row into an existing stream or table and its underlying topic based on explicitly specified values.
DROP STREAM TABLE [IF EXISTS] ...	Drops an existing stream or table.
DROP STREAM TABLE [IF EXISTS] ... DELETE TOPIC	Drops an existing stream or table and deletes the underlying topic.
TERMINATE ...	Terminate a persistent query.

KSQL Impersonation

Describes impersonation for Kafka KSQL.

The HPE Ezmeral Data Fabric Event Store implementation performs impersonation on behalf of KSQL CLI users in KSQL Servers. Impersonation authorizes the impersonated user to perform permission-sensitive operations. In secure clusters, impersonation is enabled by default. In insecure clusters, impersonation is disabled by default.

Requirement: For impersonation to work, KSQL authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands run as the authenticated user instead of the KSQL principal. The KSQL principal is the user that started KSQL server.

You can enable or disable impersonation for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
impersonation.enable=[true|false]
```

Related concepts

[KSQL Authorization](#) on page 4307

Describes authorization for Kafka KSQL.

KSQL Configuration

Set KSQL configuration and security parameters in the `ksql-server.properties` file. The default port for KSQL is 8084.

Configuring KSQL to Run in Non-Interactive (Headless) Mode

To run KSQL in non-interactive mode, set the parameters shown and then start KSQL.

 **NOTE:** Note that the `ksql.default.stream` parameter is optional, but recommended. This parameter sets the default stream to consume from and send the messages to. The default stream is used if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message is sent to `exampleStream:exampleTopic`.

Set the following properties in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://localhost:8084
ksql.default.stream=/sample-stream
```

Start KSQL:

```
$ KSQL_INSTALL_DIR/bin/ksql-server-start /opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties --queries-file some-queries-file.sql
```

Configuring KSQL to Run in Interactive Mode

The following example shows the configuration parameters that you must set in the `ksql-server.properties` file to run KSQL in interactive (distributed) mode:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://192.168.121.73:8084
ksql.default.stream=/sample-stream
```

 **NOTE:** You must set the `listeners` parameter to an actual IP address.

For more information

- For installation information, see [Installing KSQL](#) on page 204.
- For Apache Kafka information, see the [Apache Kafka Streams API](#), [Apache Kafka Producer Clients](#), and the [Apache Kafka Consumer Clients](#).

KSQL Configuration Parameters

Set the KSQL configuration parameters in the `/opt/mapr/ksql/ksql-<version>/config/ksql-server.properties` file. For more information about configuration parameters, see [KSQL Configuration Parameter Reference](#).

The following table describes some KSQL configuration parameters:

Parameter	Description
<code>ksql.default.stream</code>	The stream that is used when a topic is used without a stream name.
<code>ksql.schema.registry.enable</code>	Flag for enabling Avro format support with Schema Registry. Default value: false
<code>ksql.schema.registry.service.id</code>	Indicates the ID of the schema registry service. Default value: default_
<code>ksql.schema.registry.discovery.timeout</code>	The timeout (in milliseconds) for requests to Schema Registry URL storage. Default value: 60000
<code>ksql.schema.registry.discovery.retries</code>	The number of retries for Schema Registry URL discovery. Default value: 6

Parameter	Description
ksql.schema.registry.discovery.interval	The interval (in milliseconds) between retries for Schema Registry URL discovery. Default value: 15000

KSQL Security Parameters

Describes KSQL security parameters.

Security parameters provide an authentication, encryption, and impersonation layer between the KSQL clients and the KSQL Server. In secure clusters, KSQL is secured by default. In insecure clusters, you can enable security through the security parameters in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file.

Requirement: Before you configure KSQL security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table describes KSQL security parameters:

Parameter	Description	Type	Default
ksql.schema.registry.maprsasl.auth	Enable MapR Sasl authentication for Avro format with Schema Registry.	boolean	false
authentication.cookie.expiration	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
authorization.enable	Set 'true' or 'false' to enable or disable authorization for KSQL service. See KSQL Authorization on page 4307.	boolean	false
authentication.enable	Whether or not to enable authentication.	boolean	false
impersonation.enable	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See KSQL Impersonation on page 4308.	boolean	false
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: http://localhost:8084	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> • TLS_DHE.* • TLS_EDH.* • .DES. • .MD5. • .RC4.
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. <i>This option is not available in KSQL 6.0.</i>	boolean	false
ssl.client.authentication	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. Possible values are NONE, REQUESTED, and REQUIRED. <i>This option is available in KSQL 6.0.</i>	string	none

Parameter	Description	Type	Default
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> SSLv3 TLSv1.0
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.  NOTE: If the <code>ssl-client.xml</code> file is changed, restart KSQL.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	empty
ssl.keystore.location	Location of the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.  NOTE: If the <code>ssl-client.xml</code> file is changed, restart KSQL.	string	empty
ssl.keystore.password	The store password for the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.  NOTE: If the <code>ssl-client.xml</code> file is changed, restart KSQL.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the <code>SslContextFactory</code> .	string	TLS
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false

Parameter	Description	Type	Default
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

Related reference

[KSQL Security](#) on page 4304

Discusses KSQL security topics.

KSQL Reference

KSQL-specific commands are commands for setting your KSQL configuration, exiting the CLI, and so on.

Run the KSQL with `--help` to see the available options.

```
./bin/ksql --help
```

CLI commands include:

- help
- clear
- output
- output <format>
- history
- version
- exit

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

*KSQL Statements***General Syntax**

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

KSQL statements must be terminated with a semicolon (;).

For multi-line statements:

- In the CLI, you use a back-slash (\) to indicate continuation of a statement on the next line.
- Do not use backslashes (\) for multi-line statements in .sql files.

CREATE STREAM**CREATE STREAM WITH clause**

Creates a new stream with the specified columns and properties.

```
CREATE STREAM stream_name ( { column_name data_type } [, ...] )
  WITH ( property_name = expression [, ...] );
```

CREATE STREAM WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding HPE Ezmeral Data Fabric Streams topic.

```
CREATE STREAM stream_name
  [WITH ( property_name = expression [, ...] )]
  AS SELECT select_expr [, ...]
  FROM from_item [, ...]
  [ WHERE condition ]
  [ PARTITION BY column_name ]
```

CREATE TABLE**CREATE TABLE WITH clause**

Creates a new KSQL table with the specified columns and properties.

```
CREATE TABLE table_name ( { column_name data_type } [, ...] )
  WITH ( property_name = expression [, ...] );
```

CREATE TABLE WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding HPE Ezmeral Data Fabric Streams topic and stream.

```
CREATE TABLE table_name
  [WITH ( property_name = expression [, ...] )]
  AS SELECT select_expr [, ...]
  FROM from_item [, ...]
  [ WINDOW window_expression ]
  [ WHERE condition ]
  [ GROUP BY grouping_expression ]
  [ HAVING having_expression ];
```

DESCRIBE**DESCRIBE**

Lists the columns in a stream or table along with their data type and other attributes.

```
DESCRIBE (stream_name|table_name);
```

DESCRIBE EXTENDED

Displays DESCRIBE information with additional runtime statistics, HPE Ezmeral Data Fabric Streams topic details, and the set of queries that populate the table or stream.

```
DESCRIBE [EXTENDED] (stream_name|table_name);
```

EXPLAIN**EXPLAIN**

Shows the execution plan for a SQL expression or, given the ID of a running query, shows the execution plan plus additional runtime information and metrics.

```
EXPLAIN (sql_expression|query_id);
```

DROP STREAM

DROP STREAM

Drops an existing stream

```
DROP STREAM stream_name;
```

DROP TABLE

DROP TABLE

Drops an existing table.

```
DROP TABLE table_name;
```

PRINT

PRINT

Prints topic contents to the KSQL CLI.

NOTE: SQL grammar defaults to uppercase formatting. To print topics containing lower-case characters, use quotations.

```
PRINT qualified_name (FROM BEGINNING)? ((INTERVAL | SAMPLE) number)?
```

Print Example

```
ksql> print '/sample-stream:streams-pipe-input' FROM BEGINNING;
Format:STRING
3/16/18 1:04:39 AM EET , 1 , record1
3/16/18 1:04:39 AM EET , 5 , record5
3/16/18 1:04:39 AM EET , 6 , record6
3/19/18 4:22:51 PM EET , null , Hello
3/19/18 4:23:05 PM EET , null , Hello2
```

SELECT

SELECT

Selects rows from a KSQL stream or table. The result of this statement is not persisted in a topic and is only printed out in the console. To stop the continuous query in the CLI press Ctrl-C.

Example for KSQL 5.x:

```
SELECT select_expr [, ...] FROM from_item [, ...] [ WINDOW
window_expression ] [ WHERE condition ] [ GROUP BY grouping_expression ]
[ HAVING
having_expression ];
```

Example for KSQL 6.0 or later:

```
SELECT select_expr [, ...]
FROM from_item
[ LEFT JOIN join_table ON join_criteria ]
[ WINDOW window_expression ]
[ WHERE condition ]
[ GROUP BY grouping_expression ]
```

```
[ HAVING having_expression ]
EMIT CHANGES
[ LIMIT count ];
```

SELECT CAST expression type

Casts an expression's type to a new type.

```
CAST (expression AS data_type);
```

Example to convert BIGINT to VARCHAR type for KSQL 5.x:

```
SELECT page_id, CONCAT(CAST(COUNT(*) AS VARCHAR), '_HELLO')
FROM pageviews_enriched
WINDOW TUMBLING (SIZE 20 SECONDS)
GROUP BY page_id;
```

Example to convert BIGINT to VARCHAR type for KSQL 6.0 or later:

```
SELECT userid, CONCAT(CAST(COUNT(*) AS VARCHAR), '_HELLO')
FROM pageviews
WINDOW TUMBLING (SIZE 20 SECONDS)
GROUP BY userid
EMIT CHANGES;
```

SELECT LIKE operator

The LIKE operator is used for prefix or suffix matching. Currently KSQL supports %, which represents zero or more characters.

```
column_name LIKE pattern;
```

Example for KSQL 5.x:

```
SELECT user_id
FROM users
WHERE user_id LIKE 'santa%';
```

Example for KSQL 6.0 or later:

```
SELECT userid
FROM pageviews
WHERE userid LIKE '%4'
EMIT CHANGES;
```

SHOW TOPICS

SHOW TOPICS

Prints topic information for all topics for the default stream (specified by `ksql.default.stream`). If the default stream is not specified, then an exception is thrown.

```
SHOW TOPICS;
```

SHOW TOPICS <stream_name>

Prints topic information for all topics from the specified stream. For example: /sample-stream

```
SHOW TOPICS '/sample-stream';
```

SHOW STREAMS**SHOW STREAMS**

List the defined streams.

```
SHOW | LIST STREAMS;
```

SHOW TABLES**SHOW TABLES**

List the defined TABLES.

```
SHOW | LIST TABLES;
```

SHOW QUERIES**SHOW QUERIES**

List the running persistent queries.

```
SHOW | LIST QUERIES;
```

SHOW PROPERTIES**SHOW PROPERTIES**

Lists the configuration setting that are currently in effect.

```
SHOW PROPERTIES;
```

TERMINATE**TERMINATE**

Terminate a persistent query. Persistent queries run continuously until they are explicitly terminated

```
TERMINATE query_id;
```

Scalar Functions

The following are scalar functions for KSQL.

Table

Function	Example	Description
ABS	ABS(col1)	Absolute value of a value.
CEIL	CEIL(col1)	Ceiling of a value.
CONCAT	CONCAT(col1, '_hello')	Concatenate two strings.
EXTRACTJSONFIELD	EXTRACTJSONFIELD(message, '\$.log.cloud')	Given a string column in JSON format, extract the field that matches.

Table (Continued)

Function	Example	Description
ARRAYCONTAINS	ARRAYCONTAINS(['1, 2, 3'], 3)	Given a JSON or AVRO array, checks if a search value is contained in it.
FLOOR	FLOOR(col1)	Floor of a value.
LCASE	LCASE(col1)	Convert a string to lowercase.
LEN	LEN(col1)	Length of a string.
RANDOM	RANDOM()	Returns a random DOUBLE value between 0 and 1.0
ROUND	ROUND(col1)	Round a value to the nearest BIGINT value.
STRINGTOTIMESTAMP	STRINGTOTIMESTAMP(col1, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a string value in the given format into the BIGINT value representing the timestamp.
SUBSTRING	SUBSTRING(col1, 2, 5)	Returns the substring with the start and end indices.
TIMESTAMP TO STRING	TIMESTAMP TO STRING(ROWTIME, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a BIGINT timestamp value into the string representation of the timestamp in the given format.
TRIM	TRIM(col1)	Trim the spaces from the beginning and the end of the string.
CASE	CASE(col1)	Convert a string to uppercase.

Aggregate Functions

The following are aggregate functions for KSQL.

Table

Function	Example	Description
COUNT	COUNT(col1)	Counts the number of rows.
MAX	MAX(col1)	Returns the maximum value for a given column and window.
MIN	MIN(col1)	Returns the minimum value for a given column and window.
SUM	SUM(col1)	Sums the column values.
TOPK	TOPK(col1, K)	Returns the TopK values for the given column and window.
TOPKDISTINCT	TOPKDISTINCT(col1, K)	Returns the distinct TopK values for the given column and window.

Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves an inputTopic to an outputTopic:

```
ksql> CREATE STREAM stream3 (message varchar) WITH (kafka_topic='sample-stream:inputTopic', value_format='DELIMITED');

ksql> CREATE STREAM stream4 WITH (kafka_topic='/'
```

```
sample-stream:streams-pipe-output1', value_format='DELIMITED') AS SELECT *
FROM stream3;
```

KSQL Demo

The following demo example creates a stream, performs a non-persistent query, and a persistent query.

Setup

Complete the following steps to prepare your environment for querying:

1. Create a default stream using `/sample-stream`:

```
maprcli stream create -path /sample-stream
                    -produceperm p -consumeperm p -topicperm p
```

2. Run the following script to generate test data that writes to an HPE Ezmeral Data Fabric Streams topic:

```
./bin/ksql-datagen quickstart=pageviews format=delimited
topic=/sample-stream:pageviews maxInterval=10000
```

3. Run KSQL CLI and create a KSQL table:

```
> ./bin/ksql http://<ksql-server>:8084
ksql> CREATE TABLE pageviews_original_table (viewtime bigint
primary key, userid varchar, pageid varchar) WITH (kafka_topic='/
sample-stream:pageviews', value_format='DELIMITED');
```

ATTENTION: Note the following for KSQL 6.0:

- A table created on top of a Kafka topic does not materialize into a view because queries on such tables would be highly inefficient.
- KSQL does not support pull queries on tables created by the `CREATE TABLE` command; however, you can issue pull queries against tables created by the `CREATE TABLE AS SELECT` statement.

```
ksql> CREATE STREAM pageviews
      (viewtime BIGINT,
       userid VARCHAR,
       pageid VARCHAR)
      WITH (KAFKA_TOPIC='/sample-stream:pageviews',
           VALUE_FORMAT='DELIMITED');
```

```
ksql> CREATE TABLE PAGEVIEWS_TABLE
      WITH(KAFKA_TOPIC='/sample-stream:pageviews_table')
      AS
      SELECT userid,
             MAX(viewtime)
      FROM pageviews
      GROUP BY userid;
```

4. Run the `SHOW TABLES` command to list your KSQL tables:

```
ksql> SHOW TABLES;
```

Run a Non-persistent Query

For a non-persistent query, run:

```
ksql> SELECT * FROM pageviews_original_table;
```

For a non-persistent query in KSQL 6.0, run:

```
ksql> SELECT * FROM PAGEVIEWS_TABLE WHERE userid='User_1';
```

Run a Persistent Query

For a persistent query, do the following:

1. Create the topic, /sample-stream:input-topic:

```
maprcli stream topic create -path /sample-stream -topic input-topic
```

2. Create a KSQL input stream:

```
ksql> CREATE STREAM stream1 (message varchar) WITH
      (kafka_topic='/sample-stream:input-topic' ,
      value_format='DELIMITED');
```

3. Create persistent query with filtering:

```
ksql> CREATE STREAM stream2
      WITH (kafka_topic='/sample-stream:output-topic' ,
      value_format='DELIMITED')
      AS SELECT * FROM stream1 WHERE LEN(message) > 2;
```

4. List your queries:

```
ksql> SHOW QUERIES;
```

5. Run the provided sample code for the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092 --topic /sample-stream:input-topic
```

6. Run the provided sample code for the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:output-topic
```

7. Produce some data:

```
>Hi
>Hello
>No
>Yes
```

8. Get the next results:

```
Hello  
Yes
```

Auxiliary Scripts Location

The sample code for `kafka-console-producer.sh` and `kafka-console-consumer.sh` is packaged with MapR Kafka. Once MapR Kafka is installed, you can find them at:

```
/opt/mapr/kafka/kafka-<version>/bin/
```

Kafka Streams

Kafka Streams is a programming library used for creating Java or Scala streaming applications and, specifically, building streaming applications that transform input topics into output topics.

Kafka Streams allows you to build moderately complex operational streaming applications faster by offloading common functions such as failure recovery, joins and enrichment, and aggregations and windowing.

Kafka Streams application is a distributed Java application that is launched with one or more Kafka Streams application instances. Kafka Streams applications can be built using the KStream library. A KStream application instance is required to be provided with an `application.id` property. The `application.id` property uniquely identifies the Kafka Streams distributed application.

 **ATTENTION:** The Kafka Streams application must always be launched as the same user.

Architecture

An application that uses the Kafka Streams API is a normal Java application. Package, deploy, and monitor it like you would do for any other Java application. There is no need to install separate processing clusters or similar special-purpose and expensive infrastructure.

 **NOTE:** You can run one or more instances of your application. They run independently but will automatically discover each other and collaborate. In addition, you can elastically add and remove application instances during live operations. If one instance dies, another instance continues where that instance left off.

The following diagram shows an application that is running three (3) application instances.

For More Information

[Apache Kafka Streams](#)

Kafka Streams Configuration

Describes how to configure Kafka Streams.

Kafka Streams Configuration

To configure Kafka Streams, set the following parameters in the Java API StreamsConfig instance:

- (Optional) Set the HPE Ezmeral Data Fabric Streams `streams.default.stream` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

The default stream is used to consume from and send the messages to, if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message will be sent to `/exampleStream:exampleTopic`.

NOTE: If the default stream option is not set and the topic name is specified without a stream name, an exception is thrown.

- Set the Apache Kafka Streams `application.id` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

For more information

- For installation information, see [Installing Kafka Streams](#) on page 205.
- For Apache Kafka Streams information, see [Apache Kafka Streams: Configuring a Streams Application](#).

Supported Apache Kafka Streams APIs

Specifies the supported and not supported Apache Kafka Streams APIs.

Supported APIs

MapR Kafka Streams uses the same APIs as Apache Kafka Streams. Behavior for HPE Ezmeral Data Fabric Streams is the same as for Apache Kafka Streams. See [Apache Kafka Streams documentation](#).

Not Supported APIs

The following `stream` methods in the `StreamsBuilder` class are not supported:

- `<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern)`
- `<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern, Consumed<K,V> consumed)`

Use the following `stream` method instead:

- `<K,V> KStream<K,V>stream(java.util.Collection<java.lang.String> topics)`

Running a Kafka Streams Java App

Describes how to set up and run a Kafka Streams Java application.

Setup

To set up your project, add the required dependencies to the `pom.xml` file, as shown in the example. Note that the versions you use may differ from the versions shown in the example. Version numbers typically change with new releases.

Maven artifacts are published to <https://repository.mapr.com/maven/>. You can also refer to [Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4631 for dependency versions.

Example pom.xml

The following example shows the dependencies you must add to `pom.xml`.

```

<repository>
  <id>mapr-releases</id>
  <url>https://repository.mapr.com/maven/</url>
</repository>
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-clients</artifactId>
  <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-streams</artifactId>
  <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
  <groupId>com.mapr.streams</groupId>
  <artifactId>mapr-streams</artifactId>
  <version>6.2.0.0-mapr</version>
</dependency>
<dependency>
  <groupId>org.rocksdb</groupId>
  <artifactId>rocksdbjni</artifactId>
  <version>5.7.3</version>
</dependency>
<dependency>

```

```
<groupId>commons-logging</groupId>
<artifactId>commons-logging</artifactId>
<version>1.1.1</version>
</dependency>
```

IMPORTANT: For Kafka 2.6.1, enter 5.18.4 as the `rocksdbjni` version, and use `kafka-eventstreams` instead of `mapr-streams`, as shown:

```
<dependency>
  <groupId>org.rocksdb</groupId>
  <artifactId>rocksdbjni</artifactId>
  <version>5.18.4</version>
</dependency>
<dependency>
  <groupId>com.mapr.kafka</groupId>
  <artifactId>kafka-eventstreams</artifactId>
  <version>0.1.0.0-eep-800</version>
</dependency>
```

Running a Kafka Streams App on a Cluster

To run a Kafka Streams Java application on a cluster:

1. Copy the `<Kafka Streams Java application>.jar` file to an arbitrary folder on your cluster.
2. Run the following shell command on your cluster:
 - For Kafka 2.1.1, run:

```
java -cp "$(mapr clientclasspath):<Kafka Streams Java
application>.jar" <Kafka Streams Application Main Class Name>
```

- For Kafka 2.6.1, run:

```
java cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka<version>/libs/
kafka-eventstreams<version>.jar:<Kafka Streams Java application>.jar"
<Kafka Streams Application Main Class Name>
```

Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves records from an `inputTopic` to an `outputTopic`:

```
...
final StreamBuilder builder = new StreamBuilder();
KStream<String,String> source = builder stream(inputTopic);
source.to(outputTopic);
final Topology topology= builder.build();
final KafkaStreams streams=new KafkaStreams(topology, props);
...
streams.start();
...
```

Kafka Streams Demo

Provides a Kafka Streams demo example that creates a stream and topics and runs the `WordCountDemo` class code. The sample code produces and consumes messages.

1. Create the a stream named /sample-stream:

```
maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p
```

2. Create word-count-input and word-count-output topics:

```
maprcli stream topic create -path /sample-stream -topic word-count-input
maprcli stream topic create -path /sample-stream -topic word-count-output
```

3. Build the word count application and copy its JAR file to your cluster.

4. Run the WordCountDemo class.

- For Kafka 2.1.1 and earlier, run:

```
java -cp "$(mapr clientclasspath):<Word Count Application Name>.jar"
WordCountDemo
```

- For Kafka 2.6.1, run:

```
java -cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka-<version>/libs/
kafka-eventstreams<version>.jar:<Word Count Application Name>.jar"
WordCountDemo
```

5. Run the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092
--topic /sample-stream:word-count-input
```

6. Run the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:word-count-output
--property print.key=true
```

7. Produce some input with the console producer:

```
>word27 word28 word27 word29
```

8. Get the following output:

```
word28 1
word27 2
Word29 1
```

WordCountDemo Class Code

```
import org.apache.kafka.common.serialization.Serdes.StringSerde;
import org.apache.kafka.common.serialization.Serdes;
import org.apache.kafka.common.utils.Bytes;
```

```

import org.apache.kafka.streams.KafkaStreams;
import org.apache.kafka.streams.StreamsBuilder;
import org.apache.kafka.streams.StreamsConfig;
import org.apache.kafka.streams.Topology;
import org.apache.kafka.streams.kstream.*;
import org.apache.kafka.streams.state.KeyValueStore;

import java.util.Arrays;
import java.util.Locale;
import java.util.Properties;
import java.util.concurrent.CountDownLatch;

public class WordCountDemo {

    public static final String INPUT_TOPIC = "/
sample-stream:word-count-input";
    public static final String OUTPUT_TOPIC = "word-count-output"; //
Default stream will be used

    public static final String DEFAULT_STREAM = "/sample-stream";

    public static final String APP_ID = "app-id";

    public static void main(String[] args) {
        Properties props = new Properties();
        props.put(StreamsConfig.APPLICATION_ID_CONFIG, APP_ID);
        props.put(StreamsConfig.DEFAULT_KEY_SERDE_CLASS_CONFIG,
StringSerde.class);
        props.put(StreamsConfig.DEFAULT_VALUE_SERDE_CLASS_CONFIG,
StringSerde.class);

        props.put(StreamsConfig.COMMIT_INTERVAL_MS_CONFIG, 500); // Put
attention to this property
        props.put(StreamsConfig.STREAMS_DEFAULT_STREAM_CONFIG,
DEFAULT_STREAM);

        final StreamsBuilder builder = new StreamsBuilder();

        KStream<String, String> wordCountStream = builder.<String,
String>stream(INPUT_TOPIC)
            .flatMapValues(value ->
Arrays.asList(value.toLowerCase(Locale.getDefault()).split("\\W+")))
            .groupBy((key, value) -> value)
            .count(Materialized.<String, Long, KeyValueStore<Bytes,
byte[]>>as("counts-store"))
            .mapValues(x -> x.toString())
            .toStream();

        wordCountStream.to(OUTPUT_TOPIC, Produced.with(Serdes.String(),
Serdes.String()));

        final Topology topology = builder.build();
        final KafkaStreams streams = new KafkaStreams(topology, props);
        final CountDownLatch latch = new CountDownLatch(1);

        // attach shutdown handler to catch control-c
        Runtime.getRuntime().addShutdownHook(new
Thread("streams-shutdown-hook") {
            @Override
            public void run() {
                streams.close();
            }
        });
    }
}

```

```

        latch.countDown();
    }
});

try {
    streams.start();
    latch.await();
} catch (Throwable e) {
    e.printStackTrace();
    System.exit(1);
}
System.exit(0);
}
}

```

 **NOTE:** The `kafka-console-producer.sh` and `kafka-console-consumer.sh` scripts are part of the **mapr-kafka** package.

Application Reset Tool

This tool allows you to reset an application and force it to reprocess its data from scratch by using the application reset tool. This tool can be useful for development and testing, or when fixing bugs.

Description

The application reset tool (ART) handles the Kafka Streams user topics (input, output, and intermediate topics) and internal topics differently when resetting the application.

The application reset tool does the following for each topic type:

- Input topics: Reset to the beginning of the topic. This means that it sets the application's committed consumer offsets for all partitions to each partition's `earliest` offset (for consumer group `application.id`).
- Intermediate topics: Skip to the end of the topic, i.e., set the application's committed consumer offsets for all partitions to each partition's `logSize` (for consumer group `application.id`).
- Internal topics: Delete the internal topic (this automatically deletes any committed offsets).

The application reset tool does not do the following:

- Reset output topics of an application. If any output (or intermediate) topics are consumed by downstream applications, it is your responsibility to adjust those downstream applications as appropriate when you reset the upstream application.
- Reset the local environment of your application instances. It is your responsibility to delete the local state on any machine on which an application instance was run.

See [Confluent Application Reset Tool](#) for additional reference information.

Running the Application Reset Tool

Invoke the application reset tool from the command line:

```
/opt/mapr/bin/kafka-streams-application-reset.sh
```

The tool accepts the following parameters:

 **NOTE:** Parameters can be combined as needed. For example, if you want to restart an application from an empty internal state, but not reprocess previous data, simply omit the `--input-topics` and `--intermediate-topics` parameters.

Option	Description
--application-id <String: id>	(Required) The Kafka Streams application ID (application.id).
--default-stream	The default stream that is used when the topic name is specified but the stream name is not.
--config-file <String: file name>	Property file containing configs to be passed to admin clients and embedded consumer.
--dry-run	Display the actions that would be performed without executing the reset commands.
--input-topics <String: list>	Comma-separated list of user input topics. For these topics, the tool will reset the offset to the earliest available offset.
--intermediate-topics <String: list>	Comma-separated list of intermediate user topics (topics used in the through() method). For these topics, the tool will skip to the end.

Resetting your Local Environments

To reset the local environments of your application instances, you must delete your application's local state directory on any machines where the application instance was run. You must do this before restarting an application instance on the same machine. You can use either of these methods:

 **NOTE:** This is a complete application reset

The API method `KafkaStreams#cleanUp()` in your application code. Manually delete the corresponding local state directory (default location: `/tmp/kafka-streams/<application.id>`). For more information, see `state.dir` `StreamsConfig` class.

Example

In this example you are developing and testing an application locally and you want to iteratively improve your application via run-reset-modify cycles.

```
package mapr.examples.streams;

import ...;

public class ResetDemo {

    public static void main(String[] args) throws Exception {
        // Kafka Streams configuration
        Properties streamsConfiguration = new Properties();
        streamsConfiguration.put(StreamsConfig.APPLICATION_ID_CONFIG,
"my-streams-app");
        // ...and so on...

        // Define the processing topology
        StreamsBuilder builder = new StreamsBuilder();
        builder.stream("my-input-topic")
            .selectKey(...)
            .through("rekeyed-topic")
            .countByKey("global-count")
            .to("my-output-topic");

        KStreams app = new KafkaStreams(builder.build(), streamsConfiguration);

        // Delete the application's local state.
        // Note: In real application you'd call `cleanUp()` only under
```

```

// certain conditions. See tip on `cleanUp()` below.
app.cleanUp();

app.start();

// Note: In real applications you would register a shutdown hook
// that would trigger the call to `app.close()` rather than
// using the sleep-then-close example we show here.
Thread.sleep(30 * 1000L);
app.close();
}
}

```

You can then perform run-reset-modify cycles as follows:

```

# Run your application
$ bin/kafka-run-class mapr.examples.streams.ResetDemo

# After stopping all application instances, reset the application
$ bin/kafka-streams-application-reset.sh --application-id my-streams-app \
                                         --input-topics my-input-topic \
                                         --intermediate-topics rekeyed-topic

# Now you can modify/recompile as needed and then re-run the application
again.
# You can also experiment, for example, with different input data without
# modifying the application.

```

Kafka Streams Security

Discusses Kafka Streams security topics.

Internal Topics

All Kafka Streams application's internal topics are grouped in the Kafka Streams application directory: **/apps/kafka-streams**.

- The **/apps** directory has only write access to **mapr user**. The **/apps/kafka-streams** directory is not modifiable/deletable by any user other than **mapr user**.
- All users can create sub-directories inside the **/apps/kafka-streams** directory. Only the following users have read/write/delete permission for sub-directories or files created in this directory.
 - **mapr user**
 - Current user of the sub-directory:
 - If security is enabled, the current user is the MapR ticket identity. See [Managing Tickets](#) on page 1759 for more information.
 - If security is **not** enabled, the current MapR identity.

Kafka Streams Application Specific Folders

Some Kafka Streams applications need to create internal topics. These topics are created in the **/apps/kafka-streams/<application.id>** directory.

-  **IMPORTANT:** This directory is created at runtime by the Kafka Streams application and can only be modified by the current user or super users. This directory can only be deleted by the [Application Reset Tool](#) on page 4326 (ART) and, again, by only the current user or super users.

Application Reset Tool and Cleanup APIs

The application reset tool allows to reset a Kafka Streams application's internal state, such that it can re-process its input data from scratch. Kafka Streams internal topics can be cleaned using application reset tool.

Only the current user of the Kafka Streams application or **mapr user** has permissions to clean up a Kafka Streams application using Application Reset Tool. The Application Reset Tool is integrated with the cleanup APIs so that the application's internal topics are prefixed with the same directory.

The application reset tool takes `application.id` as the input for cleaning up Kafka Streams application. As part of this process, all internal-topics are deleted for the application user under the **/apps/kafka-streams/<application.id>** directory, including the **/apps/kafka-streams/<application.id>** directory. See [Application Reset Tool](#) on page 4326 for more information.

Changes in Kafka 2.6.1

Describes several differences to note when upgrading from Kafka 2.1.1 to 2.6.1.

Classpath change

- Kafka 2.6.1 uses classes from `kafka-eventstreams.jar` instead of `mapr-streams.jar` to access the cluster.
- If an application fails with a `ClassNotFoundException` or `NoClassDefFoundError` for classes in packages under `com.mapr.kafka.eventstreams.*`, verify that `kafka-eventstreams.jar` is in the Java classpath. You can find `kafka-eventstreams.jar` in the `/opt/mapr/lib/` directory, or you can download it from the Maven repository.

Scala changes

- Scala version 2.11 is no longer supported. Scala versions 2.12 and 2.13 are supported.
- Scala code leveraging the `NewTopic(String, int, short)` constructor with literal values must explicitly call `toShort` on the second literal.

RocksDBs change

- Kafka Streams version 2.6.1 requires RocksDB version 5.18.4.

Default consumer group id

- The default consumer group id has been changed from the empty string (" ") to `null`. Consumers that use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of the consumer configuration. For more information, see [KIP-289](#).

`client.dns.lookup`

The default value for the `client.dns.lookup` configuration has been changed from default to `use_all_dns_ips`. If a hostname resolves to multiple IP addresses, clients and brokers will now attempt to connect to each IP in sequence until the connection is successfully established. For more information, see [KIP-602](#).

DSL

- Use the DSL operator, `cogroup()`, to aggregate multiple streams together at once.
- Kafka Streams DSL switches its used store types. While this change is mainly transparent to users, there are some corner cases that may require code changes.

KStream.toTable() API

Use the `KStream.toTable()` API to translate an input event stream into a `KTable`.

Serde type Void

Use the Serde type, `Void`, to represent null keys or null values from an input topic.

Sticky partitioning

The `DefaultPartitioner` now uses a sticky partitioning strategy. This means that records for a specific topic with null keys and no assigned partition will be sent to the same partition until the batch is ready to be sent. When a new batch is created, a new partition is chosen. This decreases latency to produce, but it may result in uneven distribution of records across partitions in edge cases. Generally, users will not be impacted, but this difference may be noticeable in tests and other situations producing records for a very short amount of time.

Rebalancing

- We are introducing incremental cooperative rebalancing to the clients' group protocol, which allows consumers to keep all of their assigned partitions during a rebalance and in the end revoke only those which must be migrated to another consumer for the overall cluster balance. The `ConsumerCoordinator` will choose the latest `RebalanceProtocol` that is commonly supported by all of the consumer's supported assignors.
- We are introducing a new rebalancing protocol for Kafka Connect based on incremental cooperative rebalancing. The new protocol does not require stopping all the tasks during a rebalancing phase between Connect workers. Instead, only the tasks that need to be exchanged between workers are stopped and they are started in a follow-up rebalance. The new Connect protocol is enabled by default. For more details on how it works and how to enable the old behavior of eager rebalancing, checkout incremental cooperative rebalancing design.

Deprecated APIs

- Deprecated `UsePreviousTimeOnInvalidTimestamp` and replaced with `UsePartitionTimeOnInvalidTimeStamp`.
- Provided support to query stale stores (for high availability) and the stores belonging to a specific partition by deprecating `KafkaStreams.store(String, QueryableStoreType)` and replacing it with `KafkaStreams.store(StoreQueryParameters)`.

- The internal `PartitionAssignor` interface has been deprecated and replaced with a new `ConsumerPartitionAssignor` in the public API. Some methods/signatures are slightly different between the two interfaces. Users implementing a custom `PartitionAssignor` should migrate to the new interface as soon as possible.
- The blocking `KafkaConsumer#committed` methods have been extended to allow a list of partitions as input parameters rather than a single partition. It enables fewer request/response iterations between clients and brokers fetching for the committed offsets for the consumer group. The old overloaded functions are deprecated and we would recommend users making their code changes to leverage the new methods
- The default consumer group id has been changed from the empty string (" ") to `null`. Consumers who use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of their consumer configuration.

Kafka REST Proxy

The Kafka REST Proxy provides a RESTful interface to HPE Ezmeral Data Fabric Streams clusters to consume and produce messages and to perform administrative operations.

It allows you to:

- Consume messages from topics or concrete topic partitions.
- Produce messages to topics or partitions.
- View the state of the cluster.

Use cases include ingesting messages into a stream-processing framework and scripting administrative operations.

Configuration

This section describes how to configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams.

You can set these configuration parameters in the `kafka-rest.properties` file. The Control System displays information about the Kafka REST Proxy for the HPE Ezmeral Data Fabric Streams service. By default, the service runs on port **8082**.

To install the Kafka REST Proxy, see [Installing HPE Ezmeral Data Fabric Streams Tools](#) on page 211.

To configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams, edit the following file:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

To view the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams log files, see the following location:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/logs/kafka-rest.log
```

NOTE: After installation, Warden automatically detects the configuration and starts the service. To configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams, stop the service, configure the parameters, and restart the service. To stop and restart services, see [maprcli node services](#). For example:

```
maprcli node services -name kafka-rest -action stop
```

```
https://<host>:8443/rest/node/services?  
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

Configuration Parameters

This section provides the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams parameters.

These parameters are configurable in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

NOTE: Starting in EEP 8.0.0, Schema Registry (version 6.0.0.0) supports Avro, JSON Schema, and Protobuf formats.

Table

Parameter	Description
<code>api.v2.enable</code>	Enables the REST Proxy v2 API when set to <code>true</code> . Default is <code>true</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>api.v3.enable</code>	Enables the REST Proxy v3 API when set to <code>true</code> . Default is <code>false</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>advertised.listeners</code>	List of advertised listeners used when generating absolute URLs in responses. Supports <code>http</code> and <code>https</code> protocols. Each listener must include the protocol, hostname, and port. For example: <code>http://myhost:8080</code> , <code>https://0.0.0.0:8081</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>schema.registry.enable</code>	Enables Avro serialization and deserialization support with Schema Registry. Starting in Schema Registry 6.0.0.0, enables JSON Schema, and Protobuf serialization and deserialization as well as Avro.
<code>schema.registry.url</code>	The base URL for the schema registry for use by the Avro serializer. Starting in Schema Registry 6.0.0.0, also for use by the JSON Schema and Protobuf serializers, as well as Avro. This setting is ignored if <code>schema.registry.enable</code> is set to <code>false</code> . The default value is resolved from Zookeeper.
<code>schema.registry.service.id</code>	Indicates the ID of the schema registry service. Default: <code>default_</code>
<code>schema.registry.discovery.timeout</code>	The timeout in milliseconds for request to Schema Registry URL storage. Default: 60000
<code>schema.registry.discovery.retries</code>	The number of retries for Schema Registry URL discovery. Default: 6
<code>schema.registry.discovery.interval</code>	The interval in milliseconds between retries for Schema Registry URL discovery. Default: 15000
<code>streams.default.stream</code>	The default stream the consumer should poll messages from and the producer should send messages to. If the topic name does not specify the stream path, and the property has a valid value, then this topic name is found in the default stream.

Table (Continued)

Parameter	Description
id	Unique ID for this REST server instance. This is used in generating unique IDs for consumers that do not specify their ID. The ID is empty by default, which makes a single server setup easier to get up and running, but is not safe for multi-server deployments where automatic consumer IDs are used. Type: string. Default: empty
consumer.threads	The number of threads to run consumer requests on. Type: int. Default: 1
simpleconsumer.cache.max.records	Maximum number of records that can be stored in a single cache. Records with higher offsets replace records with lower ones. The value must be greater than 0. Type: int. Default: 1000.
simpleconsumer.max.caches.num	Maximum number topic-partition combinations for which records are cached. If this parameter is set to 0, then caching is disabled and extra records are thrown away. Cache improves performance if records are fetched sequentially thus increasing offsets. A pool of caches are available to store extra fetch records by a KafkaConsumer for a particular TopicPartition. The cache increases performance when records are fetched from a particular topic partition in a sequential manner. For example, every next request will start with the following offset after the offset of the latest fetched record in the previous request. Type: int. Default: 0
simpleconsumer.max.poll.time	Specifies the maximum number of milliseconds that are spent for polling records by a simpleconsumer. The greater the value means greater latency but higher throughput. Type: int. Default: 1000
simpleconsumer.pool.size.max	Maximum number of SimpleConsumers that can be instantiated. If 0, then the pool size is not limited. Type: int. Default: 25
simpleconsumer.pool.timeout.ms	Amount of time to wait for an available SimpleConsumer from the pool before failing. Use 0 for no timeout. Type: int. Default: 1000
consumer.instance.timeout.ms	Amount of idle time (in milliseconds) before a consumer instance is automatically destroyed. Type: int. Default: 300000 (5 minutes)
consumer.iterator.backoff.ms	Amount of time (in milliseconds) to backoff when an iterator runs out of data. If a consumer has a dedicated worker thread, this is effectively the maximum error for the entire request timeout. This parameter should be small enough to closely target the timeout, but large enough to avoid busy waiting. Type: int. Default: 50
consumer.request.max.bytes	Maximum number of bytes in unencoded message keys and values returned by a single request. This can be used by administrators to limit the memory used by a single consumer and to control the memory usage required to decode responses on clients that cannot perform a streaming decode. Note that the actual payload will be larger due to overhead from base64 encoding the response data and from JSON encoding the entire response. Type: long. Default: 6710884
consumer.request.timeout.ms	The maximum total time (in milliseconds) to wait for messages for a request if the maximum number of messages has not yet been reached. Type: int. Default: 1
producer.threads	Number of threads to run producer requests on. Type: int. Default: 5
producer.streams.buffer.max.time.ms	Buffers messages in the producer for the maximum time specified time. A thread flushes all the messages that have been buffered beyond the time specified. Default: 1

Table (Continued)

Parameter	Description
producers.max.caches.num	Maximum number user names for which producers are cached. If 0, then caching is disabled and producer will be created for each request. Default: 20
request.logger.name	Name of the SLF4J logger to write the NCSA Common Log Format request log. Type: string. Default: io.confluent.rest-utils.requests.
response.mediatype.default	The default response media type that should be used if no specify types are requested in an Accept header. Type: string. Default: application/vnd.kafka.v1+json
response.mediatype.preferred	An ordered list of the server's preferred media types used for responses, from most preferred to least. Type: list. Default: application/vnd.kafka.v1+json, application/vnd.kafka+json, application/json
access.control.allow.methods	Sets the value to the Jetty Access-Control-Allow-Origin header for specified methods. Type: string. Default: empty
access.control.allow.origin	Sets the value for the Jetty Access-Control-Allow-Origin header. Type: string. Default: empty
host.name	The host name used to generate absolute URLs in responses. If empty, the default canonical hostname is used. Type: string. Default: empty
debug	Boolean indicating whether extra debugging information is generated in some error response entities. Type: Boolean. Default: false
shutdown.graceful.ms	Amount of time to wait after a shutdown request for outstanding requests to complete. Type: int. Default: 1000
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporterinterface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics. Type: list. Default: empty
metrics.jmx.prefix	Prefix to apply to metric names for the default JMX reporter. Type: string. Default: kafka.rest
metrics.num.samples	The number of samples maintained to compute metrics. Type: int. Default: 2
metrics.sample.window.ms	The metrics system maintains a configurable number of samples over a fixed window size. This configuration controls the size of the window. For example, used to maintain two samples each measured over a 30 second period. When a window expires, the oldest window is erased and overwritten. Type: long. Default: 30000

Security Parameters

Describes Kafka REST security parameters.

By default, Kafka REST is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka REST.

Starting in EEP 7.0.0 (Core 6.2.0 and KAKFA REST 5.2.1.0) impersonation and authentication are disabled, by default, in insecure clusters.

Configure security for Kafka REST through the security parameters in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

NOTE: Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

Table

Parameter	Description	Type	Default
<code>authentication.cookie.expiration</code>	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
<code>authentication.enable</code>	Whether or not to enable authentication.	boolean	false
<code>impersonation.enable</code>	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user.	boolean	false
<code>listeners</code>	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8082</code>	list	none
<code>ssl.cipher.suites</code>	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
<code>ssl.cipher.suites.exclude</code>	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> • TLS_DHE.* • TLS_EDH.* • .DES. • .MD5. • .RC4.
<code>ssl.client.auth</code>	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.	boolean	false
<code>ssl.disabled.protocols</code>	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> • SSLv3 • TLSv1.0
<code>ssl.enabled.protocols</code>	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
<code>ssl.endpoint.identification.algorithm</code>	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.	string	none

Table (Continued)

Parameter	Description	Type	Default
ssl.key.password	<p>The password of the private key in the keystore file.</p> <p>This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.</p> <p> NOTE: If the <code>ssl-client.xml</code> file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keymanager.algorithm	<p>The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.</p>	string	empty
ssl.keystore.location	<p>Location of the keystore file.</p> <p>This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.</p> <p> NOTE: If the <code>ssl-client.xml</code> file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keystore.password	<p>The store password for the keystore file.</p> <p>This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.</p> <p> NOTE: If the <code>ssl-client.xml</code> file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the <code>SslContextFactory</code> .	string	TLS-v1.2-
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty

Table (Continued)

Parameter	Description	Type	Default
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

SSL Security Configuration

Describes how to configure Kafka REST security.

Secure by Default

As of MapR 6.0, the MapR Installer performs the Kafka REST configuration for new installations. This means that:

- If MapR core is installed as *secure*, then Kafka REST is also installed as *secure*.
- If MapR core is installed as *insecure*, then Kafka REST is also installed as *insecure*.

Manually Securing Kafka REST Only

 **CAUTION:** This configuration is *not* a typical configuration.

If you have an *insecure* MapR cluster, and you want to *secure* Kafka REST, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `kafka-rest.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8082,https://0.0.0.0:8085
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8085/streams/%2Ftesting/topics --cacert
<certificate-path>
```

Manually Unsecuring Kafka REST

 **WARNING:** This scenario is *NOT* recommended or supported.

If you have an *secure* MapR cluster, and you want to *insecure* Kafka REST, do the following:

1. In the `kafka-rest.properties` configuration file, change **https://** to **http://** for the listeners and remove the **ssl.*** properties. For example:

```
listeners=http://0.0.0.0:8082
```

2. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

User Impersonation

Describes how to disable, enable, and use impersonation with Kafka REST.

User impersonation enables Kafka REST jobs to be submitted as a particular user. Without impersonation, Kafka REST submits jobs as the user that started Kafka REST server.

On an HPE Ezmeral Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation is disabled for unsecured clusters and enabled for secure clusters.

Enabling User Impersonation

To enable user impersonation, set the following properties in `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties`:

- `authentication.enable=true`
- `impersonation.enable=true`

Disabling User Impersonation

In the `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties` file, disable PAM authentication and the `impersonation.enable` property.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable user impersonation, set `impersonation.enable=false`.

Example: Verify that a list of topics is owned by an impersonated user

This example demonstrates how to get a list of topics from a particular stream and then verifies that the list of topics is owned by a particular user. Depending on whether or not impersonation is enabled (the default), you may need to use a different `curl` command.

```
$ sudo maprcli stream info -json -path /stream
{
  "timestamp":1598950735841,
  "timeofday":"2020-09-01 08:58:55.841 GMT+0000 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "path":"/stream",
      "physicalsize":57344,
      "logicalsize":32768,
      "numtopics":1,
      "defaultpartitions":1,
      "ttl":604800,
      "compression":"lz4",
```

```

        "autocreate":true,
        "produceperm":"u:root",
        "consumeperm":"u:root",
        "topicperm":"u:root",
        "copyperm":"u:root",
        "adminperm":"u:root",
        "kafkatopic":false,
        "ischangelog":false,
        "defaulttimestamptype":"CreateTime",
        "compact":false,
        "mincompactionlag":0,
        "deleteretention":86400000,
        "throttlefactor":0,
        "pidexpirysecs":604800
    }
]
}

```

If impersonation is enabled (the default), use the following query, where the query is submitted as the root user.

```

curl -u root -X GET https://`hostname`:8082/topics/
%2Fstream%3Atopic1 --cacert /opt/mapr/conf/ssl_truststore.pem
Enter host password for user 'root':
{"name":"/stream:topic1","configs":null,"partitions":
  [{"partition":0,"leader":0,"replicas":
    [{"broker":0,"leader":true,"in_sync":true},
     {"broker":0,"leader":false,"in_sync":true}]}]}

```

If impersonation is disabled, use the following query, where the query is submitted as the mapr user.

```

curl -X GET https://`hostname`:8082/topics/%2Fstream%3Atopic1 --cacert /opt/
mapr/conf/ssl_truststore.pem
{"error_code":40401,"message":"Topic not found."}

```

Saving Kafka REST Configurations

Describes how Kafka REST configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka REST is stored in a folder with a timestamp.

- The configuration files are saved *and* overwritten by new configuration files when upgrading from:
 - 4.1.0 to 5.1.2
 - 5.1.2 to 6.0.0.0
- The configuration files are saved only (not overwritten) when upgrading from:
 - 5.1.2 to 5.1.2

Example

The following example shows the list of configuration files that are saved when upgrading from mapr-kafka-rest 5.1.2 (EEP 7.0.0) to mapr-kafka-rest 5.1.2 (EEP 7.0.1):

```

ls /opt/mapr/kafka-rest/
kafka-rest-5.1.2  kafka-rest-5.1.2.0.202009100923  kafka-restversion

ls /opt/mapr/kafka-rest/kafka-rest-5.1.2.0.202009100923/config/
headers.xml  kafka-rest.properties  log4j.properties  warden.kafka-rest.conf

```

Services Management

The Kafka REST Proxy for HPE Ezmeral Data Fabric Streams service can be started, restarted, and stopped via the `maprcli nodes services` command or using the REST API equivalent.

The following `maprcli nodes services` commands summarize the commands. For more information, see [node services](#) on page 2181.

CLI commands

```
maprcli node services -name kafka-rest -action start -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action restart -nodes <node_list>
```

REST

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

HTTP Methods and URI Summary

This section provides HTTP method and URI summaries for multiple Kafka REST Proxy API versions for HPE Ezmeral Data Fabric Streams.

API v3: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v3 started in Kafka REST 6.0.0.0 on Core 6.2.0.

API v3 is disabled by default. To enable API v3, set the `api.v3.enable` parameter in the `kafka-rest.properties` file to `true`. See [Configuration Parameters](#) on page 4332.

NOTE: Kafka REST 6.0.0.0 supports [API v3](#) and [API v2](#) only. Kafka REST 6.0.0.0 does not support API v1.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	GET /v3/clusters on page 4358	Retrieves a list of metadata about clusters. Only retrieves the current HPE Ezmeral Data Fabric cluster.
GET	GET /v3/clusters/{string: cluster_id} on page 4360	Retrieves metadata about a specific cluster.
GET	GET /v3/clusters/{string: cluster_id}/topics on page 4361	Retrieves a list of topic names on the specific cluster.
POST	POST /v3/clusters/{string: cluster_id}/topics on page 4370	Creates a new topic on the specific cluster.
DELETE	DELETE /v3/clusters/{string: cluster_id}/topics/{string: topic_name} on page 4371	Deletes a topic from the specific cluster.
GET	GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name} on page 4362	Retrieves metadata about a specific topic within a cluster.
GET	GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions on page 4364	Retrieves a list of partitions for the topic within a cluster.

HTTP Method	URI	Description
GET	GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id} on page 4366	Retrieves metadata about a specific partition within a topic and a cluster.
GET	GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas on page 4367	Retrieves a list of replicas within a partition, a topic and a cluster.
GET	GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas/{string: broker_id} on page 4368	Retrieves metadata about a specific replica within a partition, a topic and a cluster.

API v2: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	/topics	Retrieves a list of topic names.
GET	/topics/{string: topic_name}	Retrieves metadata about a specific topic.
POST	/topics/{string: topic_name}	Produces messages to a topic.
GET	/topics/{string: topic_name}/partitions	Retrieves a list of partitions for the topic.
GET	/topics/{string: topic_name}/partitions/{string: partition_id}	Retrieves metadata about a specific partition within a topic.
GET	GET /topics/{string: topic_name}/partitions/{string: partition_id}/offsets on page 4347	Returns a summary with beginning and end offsets for the given topic and specific partition. Supported as of Kafka Rest 6.0.0.0.
POST	/topics/{string: topic_name}/partitions/{string: partition_id}	Produces messages into a partition of a topic.
POST	/consumers/{string: group_name}	Creates a new consumer instance in the consumer group.
DELETE	/consumers/{string: group_name}/instances/{string: instance_id}	Destroys the consumer instance.
POST	/consumers/{string: group_name}/instances/{string: consumer_instance_id}/offsets	Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.
GET	/consumers/{string: group_name}/instances/{string: instance_id}/offsets	Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).
POST	/consumers/{string: group_name}/instances/{string: instance_id}/subscription	Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.
GET	/consumers/{string: group_name}/instances/{string: instance_id}/subscription	Gets the current subscribed list of topics.
DELETE	/consumers/{string: group_name}/instances/{string: instance_id}/subscription	Unsubscribes from topics currently subscribed to.

HTTP Method	URI	Description
POST	/consumers/{string: group_name}/instances/{string: instance_id}/assignments	Manually assigns a list of partitions to a consumer.
GET	/consumers/{string: group_name}/instances/{string: instance_id}/assignments	Retrieves the list of partitions manually assigned to this consumer.
POST	/consumers/{string: group_name}/instances/{string: instance_id}/positions	Overrides the fetch offsets that the consumer will use for the next set of records to fetch.
POST	/consumers/{string: group_name}/instances/{string: instance_id}/positions/beginning	Seek to the first offset for each of the given partitions.
POST	/consumers/{string: group_name}/instances/{string: instance_id}/positions/end	Seek to the last offset for each of the given partitions.
GET	GET /consumers/{string: group_name}/instances/{string: instance_id}/records	Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.
GET	/streams/{string: stream_name}/topics	Retrieves a list of topics in a given stream.

API v1: Kafka REST Proxy Summary

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

NOTE: Kafka REST 6.0.0.0 does not support API v1. Kafka REST 6.0.0.0 supports API v1 and v2 only.

HTTP Method	URI	Description
GET	/topics	Retrieves a list of topic names.
GET	/topics/{topic: string}	Retrieves metadata about a specific topic.
POST	/topics/{topic: string}	Produces a message into a topic.
GET	/topics/{topic: string}/partitions	Retrieves a list of partitions for the topic.
GET	/topics/{topic: string}/partitions/{partition_id: string}	Retrieves metadata about specific partition in a topic.
POST	/topics/{topic: string}/partitions/{partition_id: string}	Produces messages to one partition of the topic.
GET	/topics/{topic: string}/partition/{partition_id: string}/messages?offset={int}&count={int}	Consumes messages from one partition of the topic.
GET	/stream/{stream: string}/topics	Retrieves a list of topics in a given stream.
POST	/consumers/{group: string}	Creates a new consumer instance in the consumer group.
POST	/consumers/{group: string}/instances/{instance: string}/offsets	Commits offsets for the consumer. Returns a list of the partitions with the committed offsets.
DELETE	/consumers/{group: string}/instances/{instance: string}	Destroys the consumer instance.
GET	/consumers/{group: string}/instances/{instance: string}/topics/{topic: string}	Consumes messages from a topic.

API v2 HTTP Methods and URIs

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

GET /topics

Retrieves a list of topic names.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4332

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Returns a list of topic names in the default stream. Returns topic names that contain a stream path.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}

Syntax

```
http://<host>:8082/topics
```

Request Example

```
$ curl "Content-Type: application/vnd.kafka.v2+json" "http://localhost:8082/topics"
```

Response Example

```
[
  "streaming_data/stream:testtopic1",
  "streaming_data/stream:testtopic2"
]
```

GET /topics/{string: topic_name}

Retrieves metadata about a specific topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4332

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, topic1 is equivalent to default_stream:topic1
<code>streams.default.stream</code> is not defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic. A fully qualified topic name is passed that contains the stream path.

NOTE: The full name for the HPE Ezmeral Data Fabric Streams topic contains characters such as a forward slash (/) and a colon (:), therefore, it should be encoded. For example, /streaming_data/stream:topic-1 is equivalent to %2Fstreaming_data%2Fstream%3Atopic-1.

Table

Parameters	Description
topic_name (string)	Name of the topic to get metadata about.

Syntax

Syntax for a topic in a default stream where the default stream is configured:

```
http://<host>:8082/topics/<topic_string>
```

Syntax for a topic where the fully qualified topic name is specified:

```
http://<host>:8082/topics/%2F<streaming_data>%2F<stream>%3A<topic1>
```

Request Example

```
curl "http://localhost:8082/topics/test"
```

Response Example

```
{
  "name": "test",
  "configs": null,
  "partitions":
  [
    {
      "partition": 0,
      "leader": 0,
      "replicas":
      [
        {"broker": 0, "leader": true, "in_sync": true},
        {"broker": 0, "leader": false, "in_sync": true}
      ]
    }
  ]
}
```

POST /topics/{string: topic_name}
Produces messages to a topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4332

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Produces messages into specific HPE Ezmeral Data Fabric Streams topics. If the topic name does not contain a stream path, then the default stream path is used.

Table (Continued)

Parameters Defined	Response
streams.default.stream is not defined	Produces messages into a HPE Ezmeral Data Fabric Streams topic. The topic name should contain a stream path and be encoded.

NOTE: If the topic does not exist, the following error results: [{"error_code":40401, "message": "Topic not found."}]. New topics are not created by the POST operation.

Table

Parameters	Description
topic_name (<i>string</i>)	Name of the topic to produce the messages to.

Syntax

```
http://<host>:8082/topics/<topic_string>
```

Request Example

This example produces a message using binary embedded data with the value, Kafka, to the topic, test.

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2" --data
'{"records":[{"value":"S2Fma2E="}]}' "http://localhost:8082/topics/test"
```

Response Example

```
{
  "offsets":
  [
    {
      "partition":0,
      "offset": 1,
      "error_code":null,
      "error":null
    }
  ],
  "key_schema_id":null,
  "value_schema_id":null
}
```

GET /topics/{string: topic_name}/partitions
Retrieves a list of partitions for the topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within a topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
topic_name (<i>string</i>)	Name of the topic.

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
"http://localhost:8082/topics/testtopic1/partitions"
```

Response Example

```
[
  {
    "partition":0,
    "leader":0,
    "replicas":
      [
        {
          "broker":0,
          "leader":true,
          "in_sync":true
        }
      ]
  },
  {
    "partition":1,
    "leader":0,
    "replicas":
      [
        {
          "broker":0,
          "leader":true,
          "in_sync":true
        }
      ]
  }
]
```

GET /topics/{string: topic_name}/partitions/{string: partition_id}
Retrieves metadata about a specific partition within a topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about a specific partition within a HPE Ezmeral Data Fabric Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

Table

Parameters	Description
topic_name (<i>string</i>)	Name of the topic.
partition_id (<i>int</i>)	ID of the partition to inspect.

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/
partitions/0
```

Response Example

```
{
  "partition":0,
  "leader":0,
  "replicas":
  [
    {
      "broker":0,
      "leader":true,
      "in_sync":true
    }
  ]
}
```

GET /topics/{string: topic_name}/partitions/{string: partition_id}/offsets

Returns a summary with beginning and end offsets for the given topic and specific partition.

Description

Information retrieved varies depending on the configuration. See the `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets summary with beginning and end offsets for the specific partition of the HPE Ezmeral Data Fabric Streams topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets summary with beginning and end offsets for the specific HPE Ezmeral Data Fabric Streams partition within a topic. You can only pass the fully qualified topic names that contain the stream path.

Table

Parameter	Description
topic_name (<i>string</i>)	Name of the topic.
partition_id (<i>int</i>)	ID of the partition to inspect.

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>/offsets
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2" http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/partitions/0/offsets
```

Response Example

```
{
  "beginning_offset":0,
  "end_offset":0
}
```

POST /topics/{string: topic_name}/partitions/{string: partition_id}
Produces messages into a partition of a topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Produces messages into a partition of HPE Ezmeral Data Fabric Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, messages are produced into topics in the default stream path.
<code>streams.default.stream</code> is not defined	Produces messages into a partition within HPE Ezmeral Data Fabric Streams topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<code>topic_name</code> (<i>string</i>)	Topic to produce the messages to.
<code>partition_id</code> (<i>int</i>)	Partition to produce the messages to.

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2+json" --data '{"records":[{"key":"a2v5","value":"Y29uZmx1ZW50"}]}' "http://localhost:8082/topics/testtopic1/partitions/0"
```

Response Example

```
{
  "offsets":
  [
    {
      "partition": 0,
      "offset": 1,
      "error_code": null, "error": null}
  ],
  "key_schema_id": null,
  "value_schema_id": null
}
```

POST /consumers/{string: group_name}
Creates a new consumer instance in the consumer group.

Description

Table

Parameters	Description
group_name (<i>string</i>)	The name of the consumer group to join.
name (<i>string</i>)	Name for the consumer instance, which will be used in URLs for the consumer. This must be unique, at least within the proxy process handling the request. If omitted, falls back on the automatically generated ID. Using automatically generated names is recommended for most use cases.
format (<i>string</i>)	The format of consumed messages, which is used to convert messages into a JSON-compatible form. Valid values: "binary", "avro", "json". If unspecified, defaults to "binary".
auto.offset.reset (<i>string</i>)	Sets the auto.offset.reset setting for the consumer. Values: latest, earliest, none
auto.commit.enable (<i>string</i>)	Sets the auto.commit.enable setting for the consumer.

NOTE: You cannot set the time-to-live (TTL) for consumer instances or consumer groups. However, consumers can be configured to be deleted after some idle time. The amount of idle time before a consumer instance is automatically destroyed is set by the `consumer.instance.timeout.ms` property in the **kafka-rest.properties** file. See [Configuration Parameters](#) on page 4332.

Syntax

```
http://<host>:8082/consumers/<group_name>
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json"
--data '{"name": "user", "format": "binary", "auto.offset.reset":
"earliest"}'
http://localhost:8082/consumers/groupstest
```

Response Example

The response JSON object is in the following form:

- **instance_id** (*string*) – Unique ID for the consumer instance in this group. The `instance_id` is automatically generated if the `name` parameter is not specified.

- **base_uri** (*string*) – Base URI used to construct URIs for subsequent requests against this consumer instance. This will be of the form `http://hostname:port/consumers/consumer_group/instances/instance_id`.

```
{
  "instance_id": "user",
  "base_uri": "http://localhost:8082/consumers/groupptest/instances/
user"
}
```

DELETE /consumers/{string: group_name}/instances/{string: instance_id}
Destroys the consumer instance.

Description

The request must be made to the specific REST proxy instance holding the consumer instance.

Table

Parameters	Description
group_name (<i>string</i>)	The name of the consumer group.
instance (<i>string</i>)	The ID of the consumer instance

Syntax

```
http://<host>:8082/topics/<group_name>/instances/<instance_string>
```

Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/consumers/my_binary_consumer/instances/
rest-consumer-11561681-
8ba5-4b46-bed0-905ae1769bc6
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: consumer_instance_id}/offsets
Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.

Parameters

Table

Parameters	Description
group_name (<i>string</i>)	The name of the consumer group.
instance_id (<i>string</i>)	The ID of the consumer instance.
offsets	A list of offsets to commit for partitions.
offsets[i].topic (<i>string</i>)	Name of the topic
offsets[i].partition (<i>int</i>)	Partition ID
offset	The offset to commit.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_instance_id>/offsets
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic":
"/mystream:first", "partition": 0, "offset": 5}]}'
https://node2:8082/consumers/groupptest/instances/user/offsets
```

Response Example

```
HTTP/1.1 200 OK
```

GET /consumers/{string: group_name}/instances/{string: instance_id}/offsets

Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).

Parameters

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.
partitions	A list of partitions to find the last committed offsets.
partitions[i].topic (<i>string</i>)	Name of the topic.
partitions[i].partition (<i>int</i>)	Partition ID

Syntax

```
http://localhost:8082/consumers/<group_name>/instances/<consumer_name>/offsets
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.binary.v2+json" --data
'{"partitions": [{"topic": "/stream:topic", "partition": 0}]}'
https://node2:8082/consumers/groupptest/instances/user/offsets
```

Response Example

The response JSON object is in the following form:

- offsets - A list of committed offsets.
- offsets[i].topic (string) – Name of the topic for which an offset was committed
- offsets[i].partition (int) – Partition ID for which an offset was committed
- offsets[i].offset (int) – Committed offset

- `offsets[i].metadata` (string) – Metadata for the committed offset

```
{ "offsets":
  [
    {
      "topic": "/stream:topic",
      "partition": 0,
      "offset": 21,
      "metadata": ""
    }
  ]
}
```

POST `/consumers/{string: group_name}/instances/{string: instance_id}/subscription`

Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.

Parameters

Table

Parameter	Description
<code>group_name</code> (string)	Name of the consumer group.
<code>instance</code> (string)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"topics":["/stream:first","/stream:second"]}'
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

Response Example

```
HTTP/1.1 204 No Content
```

GET `/consumers/{string: group_name}/instances/{string: instance_id}/subscription`

Gets the current subscribed list of topics.

Parameters

Table

Parameter	Description
<code>group_name</code> (string)	Name of the consumer group.
<code>instance</code> (string)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

Response Example

The response JSON object is in the following form:

- topics – A list of subscribed topics
- topics[i] (string) – Name of the topic

```
{
  "topics": [
    "/stream:first",
    "/stream:second"
  ]
}
```

DELETE /consumers/{string: group_name}/instances/{string: instance_id}/subscription
Unsubscribes from topics currently subscribed to.

Parameters

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/assignments
Manually assigns a list of partitions to a consumer.

Parameters

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions":[{"topic":"first","partition":0}]}'
https://localhost:8082/consumers/groupptest/instances/user/assignments
```

Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group_name}/instances/{string: instance_id}/assignments

Retrieves the list of partitions currently assigned to this consumer.

Parameters

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/assignments
```

Response Example

The response JSON object is in the following form:

- partitions – A list of partitions assigned to this consumer.
- partitions[i].topic (*string*) – Name of the topic.

- `partitions[i].partition (int)` – Partition ID

```
{
  "partitions": [
    {
      "topic": "test",
      "partition": 0
    },
    {
      "topic": "test",
      "partition": 1
    }
  ]
}
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/positions

Overrides the fetch offsets that the consumer will use for the next set of records to fetch.

Parameters

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.
offsets	A list of offsets
offsets[i].topic (<i>string</i>)	Name of the topic
offsets[i].partition (<i>int</i>)	Partition ID
offsets[i].offset (<i>int</i>)	Seek to offset for the next set of records to fetch.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic": "/stream:first", "partition": 0, "offset": 3}]}'
https://localhost:8082/consumers/groupptest/instances/user/positions
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/positions/beginning

Seek to the first offset for each of the given partitions.

Parameters

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.
partitions	A list of partitions.
partitions[i].topic (<i>string</i>)	Name of the topic
partitions[i].partition (<i>int</i>)	Partition ID

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/beginning
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
https://localhost:8082/consumers/groupptest/instances/user/positions/
beginning
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/positions/end
Seek to the last offset for each of the given partitions.

Parameters

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.
partitions	A list of partitions.
partitions[i].topic (<i>string</i>)	Name of the topic
partitions[i].partition (<i>int</i>)	Partition ID

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/end
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
https://localhost:8082/consumers/groupptest/instances/user/positions/end
```

Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group_name}/instances/{string: instance_id}/records

Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.

Parameters

The format of the embedded data returned by this request is determined by the format specified in the initial consumer instance creation request and must match the format of the Accept header.

NOTE: This request *must* be made to the specific REST proxy instance holding the consumer instance.

Table

Parameter	Description
group_name (<i>string</i>)	Name of the consumer group.
instance (<i>string</i>)	ID of the consumer instance.
timeout	The number of milliseconds for the underlying client library poll(timeout) request to fetch the records. Default: 5000ms.
max_bytes	The maximum number of bytes of unencoded keys and values that should be included in the response. This provides approximate control over the size of responses and the amount of memory required to store the decoded response. The actual limit is the minimum of this setting and the server-side configuration consumer.request.max.bytes. Default: unlimited

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/records
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/records
```

Response Example

```
[
  {
    "topic": "test",
    "key": "a2V5",
    "value": "Y29uZmx1ZW50",
    "partition": 1,
    "offset": 100,
  },
  {
```

```

    "topic": "test",
    "key": "a2V5",
    "value": "a2Fma2E=",
    "partition": 2,
    "offset": 101,
  }
]

```

GET /streams/{string: stream_name}/topics
Retrieves a list of topics in a given stream.

Description

Stream names contain characters such as backslashes (/) and colons (:), and, therefore, should be encoded.

Table

Parameters	Description
stream_name (<i>string</i>)	The name of the stream.

Syntax

```
http://<host>:8082/streams/<stream_name>/topics
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/streams/%2Fstreaming_data%2Fstream/topics
```

Response Example

```

[
  "/streaming_data/stream:testtopic1",
  "/streaming_data/stream:testtopic2"
]

```

API v3 HTTP Methods and URIs

Availability of Kafka REST Proxy API v3 started in Kafka REST 6.0.0.0 on Core 6.2.0. API v3 is disabled by default. To enable API v3, set the `api.v3.enable` parameter in the `kafka-rest.properties` file to `true`. See [Configuration Parameters](#).

NOTE: Kafka REST 6.0.0.0 supports [API v3](#) and [API v2](#) only. Kafka REST 6.0.0.0 does not support API v1.

GET /v3/clusters
Retrieves a list of metadata about the cluster.

Description

Retrieves one cluster only. Always retrieves the current HPE Ezmeral Data Fabric cluster.

Syntax

```
http://<host>:8082/v3/clusters
```

Request Example

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/clusters
```

Response Example

```
{
  "kind": "KafkaClusterList",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters",
      "next": null
    },
  },
  "data": [
    {
      "kind": "KafkaCluster",
      "metadata": {
        {
          "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619",
          "resource_name": "crn:///kafka=682798077049224619"
        },
        "cluster_id": "682798077049224619",
        "controller": {

GET /v3/clusters/{string: cluster_id}
Retrieves metadata about a specific cluster.

Parameters

Parameters	Description
cluster_id (string)	Cluster's id.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>
```

Request Example

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/clusters/682798077049224619
```

Response Example

```
{
  "kind": "KafkaCluster",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619",

```

GET /v3/clusters/{string: cluster_id}/topics

Retrieves a list of topic names on the specific cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Returns a list of topic names and metadata in the default stream. Returns topic names and metadata that contains a stream path.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
<code>cluster_id</code> (<i>string</i>)	Cluster's id.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics"
```

Response Example

```

        }
    }
    ]
}

```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}
Retrieves metadata about a specific topic within a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic on this cluster. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, <code>topic1</code> is equivalent to <code>default_stream:topic1</code> .
<code>streams.default.stream</code> is not defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic on this cluster. A fully qualified topic name is passed that contains the stream path.

NOTE: The full name for the HPE Ezmeral Data Fabric Streams topic contains characters such as a forward slash (/) and a colon (:). Therefore, the topic should be encoded. For example, `/streaming_data/stream:topic-1` is equivalent to `%2Fstreaming_data%2Fstream%3Atopic-1`.

Table

Parameters	Description
<code>cluster_id</code> (<i>string</i>)	Cluster's id.
<code>topic_name</code> (<i>string</i>)	Name of the topic.

Syntax

```
http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2"
```

Response Example

```

    }
  }
}

```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions
Retrieves a list of partitions for the topic within a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within a topic on this cluster. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within topic on this cluster. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<code>cluster_id</code> (<i>string</i>)	Cluster's id.
<code>topic_name</code> (<i>string</i>)	Name of the topic.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics/tp-2/partitions"

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}
Retrieves metadata about a specific partition within a topic and a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about a specific partition within a HPE Ezmeral Data Fabric Streams topic on this cluster. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

Table

Parameters	Description
<code>cluster_id</code> (<i>string</i>)	Cluster's id.
<code>topic_name</code> (<i>string</i>)	Name of the topic.
<code>partition_id</code> (<i>int</i>)	ID of the partition to inspect.

Syntax

```

http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>

```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics/tp-2/partitions/1"
```

Response Example

```
{
  "kind": "KafkaPartition",
  "metadata": {
    "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1",
    "resource_name": "crn:///kafka=682798077049224619/topic=str:tp-2/partition=1"
  },

  "leader": {
    "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1/replicas/0"
  },
  "replicas": {
    "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1/replicas"
  },
  "reassignment": {
    "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1/reassignment"
  }
}
```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas
Retrieves a list of replicas within a partition, a topic, and a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about specific replicas of the HPE Ezmeral Data Fabric Streams partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific replicas of the HPE Ezmeral Data Fabric Streams partition within a topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
cluster_id (<i>string</i>)	Cluster's id.
topic_name (<i>string</i>)	Name of the topic.
partition_id (<i>int</i>)	ID of the partition to inspect.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas"
```

Response Example

      ]
    }
  }
}
```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas/{string: broker_id}

Retrieves metadata about a specific replica within a partition, a topic, and a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about specific broker of the HPE Ezmeral Data Fabric Streams partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific broker of the HPE Ezmeral Data Fabric Streams partition within a topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<code>cluster_id</code> (<i>string</i>)	Cluster's id.
<code>topic_name</code> (<i>string</i>)	Name of the topic.
<code>partition_id</code> (<i>int</i>)	ID of the partition to inspect.
<code>broker_id</code> (<i>int</i>)	ID of the broker to inspect.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas/<broker_id>
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas/0"
```

Response Example

```
{
  "kind": "KafkaReplica",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/
topics/str:tp-2/partitions/1/replicas/0",
      "resource_name": "crn:///kafka=682798077049224619/topic=str:tp-2/
partition=1/replica=0"
    },
    "cluster_id": "682798077049224619",
    "topic_name": "/str:tp-2",
    "partition_id": 1,
    "broker_id": 0,
    "is_leader": true,
    "is_in_sync": true,
    "broker": {
      "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/brokers/0"
    }
  }
}
```

```
}
}
```

POST /v3/clusters/{string: cluster_id}/topics
Creates a new topic on the specific cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Creates a topic in the default stream and returns its metadata.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
<code>cluster_id</code> (<i>string</i>)	Cluster's id.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

Request Example

```
$ curl -X POST -H "Content-Type: application/json" --data '{"topic_name": "new-topic", "partitions_count": 4}' "http://localhost:8082/v3/clusters/682798077049224619/topics"
```

Request Response

```
{
  "kind": "KafkaTopic",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/new-topic",
      "resource_name": "crn:///kafka=682798077049224619/topic=new-topic"
    }
  },
  "cluster_id": "682798077049224619",
  "topic_name": "new-topic",
  "is_internal": false,
  "replication_factor": 0,
  "partitions": {
    {
      "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/new-topic/partitions"
    }
  },
  "configs": {
    {
      "related": "http://node1.cluster.com:8082/v3/clusters/"
    }
  }
}
```

```

682798077049224619/topics/new-topic/configs"
  },
  "partition_reassignments": {
    "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/partitions/-/reassignment"
  }
}

```

DELETE /v3/clusters/{string: cluster_id}/topics/{string: topic_name}

Deletes a topic from the specific cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4332.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Deletes topic from the default stream.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
<code>cluster_id</code> (<i>string</i>)	Cluster's id.
<code>topic_name</code> (<i>string</i>)	Name of the topic.

Syntax

```

http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>

```

Request Example

```

$ curl -X DELETE -H "Content-Type: application/json" "http://
localhost:8082/v3/clusters/682798077049224619/topics/new-topic"

```

Response Example

```

HTTP/1.1 204 No Content

```

Kafka Connect

Kafka Connect is a utility for streaming data between HPE Ezmeral Data Fabric Streams and other storage systems.

Examples of other systems include:

- Relational databases
- Logs and metrics
- Hadoop and data warehouses

- NoSQL data stores

Kafka Connect makes it easy to integrate all your data via Kafka, making it available as realtime streams. For example, you can use Kafka Connect to:

- Stream changes from a relational database to make events available with low latency for stream processing applications.
- Import realtime logs and metrics into HPE Ezmeral Data Fabric Streams and process them to detect anomalies.
- Implement a process of loading data into HPE Ezmeral Data Fabric Streams from your primary data storage systems, performing filtering, transformations, and enrichment with a stream processing framework, and publish the data to the HPE Ezmeral Data Fabric File Store.

NOTE: Built-in security is not available.

Architecture of Kafka Connect

Kafka Connect for HPE Ezmeral Data Fabric Streams has the following major models in its design: connector, worker, and data.

Connector Model

A connector is defined by specifying a Connector class and configuration options to control what data is copied and how to format it.

- Each Connector instance is responsible for defining and updating a set of Tasks that actually copy the data.
- Kafka Connect manages the Tasks; the Connector is only responsible for generating the set of Tasks and indicating to the framework when they need to be updated.
- Source and Sink Connectors/Tasks are distinguished in the API to ensure the simplest possible API for both.

There are two types of tasks:

- **Source** - Source tasks ingest data from data storage systems and stream the data to HPE Ezmeral Data Fabric Streams.
- **Sink** - Sink tasks stream data from HPE Ezmeral Data Fabric Streams to other storage systems.

HPE Ezmeral Data Fabric supports the following connectors:

- JDBC Source Connector

The Kafka JDBC source connector is a type connector used to stream data from relational databases into HPE Ezmeral Data Fabric Streams topics. JDBC Source Connector for HPE Ezmeral Data Fabric Streams supports integration with Hive 2.1.

- JDBC Sink Connector

The Kafka JDBC sink connector is a type connector used to stream data from HPE Ezmeral Data Fabric Streams topics to relational databases that have a JDBC driver.

- HDFS Sink Connector

The Kafka HDFS sink connector is a type connector used to stream data from HPE Ezmeral Data Fabric Streams to file system. By default, the resulting data is produced to file system in Avro format. In addition, Parquet files can be written to file system.

Worker Model

A Kafka Connect for HPE Ezmeral Data Fabric Streams cluster consists of a set of Worker processes that are containers that execute Connectors and Tasks. A worker is a JVM process with a REST API that is able to execute streaming tasks.

- Workers automatically coordinate with each other to distribute work and provide scalability and fault tolerance.
- The Workers distribute work among any available processes, but are not responsible for management of the processes;
- Any process management strategy can be used for Workers. For example, cluster management tools like YARN or Mesos, configuration management tools like Chef or Puppet, or direct management of process lifecycles.

Data Model

Connectors copy streams of messages from a partitioned input stream to a partitioned output stream, where at least one of the input or output is *always* Kafka.

- Each of these streams is an ordered set messages where each message has an associated offset.
- The format and semantics of these offsets are defined by the Connector to support integration with a wide variety of systems; however, to achieve certain delivery semantics in the face of faults requires that offsets are unique within a stream and streams can seek to arbitrary offsets.
- Message contents are represented by Connectors in a serialization-agnostic format.
- Pluggable Converters are available for storing this data in a variety of serialization formats.
- Schemas are built-in, allowing important metadata about the format of messages to be propagated through complex data pipelines. However, schema-free data can also be use when a schema is simply unavailable.

Connectors, Tasks, and Workers

Describes how Kafka Connect for HPE Ezmeral Data Fabric Streams works and how connectors, tasks, offsets, and workers are associated.

Connectors

Connectors (or a **connector instance**) are logical jobs that are responsible for managing the copying of data between HPE Ezmeral Data Fabric Streams and another systems. Each connector instantiates a set of **tasks** that copies the data. By allowing the connector to break a single job into many tasks, support is built-in for parallelism and scalable data copying with very little configuration. **Connector plugins** are jars that add the classes that implement a connector.

Offsets

As connectors run, Kafka Connect tracks **offsets** for each one so that connectors can resume from their previous position in the event of failures or graceful restarts for maintenance. They track the current position in the stream of data being copied and because each connector may need to track many offsets for different **partitions** of the stream. For example, when loading data from a database, the offset might be a transaction ID that identifies a position in the database change log.

Users generally do not need to worry about the format of offsets, especially since they differ from connector to connector. However, Kafka Connect does require persistent storage for offset data to ensure it can recover from faults. This storage for offset data is configurable. See [Standalone Worker Configuration Options](#) on page 4378 and [Distributed Worker Configuration Options](#) on page 4379.

Workers

Connectors and tasks are logical units of work and must be scheduled to execute in a process. Kafka Connect calls these processes **workers**. With Kafka Connect for MapR streams, the worker processors run as a service. This service can be run in either standalone mode or distributed mode.

- In standalone mode, the cluster consists of a single worker that is supplied with tasks that are useful for testing and debugging purposes.
- In distributed mode, the cluster consisting from multiple workers with the same `group.id`, `offset.storage.topic`, and `config.storage.topic`. Connector tasks are submitted via the Kafka Connect REST API.

The following list the location of the standalone and distributed worker configuration files:

```
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

NOTE: Distributed mode is supported on MapR 5.2.1 and above

NOTE: Port 8083 is the default port.

NOTE: If you running multiple workers on the same node, the `rest.port` parameter must be different for each worker.

Configuring in Standalone Mode

The section describes how to configure and execute workers in Kafka connect standalone mode.

Standalone mode is the simplest mode, where a single process is responsible for executing all connectors and tasks. Since it is a single process, it requires minimal configuration.

Configuring and running in standalone mode, involves configuring the standalone properties and connector parameters before executing the standalone shell command along with the properties files on the command line.

The following parameters must be provided in the **connect-standalone.properties** file.

- `offset.storage.file.filename` - Storage for connector offsets which are stored on the local filesystem in standalone mode. Using the same file leads to offset data being deleted or overwritten with different values.
- `rest.port` - Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this parameter must have different values for each instance.

NOTE: If you are running multiple standalone instances on the same host, these parameters must be different for each instances. Therefore, an additional properties file is created for the instance with different parameter values.

To run a worker in standalone mode:

1. Edit the **./config/connect-standalone.properties** file and add the name of the local file that will store the connector offsets.
2. Edit the **quickstart-sqlite.properties** file (JDBC connector configuration file).
3. Run the **./bin/connect-standalone.sh** command along with the properties files on the command line.

For example:

```
cd /opt/mapr/kafka/kafka-<version>
./bin/connect-standalone.sh
./config/connect-standalone.properties
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-qlite.properties
```

The first parameter is always a configuration file for the worker. This configuration gives you control over settings such as which cluster to use and the serialization format. See [JDBC Connector](#) on page 4383 for more information. All additional parameters should be connector configuration files. Each file contains a single connector configuration.

Configuring in Distributed Mode

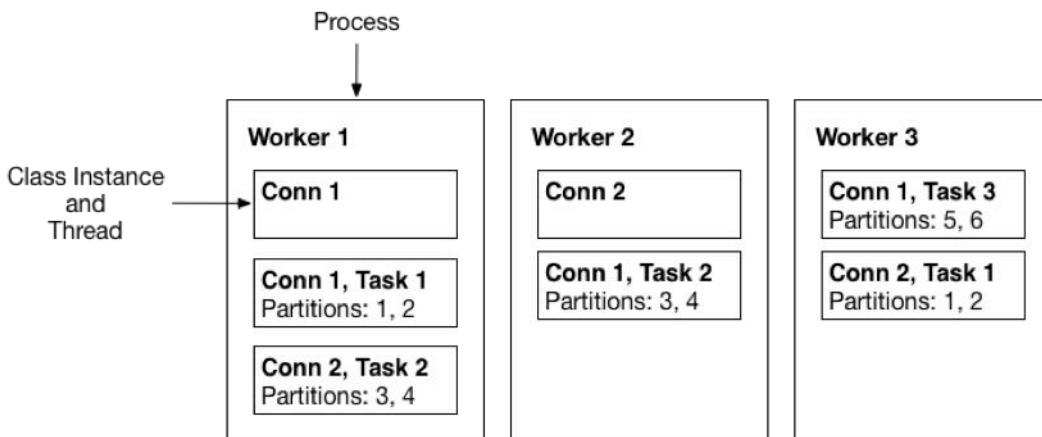

This section describes how to configure and run workers in Kafka Connect distributed mode.

Distributed mode provides scalability and automatic fault tolerance for Kafka Connect. In distributed mode, multiple worker processes are started using the same group.id. These processes automatically coordinate to schedule execution of connectors and tasks across all available workers. If a worker is added, shuts down, or fails unexpectedly, the rest of the workers detect this and automatically coordinate to redistribute connectors and tasks across the updated set of available workers.

NOTE: Distributed mode is available as of EEP 2.0.1.

The following diagrams illustrates a three-node Kafka Connect distributed mode cluster where:

- Connectors are monitoring the source or sink system for changes that require reconfiguring tasks.
- Tasks are automatically balanced across the active workers by copying a subset of a connector’s data.
- The division of work between tasks is shown by the partitions that each task is assigned.

Interaction with a distributed-mode cluster is via the REST API (rather than on the command line). To create a connector, the workers are started and then REST request is made to create a connector. See [REST API](#) on page 4399.

NOTE: Kafka Connect workers do not have a special “leader” process that you have to interact with to use the REST API. All nodes can respond to REST requests, including creating, listing, modifying, and destroying connectors.

To run the worker in distributed mode:

1. In the `connect-distributed.properties` file, define the topics that will store the connector state, task configuration state, and connector offset state.

In distributed mode, the workers need to be able to discover each other and have shared storage for connector configuration and offset data. In addition to the usual worker settings, ensure you have configured the following for the cluster:

- **group.id** - ID that uniquely identifies the cluster these workers belong to. Ensure this is unique for all groups that work with a cluster.
- **config.storage.topic** - Topic to store the connector and task configuration state in. Although this topic can be auto-created if your cluster has auto topic creation enabled, it is highly recommended that you create it before starting the cluster. This topic should **always** have a single partition and be highly replicated (3x or more).
- **offset.storage.topic** - Topic to store the connector offset state in. To support large HPE Ezmeral Data Fabric Streams clusters, this topic should have a large number of partitions (for example, 25 or 50 partitions and highly replicated (3x or more).
- **rest.port** - Port where the REST interface listens for HTTP requests. If you run more than one worker per host (for example, if you are testing distributed mode locally during development), this setting must have different values for each instance.

2. Set the group.id value for all of the workers in the cluster.

NOTE: All workers that belong to the same cluster must have the same group.id value.

3. Start the Kafka Connect service in distributed mode:

```
maprcli node services -name kafka-connect -action start -nodes
<node_list>
```

For more information, see [Managing Kafka Connect Services](#) on page 4393.

NOTE: >Distributed mode does not have any additional command line parameters. If other instances are already running, new workers either start a new group or join an existing one, and then wait for work to do. For information on managing the connectors running in the cluster, see [REST API](#) on page 4399.

Connector Configuration

This section describes how and where connectors are configured.

Connector configurations are key-value mappings. For standalone mode, these parameters are defined in a properties file and passed to the Connect process on the command line. In distributed mode, they will be included in the JSON payload for the request that creates (or modifies) the connector. Most configurations are connector dependent, but there are a few settings common to all connectors:

- name - Unique name for the connector. Attempting to register again with the same name will fail.
- connector.class - The Java class for the connector
- tasks.max - The maximum number of tasks that should be created for this connector. The connector may create fewer tasks if it cannot achieve this level of parallelism.

Sink connectors also have one additional option to control their input:

- topics - A list of topics to use as input for this connector

For other options, consult the documentation for the JDBC and HDFS connectors. See [JDBC Connector](#) on page 4383 and [HDFS Connector](#) on page 4393.

Worker Configuration

This section describes how and where to configure workers.

Whether you're running standalone or distributed mode, Kafka Connect workers are configured by passing a properties file containing any required or overridden options as the first parameter to the worker process.

Common Worker Configuration Options

You can set common worker configuration options for standalone or distributed mode in the `connect-<standalone/distributed>.properties` file. The options control basic functionality, including which cluster to communicate with and data format.

Setting the Schema Registry URL for the Avro Converter

Set the Schema Registry URL for the converter through the following properties:

- `key.converter.schema.registry.url=<URL:PORT>`
- `value.converter.schema.registry.url=<URL:PORT>`
- For Avro, use `io.confluent.connect.avro.AvroConverter`.
- For Protobuf, use `io.confluent.connect.protobuf.ProtobufConverter`.
- For JSON Schema, use `io.confluent.connect.json.JsonSchemaConverter`.

If you do not set these properties, the Schema Registry URL is taken from ZooKeeper.

The following table describes the common worker configuration parameters:

Parameter	Description
plugin.path	The comma-separated list of paths to directories that contain Kafka Connect plugins. <ul style="list-style-type: none"> • Type: string • Default: empty
key.converter	Converter class for key Connect data. This controls the format of the data that will be written to HPE Ezmeral Data Fabric Streams for source connectors or read from MapR Streams for sink connectors. <ul style="list-style-type: none"> • Type: class • Default: empty
value.converter	Converter class for value Connect data. This controls the format of the data that will be written to HPE Ezmeral Data Fabric Streams for source connectors or read from MapR Streams for sink connectors. <ul style="list-style-type: none"> • Type: class • Default: empty
internal.key.converter	Converter class for internal key Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> • Type: class • Default:
internal.value.converter	Converter class for offset value Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> • Type: class • Default:

Parameter	Description
offset.flush.interval.ms	Interval (milliseconds) at which to try committing offsets for tasks. <ul style="list-style-type: none"> Type: long Default: 60000
offset.flush.timeout.ms	Maximum number of milliseconds to wait for records to flush and partition offset data to be committed to offset storage before cancelling the process and restoring the offset data to be committed in a future attempt. <ul style="list-style-type: none"> Type: long Default: 5000
rest.advertised.host.name	If set, this is the hostname that will be given out to other workers to connect to. <ul style="list-style-type: none"> Type: string
rest.advertised.port	If set, this is the port that will be given out to other workers to connect to. <ul style="list-style-type: none"> Type: int
rest.host.name	Hostname for the REST API. If this is set, it will only bind to this interface. <ul style="list-style-type: none"> Type: string
rest.port	Port for the REST API to listen on. <ul style="list-style-type: none"> Type: int Default: 8083
task.shutdown.graceful.timeout.ms	Amount of time to wait (milliseconds) for tasks to shutdown gracefully. This is the total amount of time, not per task. All task have shutdown triggered, then they are waited on sequentially. <ul style="list-style-type: none"> Type: long Default: 5000
streams.consumer.streams.default.stream	If set, topic names can be used in the Sink task configuration without the stream name. The defined default stream is used.
streams.producer.producer.default.stream	If set, topic names can be used in the Source task configuration without the stream name. The defined default stream is used.

Standalone Worker Configuration Options

This section describes worker parameters that are specific to standalone configurations.

The `offset.storage.file.filename` and `rest.port` parameter are specific to the standalone worker configuration. These parameters are sent in the `connect-standalone.properties` file.

Table

Parameter	Description
rest.port	Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this setting must have different values for each instance. Type: int. Default: 8083

Table (Continued)

Parameter	Description
offset.storage.file.filename	The file to store connector offsets in. By storing offsets on disk, a standalone process can be stopped and started on a single node and resume where it previously left off. Type: string. Default: empty

Distributed Worker Configuration Options

This topic describes the worker parameters that are specific to distributed configurations.

In addition to the common worker configuration options, the following are available in distributed mode. These parameters are set in the `connect-distributed.properties` file.

Table

Parameter	Description	Type	Default
group.id	A unique string that identifies the Connect cluster group that the worker belongs to.	string	""
config.storage.topic	The name of the HPE Ezmeral Data Fabric Streams topic to store connector and task configuration data in. This <i>must</i> be the same for all workers with the same group.id. For example: <code>/path/to/stream:topic-prefix-</code>	string	""
status.storage.topic	The name of the HPE Ezmeral Data Fabric Streams topic where connector and task configuration updates are stored. This <i>must</i> be the same for all workers with the same group.id.	string	""
offset.storage.topic	The HPE Ezmeral Data Fabric Streams topic to store offset data for connectors in. This <i>must</i> be the same for all workers with the same group.id. For example: <code>/path/to/stream:topic-prefix-</code>	string	""
heartbeat.interval.ms	The expected time between heartbeats to the group coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the worker's session stays active and to facilitate rebalancing when new members join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	int	3000
session.timeout.ms	The timeout used to detect failures when using Kafka's group management facilities.	int	30000
connections.max.idle.ms	Close idle connections after the number of milliseconds specified by this config.	long	540000
receive.buffer.bytes	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	int	32768
request.timeout.ms	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	int	40000

Table (Continued)

Parameter	Description	Type	Default
send.buffer.bytes	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	int	131072
worker.sync.timeout.ms	When the worker is out of sync with other workers and needs to resynchronize configurations, wait up to this amount of time before giving up, leaving the group, and waiting a backoff period before rejoining.	int	3000
worker.unsync.backoff.ms	When the worker is out of sync with other workers and fails to catch up within worker.sync.timeout.ms, leave the Connect cluster for this long before rejoining.	int	300000
client.id	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just IP/port by allowing a logical application name to be included in server-side request logging.	string	""
metadata.max.age.ms	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	long	300000
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	list	[]
metrics.num.samples	The number of samples maintained to compute metrics.	int	2
metrics.sample.window.ms	The number of samples maintained to compute metrics.	long	30000
reconnect.backoff.ms	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	long	50
retry.backoff.ms	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	long	100

Security Configuration Options

Describes Kafka Connect security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Kafka Connect REST API clients and the Kafka Connect REST Gateway. By default, Kafka Connect is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka Connect.

Starting in EEP 7.0.0 (Core 6.2.0 and KAKFA Connect 5.2.1.0) impersonation and authentication are disabled, by default, in insecure clusters.

Configure security for Kafka Connect through the security parameters in the `connect-distributed.properties` file.

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

NOTE: Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

Table

Parameter	Description	Type	Default
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. If a listener uses HTTPS, the appropriate SSL configuration parameters need to be set as well. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8082</code>	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
authentication.enable	Enable authentication. MapR supports multiple authentication methods at same time: Basic and MapR SASL	boolean	false
authentication.cookie.expiration	The option is used to specify expiration time (in seconds) for authentication cookie.	long	7200 (2 hours)
impersonation.enable	Whether or not to enable impersonation, if disabled - all manipulation will be performed from the admin of cluster user.	boolean	false
headers.file	The option is used to specify XML file that contains security and custom headers. The headers will be added to a response by Jetty server.	string	none
hadoop.http.authentication.types	A list of hadoop authentication types for MultiMechsAuthenticationHandler	list	maprauth, basic
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list.	list	<ul style="list-style-type: none"> • TLS_DHE.* • TLS_EDH.* • .*DES.* • .*MD5.* • .*RC4.*
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> • SSLv3 • TLSv1.0
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=http</code> . Leave blank to use Jetty's default.	string	none

Table (Continued)

Parameter	Description	Type	Default
ssl.key.password	The password of the private key in the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.keystore.location	Location of the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.password	The store password for the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLSv1.2
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS

SSL Security Configuration

Describes how to configure Kafka Connect security on a HPE Ezmeral Data Fabric cluster.

Secure by Default

As of Core 6.0, the Installer performs the Kafka Connect configuration for new installations. This means that:

- If core is installed as *secure*, then Kafka Connect is also installed as *secure*.
- If core is installed as *insecure*, then Kafka Connect is also installed as *insecure*.

Manually Securing Kafka Connect Only

 **CAUTION:** This configuration is *not* a typical configuration.

If you have an *insecure* HPE Ezmeral Data Fabric cluster, and you want to *secure* Kafka Connect, do the following:

1. Generate the server and client certificates.

2. Add any necessary property configurations to the `connect-distributed.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8083
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka Connect.

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8083/connectors --cacert <certificate-path>
```

Manually Unsecuring Kafka Connect

 **WARNING:** This scenario is **NOT** recommended or supported.

If you have a *secure* HPE Ezmeral Data Fabric cluster, and you want to *unsecure* Kafka Connect, do the following:

1. In the `connect-distributed.properties` configuration file, change **https://** to **http://** for the listeners and remove the **ssl.*** properties. For example:

```
listeners=http://0.0.0.0:8083
```

2. Restart Kafka Connect.

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

User Impersonation

Describes how to disable, enable, and use impersonation with Kafka Connect.

User impersonation enables Kafka Connect jobs to be submitted as a particular user. Without impersonation, Kafka Connect submits jobs as the user that started the worker

On a HPE Ezmeral Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation and PAM authentication in Kafka Connect are enabled on all types of security.

Disabling User Impersonation

To disable user impersonation, disable the PAM authentication and impersonation properties in the `opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties` file.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable impersonation, set `impersonation.enable=false`.

JDBC Connector

The topics describes the JDBC connector, drivers, and configuration parameters.

The JDBC connector allows you to import data from any relational database into HPE Ezmeral Data Fabric Streams and export data from HPE Ezmeral Data Fabric Streams to any relational database with a JDBC driver. By using JDBC, this connector can support a wide variety of databases without requiring custom code for each one.

The JDBC connector provides flexibility regarding which databases you can import data from and how that data is imported. JDBC connector implements the data copying functionality on the generic JDBC APIs, and relies on JDBC drivers to handle the database-specific implementation of those APIs.

The supported relational databases include:

- MySQL
- Oracle
- PostgreSQL
- SQLite
- SQL Server
- Hive is supported for the JDBC Source Connector

JDBC Driver

Kafka Connect for HPE Ezmeral Data Fabric Streams provides a JDBC driver jar along with the connector configuration.

The JDBC driver (`kafka-connect-jdbc`) is set up by specifying the `CLASSPATH` variable. See [Installing HPE Ezmeral Data Fabric Streams Tools](#) on page 211.

The packaged connector is installed in the `share/java/kafka-connect-jdbc` directory, relative to the installation directory.

Alternatively, to add a new driver to the `CLASSPATH`,

1. Put the classpath of the connectors in the `kafka-connect-jdbc` directory:

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<connector version>/
share/java/kafka-connect-jdbc/
```

2. Create a symlink into the `share/java/kafka-connect-jdbc/` directory.

JDBC Configuration Options

Use the following parameters to configure the Kafka Connect for HPE Ezmeral Data Fabric Streams JDBC connector; they are modified in the `quickstart-sqlite.properties` file.

Configuration Modes

In *standalone* mode, JDBC connector configuration is specified in the `quickstart-sqlite.properties` file. Additional configurations such as the offset storage location and the port for the REST interface are specified in the `connect-standalone.properties` file. See [Configuring in Standalone Mode](#) on page 4374.

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 4400 and [PUT /connectors/\(string:name\)/config](#) on page 4403 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state,

and connector offset state are specified in the **connect-distributed.properties** file. See [Configuring in Distributed Mode](#) on page 4375 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

JDBC Source Configuration Options

Table

Parameters	Description
connection.url	JDBC connection URL for the database to load. <ul style="list-style-type: none"> Type: string Default: ""
connection.user	JDBC connection user. <ul style="list-style-type: none"> Type: string Default: NULL
connection.password	JDBC connection password. <ul style="list-style-type: none"> Type: password Default: NULL
connection.attempts	Maximum number of attempts to retrieve a valid JDBC connection. <ul style="list-style-type: none"> Type: int Default: 3
connection.backoff.ms	Backoff time in milliseconds between connection attempts. <ul style="list-style-type: none"> Type: long Default: 10000
table.whitelist	List of tables to include in copying. If specified, table.blacklist may not be set. <ul style="list-style-type: none"> Type: list Default: []
table.blacklist	List of tables to exclude from copying. If specified, table.whitelist may not be set. <ul style="list-style-type: none"> Type: list Default: []
numeric.precision.mapping	Whether or not to attempt mapping <i>numeric</i> values by precision to integral types. <ul style="list-style-type: none"> Type: boolean Default: false

Table (Continued)

Parameters	Description
schema.pattern	<p>Schema pattern to fetch table metadata from the database.</p> <p>" " - Retrieves those without a schema.</p> <p>* - NULL (default) means that the schema name should not be used to narrow the search, all tables metadata would be fetched, regardless their schema.</p>
mode	<p>The mode for updating a table each time it is polled. Options include:</p> <ul style="list-style-type: none"> • bulk - perform a bulk load of the entire table each time it is polled. • incrementing - use a strictly incrementing column on each table to detect only new rows. Note that this will not detect modifications or deletions of existing rows. • timestamp - use a timestamp (or timestamp-like) column to detect new and modified rows. This assumes the column is updated with each write, and that values are monotonically incrementing, but not necessarily unique. • timestamp+incrementing - use two columns, a timestamp column that detects new and modified rows and a strictly incrementing column which provides a globally unique ID for updates so each row can be assigned a unique stream offset. • Type: string • Default: "" <p>Valid Values: [, bulk, timestamp, incrementing, timestamp+incrementing] The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an autoincrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> • Type: string • Default: "" <p> NOTE: If you are using Hive JDBC with incrementing or timestamp mode, you should set the <code>validate.non.null</code> property to false because there are no "not null" columns in Hive.</p>
timestamp.column.name	<p>The name of the timestamp column to use to detect new or modified rows. This column may not be nullable.</p> <ul style="list-style-type: none"> • Type: string • Default: ""

Table (Continued)

Parameters	Description
validate.non.null	<p>By default, the JDBC connector will validate that all incrementing and timestamp tables have NOT NULL set for the columns being used as their ID/timestamp. If the tables don't, JDBC connector will fail to start. Setting this to false will disable these checks.</p> <ul style="list-style-type: none"> Type: boolean Default: true <p> NOTE: If this parameter is false, specify exactly all columns that need to be imported to HPE Ezmeral Data Fabric Streams in the query parameter. For example instead of "query" : "select * from table", use "query" : "select col1, col2 from table"</p>
incrementing.column.name	<p>The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an auto-incrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> Type: string Default: ""
query	<p>If specified, the query to perform to select new or updated rows. Use this setting to join tables, select subsets of columns in a table, or filter data. If used, this connector will only copy data using this query – whole-table copying will be disabled. Different query modes may still be used for incremental updates, but in order to properly construct the incremental query, it must be possible to append a WHERE clause to this query (i.e. no WHERE clauses may be used). If you use a WHERE clause, it must handle incremental queries itself.</p> <ul style="list-style-type: none"> Type: string Default: ""
poll.interval.ms	<p>Frequency (milliseconds) to poll for new data in each table.</p> <ul style="list-style-type: none"> Type: int Default: 5000
batch.max.rows	<p>Maximum number of rows to include in a single batch when polling for new data. This setting can be used to limit the amount of data buffered internally in the connector.</p> <ul style="list-style-type: none"> Type: int Default: 100
table.poll.interval.ms	<p>Frequency (milliseconds) to poll for new or removed tables, which may result in updated task configurations to start polling for data in added tables or stop polling for data in removed tables.</p> <ul style="list-style-type: none"> Type: long Default: 60000

Table (Continued)

Parameters	Description
topic.prefix	<p>Prefix to prepend to table names to generate the name of the Kafka topic to publish data to, or in the case of a custom query, the full name of the topic to publish to. For example: <code>/path/to/stream:topic-prefix-</code>.</p> <ul style="list-style-type: none"> Type: string Default: ""
table.types	<p>By default, the JDBC connector will only detect tables with type TABLE from the source Database. This config allows a command separated list of table types to extract. Options include:</p> <ul style="list-style-type: none"> TABLE VIEW SYSTEM TABLE GLOBAL TEMPORARY LOCAL TEMPORARY ALIAS SYNONYM <p>Typically, TABLE or VIEW are used.</p> <ul style="list-style-type: none"> Type: list Default: TABLE
timestamp.delay.interval.ms	<p>How long to wait after a row with certain timestamp appears before it is included in the result. You may choose to add some delay to allow transactions with earlier timestamp to complete. The first execution fetches all available records (for example, starting at timestamp 0) until the current time minus the delay. Every following execution retrieves data from the last time data was fetched until the current time minus the delay.</p> <ul style="list-style-type: none"> Type: long Default: 0

JDBC Sink Configuration Options

Table

Parameters	Description
connection.url	<p>JDBC connection URL.</p> <ul style="list-style-type: none"> Type: string Default: ""
connection.user	<p>JDBC connection user.</p> <ul style="list-style-type: none"> Type: string Default: NULL

Table (Continued)

Parameters	Description
connection.password	JDBC connection password. <ul style="list-style-type: none"> Type: password Default: NULL
insert.mode	The insertion mode to use. <ul style="list-style-type: none"> INSERT - Use standard SQL INSERT statements. UPSERT - Use the appropriate upsert semantics for the target database if it is supported by the connector. For example: INSERT or IGNORE UPDATE - Use the appropriate update semantics for the target database if it is supported by the connector. For example: UPDATE Type: string Default: INSERT Valid Values: insert, upsert, update
batch.size	Specifies how many records to attempt to batch together for insertion into the destination table, when possible. <ul style="list-style-type: none"> Type: int Default: 3000 Valid Values: 0,...
table.name.format	A format string for the destination table name, which may contain <code>\${topic}</code> as a placeholder for the originating topic name. For example, <code>table_\${topic}</code> for the topic <code>orders</code> maps to the table name <code>table_orders</code> . <ul style="list-style-type: none"> Type: string Default: <code>\${topic}</code>
pk.mode	The primary key mode, also refer to <code>pk.fields</code> documentation for interplay. Supported modes are: <ul style="list-style-type: none"> none - No keys utilized. kafka - Kafka coordinates are used as the PK. record_key - Field(s) from the record key are used, which may be a primitive or a struct. record_value - Field(s) from the record value are used, which must be a struct. Type: string Default: none Valid Values: none, kafka, record_key, record_value

Table (Continued)

Parameters	Description
pk.fields	<p>List of comma-separated primary key field names. The runtime interpretation of this config depends on the pk.mode:</p> <ul style="list-style-type: none"> • none - Ignored as no fields are used as primary key in this mode. • kafka - Must be a trio representing the Kafka coordinates. Defaults to <code>__connect_topic,__connect_partition,__connect_offset</code> if empty. • record_key - If empty, all fields from the key struct will be used, otherwise used to extract the desired fields - for primitive key only a single field name must be configured. • record_value - If empty, all fields from the value struct will be used, otherwise used to extract the desired fields. • Type: list • Default: ""
fields.whitelist	<p>List of comma-separated record value field names. If empty, all fields from the record value are utilized, otherwise used to filter to the desired fields. Note: pk.fields is applied independently in the context of which field(s) form the primary key columns in the destination database, while this configuration is applicable for the other columns.</p> <ul style="list-style-type: none"> • Type: list • Default: ""
auto.create	<p>Whether to automatically create the destination table based on record schema if it is found to be missing by issuing CREATE.</p> <ul style="list-style-type: none"> • Type: boolean • Default: false
auto.evolve	<p>Whether to automatically add columns in the table schema when found to be missing relative to the record schema by issuing ALTER.</p> <ul style="list-style-type: none"> • Type: boolean • Default: false
max.retries	<p>The maximum number of times to retry on errors before failing the task.</p> <ul style="list-style-type: none"> • Type: int • Default: 10 • Valid Values: 0,..
retry.backoff.ms	<p>The time in milliseconds to wait following an error before a retry attempt is made.</p> <ul style="list-style-type: none"> • Type: int • Default: 3000 • Valid Values: 0,..

Whitelists and Custom Query JDBC Examples

This section provides common usage scenarios using whitelists and custom queries.

Using Whitelists

Use a whitelist to limit changes to a subset of tables in a MySQL database, using id and modifiedcolumns that are standard on all whitelisted tables to detect rows that have been modified. This mode is the most robust because it can combine the unique, immutable row IDs with modification timestamps to guarantee modifications are not missed even if the process dies in the middle of an incremental update query.

The following is an example of a whitelist.

NOTE: Before running this example, you need to create the stream `/kafka-connect`

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector tasks.max=10
connection.url=jdbc:mysql://mysql.example.com:3306/my_database?
user=alice&password=secret
table.whitelist=users,products,transactions
mode=timestamp+incrementing
timestamp.column.name=modified
incrementing.column.name=id
topic.prefix=/kafka-connect:mysql-

```

Using Custom Queries

Use a custom query instead of loading tables to join data from multiple tables. As long as the query does not include its own filtering, you can still use the built-in modes for incremental queries (in this case, using a timestamp column).

NOTE: This limits you to a single output per connector and because there is no table name, the topic “prefix” is actually the full topic name in this case.

The following is an example of a custom query.

NOTE: Before running this example, you need to create the stream `/kafka-connect`

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector
tasks.max=10
connection.url=jdbc:postgresql://postgres.example.com/test_db?
user=bob&password=secret&ssl=true
query=SELECT users.id,
users.name,
transactions.timestamp,
transactions.user_id,
transactions.payment FROM users JOIN transactions ON (users.id =
transactions.user_id)
mode=timestamp
timestamp.column.name=timestamp
topic.prefix=/kafka-connect:mysql-joined-data

```

Streaming Data JDBC Examples

This section provides common usage scenarios of streaming data between different databases to or from HPE Ezmeral Data Fabric Streams.

Streaming Data from HPE Ezmeral Data Fabric Streams to a MySQL Database

The following is example code for streaming data from HPE Ezmeral Data Fabric Streams stream topics to a MySQL database.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-sink-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSinkConnector",
"connection.url": "jdbc:mysql://hostname:3306/mysql_db?
user=<user>&password=<password>",
"auto.create": "true",
"topics": "/kafka-connect:topic1",
"tasks.max": "2",
"insert.mode": "insert"
}}
```

Streaming Data from a MySQL Database to HPE Ezmeral Data Fabric Streams

The following is example code for streaming data from a MySQL database to HPE Ezmeral Data Fabric Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-source-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url": "jdbc:mysql://hostname:3306/newdb?
user=<user>&password=<password>"
"mode": "incrementing",
"incrementing.column.name": "id",
"topic.prefix": "/kafka-connect:mysql-",
"tasks.max": "1"
}}
```

Streaming Data from a Hive Database to HPE Ezmeral Data Fabric Streams

The following is example code for streaming data from a Hive database to HPE Ezmeral Data Fabric Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "hive-source-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url": "jdbc:hive2://hostname:10000/
database_name;user=<user>;password=<pa
ssword>",
"mode": "bulk",
"topic.prefix": "/kafka-connect:hive-",
"tasks.max": "1"
}}
```

 **NOTE:** For a secure HPE Ezmeral Data Fabric cluster, use `next.connection.url jdbc:hive2://hostname:10000/database_name;auth=maprsasl`

Managing Kafka Connect Services

Lists the commands you use to start, stop, or restart Kafka Connect Services

Use the `maprcli node services` command with the `-action` parameter as follows:

```
maprcli node services -name kafka-connect -action start -nodes <node_list>

maprcli node services -name kafka-connect -action stop -nodes <node_list>

maprcli node services -name kafka-connect -action restart -nodes
<node_list>
```

For more information see [node services](#) on page 2181

HDFS Connector

These topics describe the Kafka Connect for HPE Ezmeral Data Fabric Streams HDFS connector, driver, and configuration parameters.

The HDFS connector allows you to export data from HPE Ezmeral Data Fabric Streams topics to file system or HDFS files in a variety of formats. In addition, Hive integration is available, which can be use to make data immediately available for querying with HiveQL.

HDFS Configuration Options

Use the following parameters to configure the Kafka Connect for HPE Ezmeral Data Fabric Streams HDFS connector.

 **NOTE:** For the HDFS connector, both Avro and Parquet files can be written.

In *standalone* mode, specify the HDFS connector configuration in the **quickstart-hdfs.properties** file. You can also configure the offset storage location and the port for the REST interface, which are specified in the **connect-standalone.properties** file. See [Configuring in Standalone Mode](#) on page 4374.

```
/opt/mapr/kafka-connect-hdfs/kafka-connect-hdfs-<version>/etc/
kafka-connect-hdfs/quickstart-hdfs.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 4400 and [PUT /connectors/\(string:name\)/config](#) on page 4403 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See [Configuring in Distributed Mode](#) on page 4375 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

Table

Parameter	Description
flush.size	Number of records written to the file system before invoking file commits. <ul style="list-style-type: none"> Type: int Default: ""

Table (Continued)

Parameter	Description
<i>hdfs.url</i>	<p>The file system connection URL. This configuration has the format of <code>maprfs://hostname:port</code> and specifies the data fabric file system to export data to.</p> <ul style="list-style-type: none"> Type: string Default: ""
<i>connect.hdfs.keytab</i>	<p>The path to the keytab file for the HDFS connector principal. This keytab file should only be readable by the connector user.</p> <ul style="list-style-type: none"> Type: string Default: ""
<i>connect.hdfs.principal</i>	<p>The principal used when the file system is using Kerberos for authentication.</p> <ul style="list-style-type: none"> Type: string Default: ""
<i>format.class</i>	<p>The format class used when writing data to the file system.</p> <ul style="list-style-type: none"> Type: string Default: "io.confluent.connect.hdfs.avro.AvroFormat" <p> NOTE: If you want to write to a Parquet set, use "io.confluent.connect.hdfs.parquet.ParquetFormat"</p>
<i>hadoop.conf.dir</i>	<p>The Hadoop configuration directory.</p> <ul style="list-style-type: none"> Type: string Default: ""
<i>hadoop.home</i>	<p>The Hadoop home directory.</p> <ul style="list-style-type: none"> Type: string Default: ""
<i>hdfs.authentication.kerberos</i>	<p>Specifies whether the file system uses Kerberos for authentication.</p> <ul style="list-style-type: none"> Type: boolean Default: false
<i>hdfs.namenode.principal</i>	<p>The Kerberos principal for CLDB.</p> <ul style="list-style-type: none"> Type: string Default: ""
<i>hive.conf.dir</i>	<p>The Hive configuration directory.</p> <ul style="list-style-type: none"> Type: string Default: ""

Table (Continued)

Parameter	Description
hive.database	The database used when the connector creates tables in Hive. <ul style="list-style-type: none"> Type: string Default: "default"
hive.home	The Hive home directory. <ul style="list-style-type: none"> Type: string Default: ""
hive.integration	Specifies whether Hive is integrated when running the connector. <ul style="list-style-type: none"> Type: boolean Default: false
hive.metastore.uris	The Hive metastore URIs. Can be an IP address or fully-qualified domain name and port of the metastore host. <ul style="list-style-type: none"> Type: string Default: ""
logs.dir	Top-level file system directory to store the write ahead logs. <ul style="list-style-type: none"> Type: string Default: "logs"
partitioner.class	The partitioner used when writing data to the file system. You can use DefaultPartitioner, which preserves the Kafka partitions; FieldPartitioner, which partitions the data to different directories according to the value of the partitioning field specified in partition.field.name; TimeBasedPartitioner, which partitions data according to the time ingested to the file system. <ul style="list-style-type: none"> Type: string Default: "io.confluent.connect.hdfs.partitionner.DefaultPartitioner"
rotate.interval.ms	The time interval (milliseconds) before invoking file commits. This configuration ensures that file commits are invoked every configured interval. This configuration is useful when data ingestion rate is low and the connector didn't write enough messages to commit files. The default value -1 means that this feature is disabled. <ul style="list-style-type: none"> Type: long Default: -1
schema.compatibility	The schema compatibility rule used when the connector is observing schema changes. The supported configurations are NONE, BACKWARD, FORWARD and FULL. <ul style="list-style-type: none"> Type: string Default: "NONE"

Table (Continued)

Parameter	Description
topics	A list of topics to use as input for the HDFS connector. <ul style="list-style-type: none"> Type: string Default: ""
topics.dir	Top-level file system directory to store the data ingested from Kafka. <ul style="list-style-type: none"> Type: string Default: "topics"
locale	The locale used when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> Type: string Default: ""
partition.duration.ms	The duration of a partition (milliseconds) used by TimeBasedPartitioner. The default value -1 means that TimeBasedPartitioner is not being used. <ul style="list-style-type: none"> Type: long Default: -1
partition.field.name	The name of the partitioning field when FieldPartitioner is used. <ul style="list-style-type: none"> Type: string Default: ""
path.format	This configuration is used to set the format of the data directories when partitioning with TimeBasedPartitioner. The format set in this configuration converts the Unix timestamp to proper directories strings. For example, if you set <code>path.format='year'=YYYY/'month'=MM/'day'=dd/'hour'=HH/</code> , the data directories will have the format <code>/year=2015/month=12/day=07/hour=15</code> <ul style="list-style-type: none"> Type: string Default: ""
shutdown.timeout.ms	Clean shutdown timeout. This makes sure that asynchronous Hive metastore updates are completed during connector shutdown. <ul style="list-style-type: none"> Type: long Default: 3000
timezone	The timezone to use when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> Type: string Default: ""
filename.offset.zero.pad.width	Sets the width to the zero-pad offsets in the file system file names. If the offsets are too short it provides fixed width filenames that can be ordered by simple lexicographic sorting. <ul style="list-style-type: none"> Type: int Default: 10

Table (Continued)

Parameter	Description
<i>kerberos.ticket.renew.period.ms</i>	The period in milliseconds to renew the Kerberos ticket. <ul style="list-style-type: none"> Type: long Default: 3600000 (milliseconds)
<i>retry.backoff.ms</i>	Used to notify Kafka Connect to retry delivering a message batch or performing recovery in case of transient exceptions. The retry backoff is in milliseconds. <ul style="list-style-type: none"> Type: long Default: 5000 (milliseconds)
<i>schema.cache.size</i>	The sized of the schema cache used in the Avro converter. <ul style="list-style-type: none"> Type: int Default: 1000
<i>storage.class</i>	The underlying storage layer. The default is MapR-FS. <ul style="list-style-type: none"> Type: string Default: "io.confluent.connect.hdfs.storage.HdfsStorage"

HDFS Examples

These examples provides sample code for streaming data to and from the file system.

Streaming Data from HPE Ezmeral Data Fabric Streams to the File System

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Streams to the file system.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
  "name": "maprfs-sink-connector",
  "config": {
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "1",
    "topics": "/kafka-connect:topic1",
    "hdfs.url": "maprfs://",
    "flush.size": "5",
    "rotate.interval.ms": "1000"
  }
}
```

Streaming Data from HPE Ezmeral Data Fabric Streams to the File System in Parquet

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Streams to the file system in Parquet.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
```

```
Accept: application/json

{
  "name": "hdfs-connector-parquet",
  "config": {
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "/kafka-connect:topic2",
    "hdfs.url": "maprfs:///",
    "format.class": "io.confluent.connect.hdfs.parquet.ParquetFormat",
    "flush.size": "3"
  }
}
```

Hive Integration

This topic describes how to integrate a Hive database with Kafka Connect for HPE Ezmeral Data Fabric Streams.

Kafka Connect for HPE Ezmeral Data Fabric Streams supports Hive integration. If a Hive database is enabled, an external Hive table is created and that can be queried via Hive shell.

NOTE: As of Kafka Connect 4.0.0 for HPE Ezmeral Data Fabric Streams Hive 2.1 is supported.

The Hive table name is constructed using a topic name in the following manner:

- In the HPE Ezmeral Data Fabric Streams topic, `/stream_path:topic-name`, the first forward slash (/) is removed, all other slashes are translated to underscores (_), and the colon (:) is translated to an underscore (_).
- All non-alphanumeric and non-underscore characters are removed from the string representing the Hive table name.

Renaming Topics for Hive usage

The following example shows a topic named `/test-12:test1` is renamed for Hive usage.

```
$ hadoop fs -ls -R /topics
drwxr-xr-x  - mapr mapr          1 2016-10-05 19:46 /topics/+tmp
drwxr-xr-x  - mapr mapr          1 2016-10-05 19:46 /topics/+tmp/
test12_test1
drwxr-xr-x  - mapr mapr          0 2016-10-05 19:50 /topics/+tmp/
test12_test1/partition=1
drwxr-xr-x  - mapr mapr          1 2016-10-05 19:46 /topics/
test12_test1
drwxr-xr-x  - mapr mapr          2 2016-10-05 19:50 /topics/
test12_test1/partition=1
-rwxr-xr-x  3 mapr mapr          241 2016-10-05 19:47 /topics/
test12_test1/partition=1/test12_test1+1+0000000078+0000000080.avro
-rwxr-xr-x  3 mapr mapr          241 2016-10-05 19:50 /topics/
test12_test1/partition=1/test12_test1+1+0000000081+0000000083.avro
```

The following query and results shows the topic data in the Hive table.

```
> select * from test12_test1;
OK
16/10/05 20:06:59 INFO mapred.FileInputFormat: Total input paths to
process : 2
18 data10 1
18 data10 1
18 data10 1
18 data10 1
```

```
18 data10 1
18 data10 1
Time taken: 0.128 seconds, Fetched: 6 row(s)

```

Streaming Data from HPE Ezmeral Data Fabric Streams to the Hive database

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Streams to the Hive database.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
  "name": "hdfs-connector-hive",
  "config": {
    "hive.integration": "true",
    "hive.database": "db3",
    "hive.conf.dir": "/opt/mapr/hive/hive-1.2/conf",
    "hive.metastore.uris": "thrift://localhost:9083",
    "schema.compatibility": "BACKWARD",
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "1",
    "topics": "/kafka-connect:topic3",
    "hdfs.url": "maprfs:///",
    "flush.size": "1"
  }
}
```

REST API

The Kafka Connect REST API for HPE Ezmeral Data Fabric Streams manages connectors.

In standalone mode, a connector request is submitted on the command line. This mode is useful for getting status information, adding and removing connectors without stopping the process, and testing and debugging.

In distributed mode, the REST API is the primary interface to the cluster. Requests can be made to any cluster member where the REST API automatically forwards requests.

Content Types

The REST API supports application/json as both the request and response entity content type. For example:

```
Accept: application/json
Content-Type: application/json
```

Status & Errors

The REST API returns standards-compliant HTTP statuses.

 **NOTE:** By default, the Kafka Connect REST API for HPE Ezmeral Data Fabric Streams service in run on port 8083.

Table

HTTP	URI	Description
GET	/connectors	Gets a list of active connectors.

Table (Continued)

HTTP	URI	Description
POST	/connectors	Creates a new connector, returning the current connector information is successful.
GET	/connectors/(string:name)	Gets information about the connector.
GET	/connectors/(string:name)/config	Gets the configuration for the connector.
PUT	/connectors/(string:name)/config	Creates a new connector using the given configuration or updates the configuration for an existing connector.
GET	/connectors/(string:name)/tasks	Gets a list of tasks current running for the connector.
DELETE	/connectors/(string:name)/	Deletes a connector, halting all tasks and deleting its configuration.
GET	/connector-plugins	Lists the connector plugins available on this worker,
POST	/connectors/(string:name)/restart	Restarts a connector and its tasks.
GET	/connectors/(string:name)/tasks/ (int:taskId)/status	Gets the status for a task.
POST	/connectors/(string:name)/tasks/ (int:number of tasks)/restart	Restarts an individual task.
PUT	/connectors/(string:name)/pause	Pauses the connector and its tasks, which stops message processing until the connector is resumed.
PUT	/connectors/(string:name)/resume	Resumes a paused connector or do nothing if the connector is not paused.
GET	/connectors/(string:name)/status	Get current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

GET /connectors

Gets a list of active connectors.

Syntax

```
http://<host>:8083/connectors
```

Request Example

```
GET /connectors HTTP/1.1 Host: connect.example.com Accept: application/json
```

Response Example

The response JSON object is in the following form:

- **connectors** (*array*) – List of connector names.

```
HTTP/1.1 200 OK Content-Type: application/json [ "my-jdbc-source",  
"my-hdfs-sink" ]
```

POST /connectors

Creates a new connector, returning the current connector information if successful.

Description

The POST request along with the parameters is used to create connectors in distributed mode.

The following table provides the parameters needed to create a new connector.

Table

Parameters	Description
name (<i>string</i>)	Name of the created connector
config (<i>map</i>)	Configuration parameters for the connector. See HDFS Connector on page 4393 and JDBC Connector on page 4383 for configuration options.
tasks (<i>array</i>)	List of active tasks generated by the connector.
tasks[i].connector (<i>string</i>)	Name of the connector that the task belongs to.
tasks[i].task (<i>int</i>)	Task ID within the connector.

Syntax

```
http://<host>:8083/connectors/?
name=<connector_name>&config=<config_parameters>
```

Request Example

```
POST /connectors HTTP/1.1 Host: connect.example.com Content-Type:
application/json Accept: application/json
{
  "name": "hdfs-sink-connector",
  "config": {
    "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "1",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  }
}
```

Response Example

The response JSON object is in the following form:

- **name** (*string*) – Name of the connector to create.
- **config** (*map*) – Configuration parameters for the connector. All values should be strings.
- **tasks** (*array*) – List of active tasks generated by the connector.

```
HTTP/1.1 201 Created Content-Type: application/json
{
  "name": "hdfs-sink-connector",
  "config":
  {
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
```

```

    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  },
  "tasks": [
    { "connector": "hdfs-sink-connector", "task": 1 },
    { "connector": "hdfs-sink-connector", "task": 2 },
    { "connector": "hdfs-sink-connector", "task": 3 }
  ]
}

```

GET /connector/(string:name)

Gets information about a specific connector.

Description

Table

Parameters	Description
name (<i>string</i>)	Name of the created connector.
config (<i>map</i>)	Configuration parameters for the connector.
tasks (<i>array</i>)	List of active tasks generated by the connector.
tasks[i].connector (<i>string</i>)	Name of the connector the task belongs to.
tasks[i].task (<i>int</i>)	Task ID within the connector.

Syntax

```
http://<host>:8083/connectors/<name>
```

Request Example

```
GET /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
Accept: application/json
```

Response Example

```

HTTP/1.1 200 OK Content-Type: application/json
{
  "name": "hdfs-sink-connector",
  "config": {
    "connector.class":
    "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"      },
  "tasks": [
    { "connector": "hdfs-sink-connector", "task": 1 },
    { "connector": "hdfs-sink-connector", "task": 2 },
    { "connector": "hdfs-sink-connector", "task": 3 }
  ]
}

```

GET /connectors/(string:name)/config
Gets the configuration for the connector.

Description

Table

Parameters	Description
config (<i>map</i>)	Configuration parameters for the connector.

Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

Request Example

```
GET /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
```

Response Example

```
HTTP/1.1 200 OK Content-Type: application/json
{
  "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
  "tasks.max": "10",
  "topics": "test-topic",
  "hdfs.url": "hdfs://fakehost:9000",
  "hadoop.conf.dir": "/opt/hadoop/conf",
  "hadoop.home": "/opt/hadoop",
  "flush.size": "100",
  "rotate.interval.ms": "1000"
}
```

PUT /connectors/(string:name)/config

Creates a new connector using the given configuration or updates the configuration for an existing connector. Returns information about the connector after the change has been made.

Description

The PUT request along with the parameters is used to create connectors in distributed mode.

Table

Parameters	Description
name (<i>string</i>)	Name of the created connector.
config (<i>map</i>)	Configuration parameters for the connector. See HDFS Connector on page 4393 and JDBC Connector on page 4383 for configuration options.
tasks (<i>array</i>)	List of active tasks generated by the connector.
tasks[i].connector (<i>string</i>)	Name of the connector that the task belongs to.
tasks[i].task (<i>int</i>)	Task ID within the connector.

Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

Request Example

```
PUT /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
{
  "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
  "tasks.max": "10",
  "topics": "test-topic",
  "hdfs.url": "hdfs://fakehost:9000",
  "hadoop.conf.dir": "/opt/hadoop/conf",
  "hadoop.home": "/opt/hadoop",
  "flush.size": "100",
  "rotate.interval.ms": "1000"
}
```

Response Example

The response JSON object is in the following form:

- config (map) – Configuration parameters for the connector. All values should be strings.

NOTE: In this example, the return status indicates that the connector was created. In the case of a configuration update, the status would be 200 OK.

```
HTTP/1.1 201 Created Content-Type: application/json
{
  "name": "hdfs-sink-connector",
  "config":
  {
    "connector.class":
    "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  },
  "tasks": [
    { "connector": "hdfs-sink-connector", "task": 1 },
    { "connector": "hdfs-sink-connector", "task": 2 },
    { "connector": "hdfs-sink-connector", "task": 3 }
  ]
}
```

GET /connectors/(string:name)/tasks

Gets a list of tasks currently running for the connector.

Description

Table

Parameters	Description
tasks (array)	List of active task configurations created by the connector.
tasks[i].id (string)	ID of the task.
tasks[i].id.connector (string)	Name of the connector that the task belongs to.
tasks[i].id.task (int)	Task ID within the connector.
tasks[i].config (map)	Configuration parameters for the task.

Syntax

```
http://<host>:8083/connectors/<connector_name>/tasks
```

Request Example

```
GET /connectors/hdfs-sink-connector/tasks HTTP/1.1 Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK
[
  {
    "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"    },
  {
    "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"    }
]
```

DELETE /connectors/(string:name)/

Deletes a connector by halting all tasks and deleting its configuration.

Syntax

```
http://<host>:8083/connectors/<connector_name>/
```

Request Example

```
DELETE /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
```

Response Example

```
HTTP/1.1 204 No Content
```

GET /connector-plugins

Lists the connector plugins available on this worker.

Syntax

```
http://<host>:8083/connector-plugins>
```

Request Example

```
GET /connector-plugins/ HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK

[
  {
    "class": "io.confluent.connect.hdfs.HdfsSinkConnector"
  },
  {
    "class": "io.confluent.connect.jdbc.JdbcSourceConnector"
  }
]
```

POST /connectors/(string:name)/restart

Restarts a connector and its tasks.

Syntax

```
http://<host>:8083/connectors/<string_name>/restart
```

Request Example

```
POST /connectors/hdfs-sink-connector/restart HTTP/1.1
Host: connect.example.com
```

Response Example

Return 409 (Conflict) if rebalance is in process.

```
HTTP/1.1 200 OK
```

GET /connectors/(string:name)/tasks/(int:taskId)/status

Gets the status for a task.

Syntax

```
http://<host>:8083/connectors/<string_name>/tasks/<task ID>/status
```

Request Example

```
GET /connectors/hdfs-sink-connector/tasks/1/status HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK

{"state": "RUNNING", "id": 1, "worker_id": "192.168.86.101:8083"}
```

POST /connectors/(string:name)/tasks/(int:number of tasks)/restart

Restarts an individual task.

Syntax

```
http://<host>:8083/connectors/<string_name>/tasks/<number of tasks>/restart
```

Request Example

```
GET /connectors/hdfs-sink-connector/tasks/1/restart HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK
```

PUT /connectors/(string:name)/pause

Pauses the connector and its tasks, which stops message processing until the connector is resumed.

Syntax

```
http://<host>:8083/connectors/<string_name>/pause
```

NOTE: This call is asynchronous and the tasks will not transition to PAUSED state at the same time.

Request Example

```
PUT /connectors/hdfs-sink-connector/pause HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 202 Accepted
```

PUT /connectors/(string:name)/resume

Resumes a paused connector or do nothing if the connector is not paused.

Syntax

```
http://<host>:8083/connectors/<string_name>/resume
```

NOTE: This call is asynchronous and the tasks will not transition to RUNNING state at the same time.

Request Example

```
PUT /connectors/hdfs-sink-connector/resume HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 202 Accepted
```

GET /connectors/{string:name}/status

Gets current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

Syntax

```
http://<host>:8083/connectors/<string_name>/status
```

Request Example

```
GET /connectors/hdfs-sink-connector/status HTTP/1.1
Host: connect.example.com
```

Response Example

The response JSON object includes the following:

- name (string) – Name of the connector
- connector (map) – Map containing connector status
- tasks[i] (map) – Map containing the task status

```
HTTP/1.1 200 OK

{
  "name": "hdfs-sink-connector",
  "connector": {
    "state": "RUNNING",
    "worker_id": "localhost:8083"
  },
  "tasks": [
    {
      "id": 0,
      "state": "RUNNING",
      "worker_id": "localhost:8083"
    },
    {
      "id": 1,
      "state": "FAILED",
      "worker_id": "localhost:8083",
      "trace":
"org.apache.kafka.common.errors.RecordTooLargeException\n"
    }
  ]
}
```

Saving Kafka Connect Configurations

Describes how Kafka Connect configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka Connect is stored in a folder with a timestamp.

- Files are saved *and* overwritten by new configuration files:
 - when upgrading from 4.1.0 to 5.1.2.
 - when upgrading from 5.1.2 to 10.0.0.

- Files are saved only (*not* overwritten):
 - when upgrading from 5.1.2 to 5.1.2.

Example

The following example shows the list of configuration files that are saved when upgrading from `mapr-kafka-connect 5.1.2 (EEP 7.0.0)` to `mapr-kafka-connect 5.1.2 (EEP 7.0.1)`:

```
ls /opt/mapr/kafka/
kafka-2.1.1  kafka-2.1.1.0.202009090438  kafkaversion

ls /opt/mapr/kafka/kafka-2.1.1.0.202009090438/config/
connect-console-sink.properties  connect-distributed.properties
connect-file-source.properties  connect-standalone.properties
connect-console-source.properties  connect-file-sink.properties
connect-log4j.properties
```

Kafka Schema Registry

Kafka Schema Registry provides a RESTful interface for storing and retrieving schemas.

Schema Registry can store and retrieve Avro schemas.

Starting in version 6.0.0, Schema Registry can store and retrieve Avro, JSON Schema, and Protobuf schemas.

When you implement Kafka Schema Registry for your data schemas, they can self-evolve for compatibility with downstream consumers.

Kafka Schema Registry acts as a standalone serving layer for metadata, interacting with both the producer and consumer. It stores schemas for keys and values of records.

Kafka Schema Registry enables you to perform the following tasks:

- Store a versioned history of all schemas.
- Provide multiple compatibility settings.
- Support schema evolution according to the configured compatibility settings and the expanded support for the schema format.
- Provide serializers that interface with Kafka clients and manage schema storage and retrieval for Kafka messages that are sent in one of the supported schema formats.

- Develop your own custom formats to use with this interface.

You can also perform these tasks:

- List schemas by subject and also list all versions of a subject (schema).
- Retrieve a schema by version or ID.
- Retrieve the latest version of a schema.
- Verify that a schema is compatible with a certain version.

Architecture

Kafka Schema Registry is designed to be distributed with a single master architecture. ZooKeeper coordinates the master election, based on the configuration. Kafka-coordinated master election is not currently supported.

HPE Ezmeral Data Fabric Streams is designed to be the durable backend for schema registry, providing a write-ahead change log for the state of schema registry and the schemas it contains.

Interoperability

Kafka Schema Registry can interface with the following components:

- Kafka Client (producer, consumer APIs)
- KStreams
- KSQL
- Kafka Connect
- Kafka REST

Performance and Scalability Impact

You can improve performance by decreasing the size of the message payload. Without Kafka Schema Registry, the message payload contains the user data and the schema metadata. With the Kafka Schema Registry, the message payload contains the user data and only the schema ID that is unique for each schema.

For scalability, you can launch Kafka Schema Registry on several nodes.

For More Information

- [Installing Kafka Schema Registry](#)
- [Confluent Schema Registry documentation](#)

Building and Deploying Kafka Schema Registry

To build and deploy Kafka Schema Registry with Maven, you must first install development versions of Kafka `common` and `rest-utils` utilities.

You can run Kafka Schema Registry instances on several cluster nodes. One node is the primary node and the other ones are secondary nodes.

Kafka Schema Registry requires ZooKeeper and HPE Ezmeral Data Fabric Streams.

The REST interface to schema registry includes a built-in Jetty server. The wrapper scripts `bin/schema-registry-start` and `bin/schema-registry-stop` are the recommended methods for starting and stopping the service.

In Apache Kafka, a schema is produced when:

- A message is produced and there is no equivalent schema in the schema registry
- A schema is created for key or value portion of the message

The associated schema subject is a “topic-key”:

- Each schema is associated with a version
- Every schema gets a globally unique ID

The consumer gets the messages’ schema using the schema ID:

```
$ curl -X GET http://localhost:8087/schemas/ids/1
{"schema": "\"string\""}

```

You can also query a schema for a given topic using the associated schema subject. For example, for `topic1` (for either key or value), `schema`, `all`, `latest`, or `specific` schema versions can be queried using the following REST commands:

```
$ curl -X GET http://localhost:8087/subjects/topic1-value/versions
[1]
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}

```

For a complete list of supported APIs, see [Confluent Schema Registry API Reference](#).

Kafka Schema Registry Limitations

Describes the limitations related to the Kafka Schema Registry.

- **No Replication Support**

Replication for Kafka Schema Registry is not supported.

- **Manually Configure Kafka REST, KSQL, and Kafka Connect to work with Schema Registry**

You must manually modify the Kafka REST, KSQL, and Kafka Connect configuration files if you want them to work with the Schema Registry.

Kafka Schema Registry Security

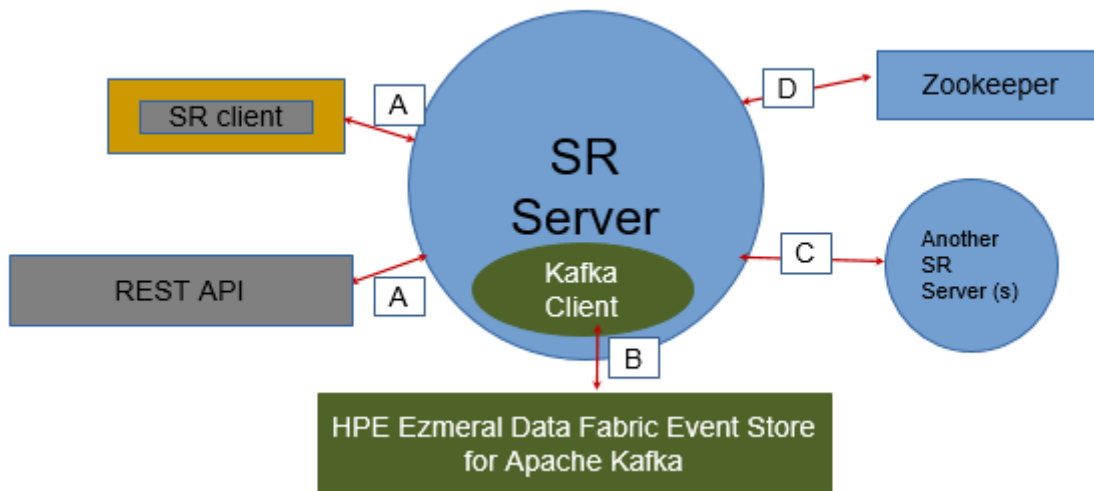

Describes security mechanisms for Kafka Schema Registry.

By default, Schema Registry is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (data-fabric SASL) enabled. Default security provides authentication, encryption, impersonation, and authorization for Schema Registry. For encryption, SSL/TLS protocols are supported.

If you install Schema Registry in an insecure cluster, you can enable security through security parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file, as described in [Security Parameters](#) on page 4413.

Schema Registry Communication Paths

The following image depicts the Schema Registry communication paths:

The following table lists the supported security mechanisms for the Schema Registry communication paths:

NOTE: Path B does not have a network connection and therefore does not need to be secured. However, impersonation works seamlessly for this path through Schema Registry Server.

Security Features	Supported Mechanisms	Communication Paths Secured	
Authentication	Data Fabric SASL (ticket-based security)	D – Schema Registry Server and ZooKeeper	
		A - Schema Registry Client and Schema Registry Server	
		C – Schema Registry Server and Schema Registry Server	
	Basic (PAM)	A - Schema Registry Client and Schema Registry Server	
		C – Schema Registry Server and Schema Registry Server	
		Cookie	A - Schema Registry Client and Schema Registry Server
Encryption	Data Fabric SASL (ticket-based security)	D - Schema Registry Server and ZooKeeper	
		A - Schema Registry Client and Schema Registry Server	
		C - Schema Registry Server and Schema Registry Server	
	SSL/TLS	A - Schema Registry Client and Schema Registry Server	
		C - Schema Registry Server and Schema Registry Server	
		Authorization	Based on filesystem permissions.
Impersonation	User impersonation		A - Schema Registry Client and Schema Registry Server
			B – Schema Registry Server to Streams for Apache Kafka
		C - Schema Registry Server and Schema Registry Server	
Auditing	Not supported	--	

Kafka Schema Registry Configuration

Describes how to configure the Kafka Schema Registry for HPE Ezmeral Data Fabric Event Store.

Set the Schema Registry configuration parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file.

schema.registry.service.id

This parameter indicates the ID of the schema registry service. The default setting for this parameter is `default_`.

See [Schema Registry Configuration Options](#) for additional Schema Registry parameters.

By default, the Schema Registry service runs on port 8087.

Security Parameters

Describes Schema Registry security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Schema Registry REST API clients and the Schema Registry Server. In secure clusters, Schema Registry is secured by default. In insecure clusters, you can enable security through the security parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file.

Requirement: Before you configure Schema Registry security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table lists the Schema Registry security parameters:

Parameter	Description	Type	Default
authorization.enable	Set 'true' or 'false' to enable or disable authorization for Schema Registry service. See Schema Registry Authorization on page 4415.	boolean	false
authentication.cookie.expiration	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
authentication.enable	Whether or not to enable authentication.	boolean	false
impersonation.enable	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See Schema Registry Impersonation on page 4416.	boolean	false
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8087</code>	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none

ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> • TLS_DHE.* • TLS_EDH.* • .DES. • .MD5. • .RC4.
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.	boolean	false
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> • SSLv3 • TLSv1.0
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file. Note: If the <code>ssl-client.xml</code> file is changed, Schema Registry must be restarted.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	empty

ssl.keystore.location	Location of the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. Note: If the ssl-client.xml file is changed, Schema Registry must be restarted.	string	empty
ssl.keystore.password	The store password for the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. Note: If the ssl-client.xml file is changed, Schema Registry must be restarted.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLS
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

Schema Registry Authorization

Describes authorization for Kafka Schema Registry.

In secure clusters, authorization is enabled by default. In insecure clusters, authorization is disabled by default.

You can enable or disable authorization for the Schema Registry in the `<schema-registry-dir>/etc/schema-registry/schema-registry.properties` file through the following option:

```
authorization.enable=[true|false]
```

Permissions

Permissions grant access to internal data in the Schema Registry, such as schemas, subjects, and server configurations. *Read* permission grants access to view data. *Modify* permission grants access to add, update, and remove data.

The following sections describe operations that require *read* and *modify* access.

NOTE: To avoid any unexpected behaviours when using Schema Registry with KSQL, Kafka Rest, Kafka Connect, or custom Java applications, both *read* and *modify* permissions are required.

REST API Operations that Require Read Access

GET /schemas/ids/{int: id}	Get the schema string identified by the input ID.
GET /subjects/	Get a list of versions registered under the specified subject.
GET /subjects/(string: subject)/versions/(versionId: version)	Get a specific version of the schema registered under this subject.
GET /subjects/(string: subject)/versions/(versionId: version)/schema	Get the avro schema for the specified version of this subject.
GET /config	Get global compatibility level.
GET /config/(string: subject)	Get compatibility level for a subject.
POST /subjects/(string: subject)	Check if a schema has already been registered under the specified subject. If so, this returns the schema string along with its globally unique identifier, its version under this subject and the subject name.
POST /compatibility/subjects/(string: subject)/versions/(versionId: version)	Test input schema against a particular version of a subject's schema for compatibility.

REST API Operations that Require Modify Access

DELETE /subjects/(string: subject)	Deletes the specified subject and its associated compatibility level if registered.
POST /subjects/(string: subject)/versions	Register a new schema under the specified subject.
DELETE /subjects/(string: subject)/versions/(versionId: version)	Deletes a specific version of the schema registered under this subject.
PUT /config	Update global compatibility level.
PUT /config/(string: subject)	Update compatibility level for the specified subject.

Schema Registry Impersonation

Describes impersonation for Kafka Schema Registry.

Impersonation authorizes the impersonated user to perform permission-sensitive operations on the Schema Registry. In secure clusters, impersonation is enabled by default. In insecure clusters, impersonation is disabled by default.

Requirement: For impersonation to work, Schema Registry authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands

run as the authenticated user instead of the Schema Registry principal. The Schema Registry principal is the user that started the Schema Registry server.

You can enable or disable impersonation for the Schema Registry in the `<schema-registry-client>/etc/schema-registry/schema-registry.properties` file through the following option:

```
impersonation.enable=[true|false]
```

[Schema Registry Authorization](#) on page 4415

Describes authorization for Kafka Schema Registry.

Kafka Schema Registry Use Cases

Describes typical use cases to register and query a schema and serialize and deserialize data.

Use Case 1: Registering and Querying a Schema for a Kafka Topic

While Kafka topics do not have a schema, having an external store that tracks this metadata for a given Kafka topic helps answer the following questions:

- What are the different events in any given Kafka topic?
- What can I put into a given Kafka topic?
- Do all Kafka events have a similar type of schema?
- How do I parse and use the data in a given Kafka topic?

Sample workflow code:

The following sample commands register and query a schema in a Kafka topic:

```
# Register a new version of a schema under the subject "Kafka-key"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
  --data '{"schema": "{\"type\": \"string\"}'}' \
  http://localhost:8087/subjects/Kafka-key/versions
  {"id":1}

# Register a new version of a schema under the subject "Kafka-value"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
  --data '{"schema": "{\"type\": \"string\"}'}' \
  http://localhost:8087/subjects/Kafka-value/versions
  {"id":1}

# List all subjects
$ curl -X GET http://localhost:8087/subjects
  ["Kafka-value", "Kafka-key"]

# List all schema versions registered under the subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions
  [1]

# Fetch a schema by globally unique id 1
$ curl -X GET http://localhost:8087/schemas/ids/1
  {"schema": "\"string\""}

```

```
# Fetch version 1 of the schema registered under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
  {"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}
# Fetch the most recently registered schema under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
  {"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}

```

Use Case 2: Serializing and Deserializing Data in a Kafka Topic

Schema Registry 5.1.2 works with the Avro format only. Schema Registry 6.0.0 works with the Avro format and also JSON Schema and Protobuf formats.

In addition to storing the schema metadata for a topic, Kafka Schema Registry also provides mechanisms for reading and writing data to a Kafka topic in supported formats.

You can plug the appropriate Serializer into the KafkaProducer to send messages to Kafka. A Serializer is available for each of the supported formats.

For Avro, use the `KafkaAvroSerializer`.

For JSON Schema, use the `KafkaJsonSchemaSerializer`.

For Protobuf, use the `KafkaProtobufSerializer`.

Currently, primitive types of `null`, `Boolean`, `Integer`, `Long`, `Float`, `Double`, `String`, `byte[]`, and the complex `IndexedRecord` type are supported.

Sending data of other types to `KafkaAvroSerializer` causes a `SerializationException` to occur. Typically, `IndexedRecord` is used for the value of the Kafka message. If used, the key of the Kafka message is often of one of the primitive types.

For example, when sending a message to a topic `t`, the schema for the key and the value is automatically registered in the Kafka Schema Registry under the subject `t-key` and `t-value`, respectively, if the compatibility test passes. The only exception is when the null type is never registered in the Kafka Schema Registry.

For consuming messages from a Kafka topic, the deserializer can be plugged analogically to the serializer.

Use Case 3: Supporting KSQL Streams or Tables in Supported formats

KSQL requires that you use the Kafka Schema Registry to create KSQL Streams or Tables in supported formats.

Schema Registry supports Avro format. Specify `VALUE_FORMAT='AVRO'` to work with topics that contain messages in Avro format.

Starting in version 6.0.0, Schema Registry supports JSON Schema and Protobuf in addition to Avro. For JSON Schema and Protobuf, specify either `VALUE_FORMAT='JSON_SR'` or `VALUE_FORMAT='PROTOBUF'` to work with topics that contain messages in JSON Schema or Protobuf format.

Sample workflow code:

The following commands create and register a schema using an Avro console producer:

```
# Create a stream
$ maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p
# Use Avro console producer to create and register a schema

```

```

/sample-stream:pageviews-avro-topic

CREATE STREAM pageviews WITH (KAFKA_TOPIC='pageviews-avro-topic',
VALUE_FORMAT='AVRO');

CREATE TABLE users WITH (KAFKA_TOPIC='users-avro-topic',
VALUE_FORMAT='AVRO',
KEY='userid');

```

Managing Kafka Schema Registry

Describes how to manage the internal stream for Kafka Schema Registry.

Schema Registry Internal Stream

By default, the `schema-registry-internal-stream` topic stores the schemas.

The `schema-registry-internal-stream` topic is located in `/apps/schema-registry/schema-registry-internal-stream`. The `kafkastore.stream` property in the `SR_CONF_DIR/schema-registry.properties` file sets the internal stream topic.

By default, the `kafkastore.stream` property is set to `/apps/schema-registry/schema-registry-internal-stream`.

The internal stream is automatically created if it does not already exist. If the internal stream already exists and has the same permissions as the default, the system returns a warning. If `kafkastore.stream` is set to a value other than the default, the system returns an error if the stream does not exist. You must explicitly set permissions on the stream you designate as the Schema Registry internal stream.

You can use Warden and `/opt/mapr/server/configure.sh` to manage and configure Kafka Schema Registry. Any time you change Schema Registry configurations, run `configure.sh` for changes to take effect.

Secure Cluster Default Permissions on the Internal Stream

By default, the internal stream is readable by all the users and writable only by the cluster administrator. For secure clusters, the default permissions are:

- `-produceperm u:$CLUSTER_ADMIN`
- `-consumeperm p`
- `-topicperm u:$CLUSTER_ADMIN`

The cluster admin is typically `mapr` or the value set for `MAPR_USER`.

Insecure Cluster Default Permissions on the Internal Stream

The stream has both read and write permissions for all users. The default permissions can be modified by means of the `maprcli stream` API. For insecure clusters, the default permissions are:

- `-produceperm p`
- `-consumeperm p`
- `-topicperm p`

Log Compaction for the Schema Registry Internal Stream

Log compaction is the process of purging messages previously published to a topic partition while retaining the latest version. Log compaction for the Schema Registry internal stream is enabled by default.

 **IMPORTANT:** Log compaction requires a gateway on the same cluster as the Schema Registry internal stream. Also, TTL should be disabled because it can interfere with log compaction.

Installing a Gateway

Run the command appropriate for your system:

- RedHat/CentOS

```
yum install mapr-gateway
```

- Ubuntu

```
apt-get install mapr-gateway
```

- SLES

```
zypper install mapr-gateway
```

Related concepts

[Log Compaction](#) on page 733

Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record.

More information

[Preparing Clusters for Log Compaction](#) on page 1443

Describes how to prepare your environment so you can use log compaction.

Enabling High Availability for Kafka Schema Registry

You can enable high availability by installing multiple instances of schema registry on the same cluster.

About this task

One node in the cluster acts as the primary instance. Only the primary instance can publish writes to the underlying Kafka log. The primary node can also manage read requests.

All other secondary nodes manage only read requests. These nodes serve registration requests indirectly by forwarding them to the current primary node and returning any response supplied by the primary node.

Procedure

1. Install schema registry on several nodes. For installation instructions, see [Installing Kafka Schema Registry](#).
2. Configure high availability for the ensemble of ZooKeeper nodes. You can find the steps for this in the [open source documentation](#), section Clustered (Multi-Server) Setup.
3. Modify the schema registry configuration file on each node to specify the `kafkastore.connection.url` property with the ZooKeeper nodes that form the HA ensemble.
4. Run the `configure.sh -R` command on each schema registry node.

Schema Registry Demos

Provides demonstrations for using Kafka Schema Registry to store and retrieve schemas.

The following topics demonstrate how to use Kafka Schema Registry to store and retrieve schemas in the supported formats:

Kafka Schema Registry Demo for Avro

Implements a Kafka Schema Registry demo example that stores and retrieves Avro schemas.

Maven Dependencies

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```

<repositories>
  <repository>
    <id>confluent</id>
    <url>http://packages.confluent.io/maven/</url>
  </repository>
  <repository>
    <id>mapr-maven</id>
    <url>https://repository.mapr.com/maven/</url>
    <releases><enabled>true</enabled></releases>
    <snapshots><enabled>true</enabled></snapshots>
  </repository>
</repositories>

```

The following dependencies are needed for Avro and Kafka:

```

<dependency>
  <groupId>org.apache.avro</groupId>
  <artifactId>avro</artifactId>
  <version>1.9.2</version>
</dependency>
<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-avro-serializer</artifactId>
  <version>5.1.2.0-mapr-700</version>
</dependency>

```

Creating a Java class that corresponds to the Avro schema

Add the following plugins to the `pom.xml` file:

- Plugin to build code:

```

<plugin>
  <groupId>org.apache.avro</groupId>
  <artifactId>avro-maven-plugin</artifactId>
  <version>1.8.2</version>
  <executions>
    <execution>
      <phase>generate-sources</phase>
      <goals>
        <goal>schema</goal>
        <goal>protocol</goal>
        <goal>idl-protocol</goal>
      </goals>
      <configuration>
        <sourceDirectory>${project.basedir}/src/main/resources/avro</
sourceDirectory>
        <stringType>String</stringType>
        <createSetters>>false</createSetters>
        <enableDecimalLogicalType>>true</enableDecimalLogicalType>
        <fieldVisibility>private</fieldVisibility>
      </configuration>
    </execution>
  </executions>
</plugin>

```

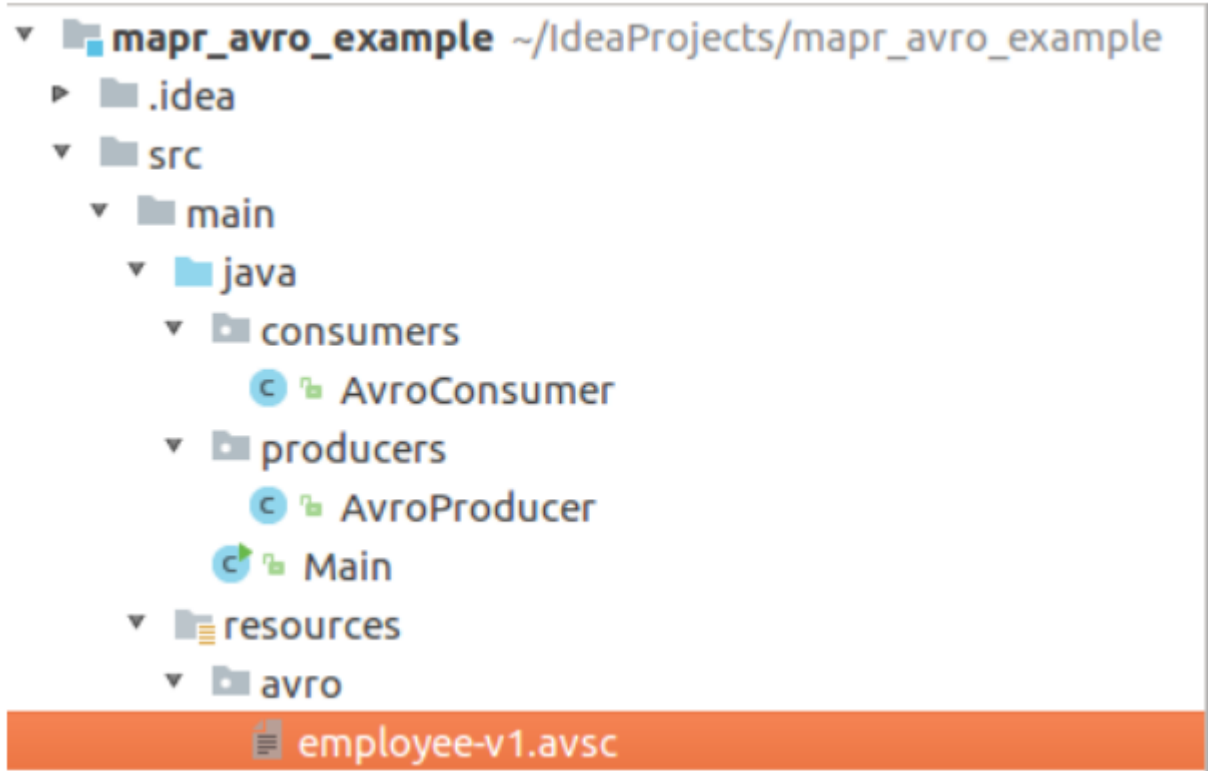

- Plugin to force the discovery of the generated classes:

```

<plugin>
  <groupId>org.codehaus.mojo</groupId>
  <artifactId>build-helper-maven-plugin</artifactId>
  <version>3.0.0</version>
  <executions>
    <execution>
      <id>add-source</id>
      <phase>generate-sources</phase>
      <goals>
        <goal>add-source</goal>
      </goals>
      <configuration>
        <sources>
          <source>target/generated-sources/avro</source>
        </sources>
      </configuration>
    </execution>
  </executions>
</plugin>

```

- Create a file with filename extension `.avsc` in the `src/main/resources` directory.

An example of an Avro schema is as follows:

```
{
  "namespace": "com.example",
  "type": "record",
  "name": "Employee",
  "doc": "Represents an Employee at a company",
  "fields": [
    {
      "name": "firstName", "type": "string", "doc": "The persons given name"
    },
    {
      "name": "lastName", "type": "string"},
    {
      "name": "age", "type": "int", "default": -1},
    {
      "name": "emails", "default": [], "type": {"type": "array", "items":
"string"}},
    {
      "name": "phoneNumber", "type": "string"}
  ]
}
```

The `Employee.class` Java class is auto-generated in the `target/classes/com/example` directory after executing the following commands:

```
$ mvn clean
$ mvn package
```

You can use this class in your program after performing these steps.

Creating an Avro Producer

1. Import the following properties for the Kafka Producer:

```
import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroSerializer;
import io.confluent.kafka.serializers.KafkaAvroSerializerConfig;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.ArrayList;
import java.util.List;
import java.util.Properties;
```

2. Configure the following properties for Event Data Streams:

```
Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    IntegerSerializer.class.getName());

// Configure the KafkaAvroSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    KafkaAvroSerializer.class.getName());

//Schema registry location.
properties.setProperty(KafkaAvroSerializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "http://localhost:8087");

KafkaProducer<Integer, Employee> producer =
    new KafkaProducer<>(properties);
```

3. The following code sends n different objects of class `Employee.java` to the topic `avro_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
Employee employee;

for (int i = 0; i < n; i++) {

    List<String> emails = new ArrayList<>();
    for (int j = 0; j < i; j++) {
        emails.add("john" + j + ".doe" + i + "@mail.com");
    }

    employee = Employee.newBuilder()
        .setFirstName("John" + i)
        .setLastName("Doe")
        .setAge(i + 5)
        .setEmails(emails)
        .setPhoneNumber("+1-202-555-" + i + i + i + i)
        .build();

    ProducerRecord<Integer, Employee> record =
        new ProducerRecord(topic, i, employee);

    producer.send(record, (recordMetadata, e) -> {
        if (e == null) {
            System.out.println("Success! ");
            System.out.println(recordMetadata.toString());
        } else {
            e.printStackTrace();
        }
    });
}

producer.flush();
producer.close();
```

Creating an Avro Consumer

1. Import the following properties for the Kafka Consumer:

```
import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroDeserializer;
import io.confluent.kafka.serializers.KafkaAvroDeserializerConfig;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.util.Collections;
import java.util.Properties;
```

2. The properties to configure are similar to the Kafka producer, only Deserializers must be used instead of Serializers. Add one more property called `KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG`:

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    IntegerDeserializer.class.getName());

//Use Kafka Avro Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    KafkaAvroDeserializer.class.getName());

//Use Specific Record or else you get Avro GenericRecord.
properties.put(KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG,
    "true");

//Schema registry location.
properties.put(KafkaAvroDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "http://localhost:8087");

KafkaConsumer<Integer, Employee> consumer =
    new KafkaConsumer<>(properties);
```

3. The following code reads objects of the `Employee.java` class from the `avro_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
consumer.subscribe(Collections.singletonList(topic));

try {
    while (true) {
        ConsumerRecords<Integer, Employee> records =
            consumer.poll(Duration.ofMillis(100));
        records.forEach(record -> {

            Employee employeeRecord = record.value();

            System.out.printf("%s %d %d %s \n", record.topic(),
                record.partition(), record.offset(), employeeRecord);
        });
    }
} finally {
    consumer.close();
}
```

Kafka Schema Registry Demo for JSON Schema

Implements a Kafka Schema Registry demo example that stores and retrieves schemas in JSON Schema format.

Maven Dependencies

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
  <repository>
    <id>confluent</id>
    <url>http://packages.confluent.io/maven/</url>
  </repository>
  <repository>
    <id>mapr-maven</id>
```

```

    <url>https://repository.mapr.com/maven/</url>
    <releases><enabled>true</enabled></releases>
    <snapshots><enabled>true</enabled></snapshots>
  </repository>
</repositories>

```

The following dependencies are needed for JSON Schema and MapR Kafka:

```

<dependency>
  <groupId>com.fasterxml.jackson.core</groupId>
  <artifactId>jackson-annotations</artifactId>
  <version>2.10.5</version>
</dependency>

<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-json-schema-serializer</artifactId>
  <version>6.0.0.0-eep-800</version>
</dependency>

```

Create a Java class that corresponds to JSON Schema

Create a Java class that includes Jackson annotations, for example:

```

import com.fasterxml.jackson.annotation.JsonProperty;

public class User {
    @JsonProperty
    public String firstName;
    @JsonProperty
    public String lastName;
    @JsonProperty
    public short age;
    public User() {}
    public User(String firstName, String lastName, short age) {
        this.firstName = firstName;
        this.lastName = lastName;
        this.age = age;
    }
    public String toString() {
        return String.format("first name: " + firstName
            + "; last name: " + lastName + "; age: " + age);
    }
}

```

Create a JSON Schema Producer

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

2. Configure the following properties for the Event Data Streams:

```
Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    IntegerSerializer.class.getName());

// Configure the KafkaJsonSchemaSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    KafkaJsonSchemaSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaJsonSchemaSerializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "http://localhost:8087");

KafkaProducer<Integer, User> producer =
    new KafkaProducer<>(properties);
```

3. Use the following code to send n different objects of class User.java to the topic json-schema_example in the /sample-stream stream:

```
String topic = "/sample-stream:json-schema_example";

for (int i = 0; i < n; i++) {
    User user = new User("John" + i, "Doe", (short) (i + 30));

    ProducerRecord<Integer, User> record =
        new ProducerRecord(topic, i, user);

    producer.send(record, (recordMetadata, e) -> {
        if (e == null) {
            System.out.println("Success!");
            System.out.println(recordMetadata.toString());
        } else {
            e.printStackTrace();
        }
    });
}

producer.flush();
producer.close();
```

Create a JSON Schema Consumer

1. Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    IntegerDeserializer.class.getName());

//Use Kafka JSON Schema Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    KafkaJsonSchemaDeserializer.class.getName());

//A class that the message value should be deserialized to.
properties.put(KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE,
    User.class.getName());

//Schema registry location.
properties.put(KafkaJsonSchemaDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "http://localhost:8087");

KafkaConsumer<Integer, User> consumer =
    new KafkaConsumer<>(properties);
```

3. Use the following code to read objects of the `User.java` class from the `json-schema_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:json-schema_example";
consumer.subscribe(Collections.singletonList(topic));

try {
    while (true) {
        ConsumerRecords<Integer, User> records =
            consumer.poll(Duration.ofMillis(100));

        records.forEach(record -> {

            User userRecord = record.value();

            System.out.printf("%s %d %d %s \n", record.topic(),
                record.partition(), record.offset(),
userRecord);
        });
    }
} finally {
    consumer.close();
}
```

Kafka Schema Registry Demo for Protobuf

Implements a Kafka Schema Registry demo example that stores and retrieves Protobuf schemas.

Maven Dependencies

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
  <repository>
    <id>confluent</id>
    <url>http://packages.confluent.io/maven/</url>
  </repository>
```

```

<repository>
  <id>mapr-maven</id>
  <url>https://repository.mapr.com/maven/</url>
  <releases><enabled>true</enabled></releases>
  <snapshots><enabled>true</enabled></snapshots>
</repository>
</repositories>

```

The following dependencies are needed for Protobuf and MapR Kafka:

```

<dependency>
  <groupId>com.google.protobuf</groupId>
  <artifactId>protobuf-java</artifactId>
  <version>3.17.3</version>
</dependency>

<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-protobuf-serializer</artifactId>
  <version>6.0.0.0-eep-800</version>
</dependency>

```

Create a Java class that corresponds to the Protobuf schema

Add the following plugin to the pom.xml file:

```

<plugin>
  <groupId>com.github.os72</groupId>
  <artifactId>protoc-jar-maven-plugin</artifactId>
  <version>3.11.4</version>
  <executions>
    <execution>
      <phase>generate-sources</phase>
      <goals>
        <goal>run</goal>
      </goals>
      <configuration>
        <inputDirectories>
          <include>src/main/resources/</include>
        </inputDirectories>
        <outputTargets>
          <outputTarget>
            <type>java</type>
            <addSources>none</addSources>
            <outputDirectory>src/main/java/</outputDirectory>
          </outputTarget>
        </outputTargets>
      </configuration>
    </execution>
  </executions>
</plugin>

```

Create a file with the .proto extension in the src/main/resources/proto directory. For example, person.proto. An example of a Protobuf schema is as follows:

```

syntax = "proto3";
package io.demo.example;
option java_outer_classname = "PersonImpl";

message Person {
  int32 id = 1;

```

```

string firstName = 2;
string lastName = 3;
string email = 4;
}

```

The `PersonImpl.class` Java class is auto-generated in the `src/main/java/io/demo/example` directory after running the following commands:

```

$ mvn clean
$ mvn package

```

You can use this class in your program to manage the class `Person.class`.

Create a Protobuf Producer

To create a Protobuf producer:

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

2. Configure the following properties for the Event Data Streams:

```

Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    IntegerSerializer.class.getName());

// Configure the KafkaProtobufSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    KafkaProtobufSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaProtobufSerializerConfig.SCHEMA_REGISTRY_URL_
CONFIG,
    "http://localhost:8087");

KafkaProducer<Integer, Person> producer =
    new KafkaProducer<>(properties);

```

- Use the following code to send n different objects of class `Person.java` to the topic `proto_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:proto_example";
Person person;

for (int i = 0; i < n; i++) {
    Person person = Person.newBuilder()
        .setId(i)
        .setFirstName("John")
        .setLastName("Doe")
        .setEmail("john" + i + ".doe@mail.com")
        .build();

    ProducerRecord<Integer, Person> record =
        new ProducerRecord(topic, i, person);

    producer.send(record, (recordMetadata, e) -> {
        if (e == null) {
            System.out.println("Success! ");
            System.out.println(recordMetadata.toString());
        } else {
            e.printStackTrace();
        }
    });
}

producer.flush();
producer.close();
```

Create a Protobuf Consumer

To create a Protobuf consumer:

- Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```

Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    IntegerDeserializer.class.getName());

//Use Kafka Protobuf Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    KafkaProtobufDeserializer.class.getName());

//A class generated by Protocol buffers that the message value should be
deserialized to.
properties.put(KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TY
PE,
    Person.class.getName());

//Schema registry location.
properties.put(KafkaProtobufDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG
'
    "http://localhost:8087");

KafkaConsumer<Integer, Person> consumer =
    new KafkaConsumer<>(properties);

```

3. Use the following code to read objects of the `Person.java` class from the `proto_example` topic in the `/sample-stream` stream:

```

String topic = "/sample-stream:proto_example";
consumer.subscribe(Collections.singletonList(topic));

try {
    while (true) {
        ConsumerRecords<Integer, Person> records =
            consumer.poll(Duration.ofMillis(100));

        records.forEach(record -> {

            Person personRecord = record.value();

            System.out.printf("%s %d %d %s \n", record.topic(),
                record.partition(), record.offset(),
                personRecord);
        });
    } finally {
        consumer.close();
    }
}

```

Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

Related Links

Spark streaming is integrated with HPE Ezmeral Data Fabric Streams for Apache Kafka.

- [MapR Event Store For Apache Kafka Clients and Tools](#)

Prerequisites for Using Structured Streaming in Spark

To deploy a structured streaming application in Spark, you must create a MapR Streams topic and install a Kafka client on all nodes in your cluster.

*Creating a MapR Streams Topic***Procedure**

- Create a MapR Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

*Installing a Kafka Client***Procedure**

- Install a `kafka-client` on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

Using Structured Streaming to Create a Word Count Application

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

*Using Apache Kafka***Example****Scala**

```
val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCount")
    .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS STRING)")
    .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split(" ")).groupBy("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
    .outputMode("complete")
    .format("console")
    .option("checkpointLocation",
checkpointLocation)
    .start()

query.awaitTermination()
```

Java

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructured
KafkaWordCount")
    .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap
.servers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
    .outputMode("complete")
    .format("console")
    .start();

query.awaitTermination();

```

Python

```

spark = SparkSession\
    .builder\
    .appName("StructuredKafkaWor
dCount")\
    .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
    .readStream\
    .format("kafka")\
    .option("kafka.bootstrap.ser
vers", bootstrapServers)\
    .option(subscribeType,
topics)\
    .load()\
    .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row

```

```

explode(
    split(lines.value, ' ')
    ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
    .writeStream\
    .outputMode('complete')\
    .format('console')\
    .start()

query.awaitTermination()

```

Using MapR Event Store for Apache Kafka

Example

For MapR Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```

var topic: String = "/user/mapr/stream:reviews"
val dfl = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
    "maprdemo:9092").option("subscribe", topic).option("group.id",
    "testgroup").option("startingOffsets",
    "earliest").option("failOnDataLoss",
    false).option("maxOffsetsPerTrigger", 1000).load()

```

Writing a Structured Spark Stream to HPE Ezmeral Data Fabric Database JSON Table

The example in this section writes a structured stream in Spark to HPE Ezmeral Data Fabric Database JSON table.

Example

To write a structured Spark stream to HPE Ezmeral Data Fabric Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

Scala

```

import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
    .writeStream
    .format(MapRDBSourceConfig.Format)
    .option(MapRDBSourceConfig.TablePath
Option, "/table/path")

```

```

        .option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
        .option(MapRDBSourceConfig.CreateTab
leOption, true)
        .option(MapRDBSourceConfig.BulkModeO
ption, true)
        .option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
        .outputMode("append")
    }

```

Java

```

import
com.mapr.db.spark.streaming.MapRDBSour
ceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
org.apache.spark.sql.streaming.DataStr
eamReader;
import
org.apache.spark.sql.streaming.DataStr
eamWriter;
import
org.apache.spark.sql.streaming.Streami
ngQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
    return df.selectExpr("CAST(value
AS STRING) as _id")
        .writeStream()
        .format(MapRDBSourceConfig
.Format())
        .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
        .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
        .option(MapRDBSourceConfig
.CreateTableOption(), true)
        .option(MapRDBSourceConfig
.BulkModeOption(), true)
        .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
        .outputMode("append");
}

```

Python

```

from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
    return df.selectExpr("CAST(value AS
STRING) as _id") \
        .writeStream \
        .format("com.mapr.db.spark.
streaming") \
        .option("checkpointLocation
", checkpoint_dir) \
        .option("tablePath",

```

```

table_path) \
    .option("idFieldPath",
"value") \
    .option("createTable",
True) \
    .option("bulkMode", True) \
    .option("sampleSize", 1000)

```

Writing a Spark Stream Word Count Application to HPE Ezmeral Data Fabric Database

The example in this section writes a Spark stream word count application to HPE Ezmeral Data Fabric Database.

Example

Scala

```

val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCou
nt")
    .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers
", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS
STRING)")
    .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
    .format(MapRDBSourceConfig.Forma
t)
    .option(MapRDBSourceConfig.Table
PathOption, resultTable)
    .option(MapRDBSourceConfig.Creat
eTableOption, true)
    .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
    .outputMode("complete")
    .start()

query.awaitTermination()

```

Java

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructuredKaf
kaWordCount")
    .getOrCreate();

```

```

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap.s
ervers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
    .format(MapRDBSourceConfig
.Format())
    .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
    .option(MapRDBSourceConfig
.CreateTableOption(), true)
    .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
    .outputMode("complete");
    .start();

query.awaitTermination();

```

Python

```

spark = SparkSession\
    .builder\
    .appName("StructuredKafkaWo
rdCount")\
    .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
    .readStream\
    .format("kafka")\
    .option("kafka.bootstrap.ser
vers", bootstrapServers)\
    .option(subscribeType,
topics)\
    .load()\
    .selectExpr("CAST(value AS
STRING)")

#Split the lines into words

```

```

words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
    split(lines.value, ' ')
    ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
    .writeStream\
    .format("com.mapr.db.spa
rk.streaming") \
    .option("tablePath",
table_path) \
    .option("createTable",
True) \
    .option("idFieldPath",
"value") \
    .outputMode('complete')\
    .start()

query.awaitTermination()

```

S3 Gateway

The S3 gateway is a service that provides an S3-compatible interface to expose data in HPE Ezmeral Data Fabric as objects. The S3 gateway manages all inbound S3 API requests to put data into and get data out of cloud storage.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

The S3 gateway can expose data generated through multiple data protocols, such as NFS, POSIX, S3, and HDFS as objects.

The HPE Ezmeral Data Fabric file system stores an object as a file. The file can be of any data type, but must have a unique name as part of the S3 API call. Files can be accessed by the S3 API requests and by HPE Ezmeral Data Fabric file interfaces. Data objects are grouped into a logical container called a bucket. A bucket correlates with a folder in HPE Ezmeral Data Fabric.

The following image shows the flow of data to and from HPE Ezmeral Data Fabric:

You can use the S3 API to create, list, or delete a bucket. You can also use it to get, put, list, or delete a data object within a bucket. The first time the S3 API accesses a file, it generates metadata. Metadata is required to fulfill the API requests.

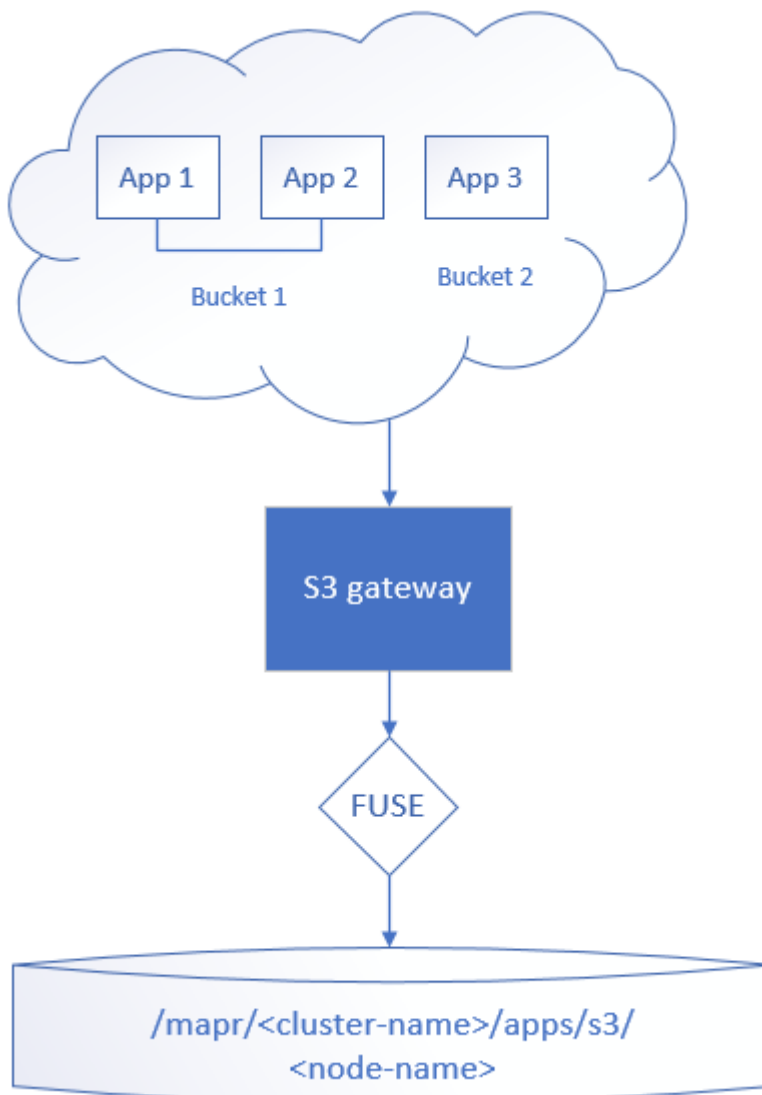

The S3 gateway also supports object notification through HPE Ezmeral Data Fabric Streams. See [Using the HPE Ezmeral Data Fabric Streams for S3 Bucket Event Notifications](#) on page 4460.

S3 Deployment Mode

The S3 gateway only supports the *Amazon S3 standalone deployment mode* because each instance of the S3 gateway can only interact with one bucket or set of buckets at a time.

When you use the S3 API in standalone mode, each S3 gateway instance must have its own back-end directory in the HPE Ezmeral Data Fabric file system. You can either map a volume mount point to the directory or use the directory path itself. An S3 instance exclusively uses the allocated directory or volume in the file system to serve an exclusive set of buckets.

The following deployment scenario shows one S3 gateway per cluster that supports multiple applications and multiple buckets with bucket sharing:

This scenario is useful if you want an application to access multiple buckets without knowing about bucket locations beforehand. The single S3 gateway instance serves all requests without having to partition any buckets.

If you need to migrate buckets to another S3 instance, you can move or copy the buckets to another directory or volume. See [AWS CLI](#). If a bucket does not exist, an application can create a bucket through any S3 gateway; however, the bucket created will only be served through the one gateway.

Authorization to Access Data

By default, the S3 gateway provides a two-tier authorization model that starts with an S3 bucket policies check at the S3 REST API level, followed by a file permissions check on the HPE Ezmeral Data Fabric.

When an S3 gateway instance receives a request from a tenant to access a bucket or object, it first checks for bucket policies that reference that particular tenant. If the tenant does not have access via the bucket policy, the request fails and no other checks are performed.

If the tenant has access via the bucket policy, the file system performs the next check using the mapped UID and GID credentials for the tenant.

[Configuring S3 Gateway](#) on page 4442 describes how to modify the type of authorization, configure tenants and credentials, and secure data.

High Availability (HA)

S3 gateway 2.0.0 and later supports working from several instances with the same mount folder on different nodes. If several instances use the same mount folder on different nodes, caching in FUSE should be disabled. For more information, see [S3 Gateway Limitations](#) on page 4463.

To implement HA, you must configure a load balancer in front of the S3 gateway instances and make the corresponding changes in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file for all instances.

If a multi-part upload feature is used, the load balancer must hash the request's source and send requests from each unique host to the same node.

After any administrative change to the S3 gateway configuration using the MinIO client (for example, to add new users, groups, policies, or notifications), you must restart all instances manually to avoid collisions on different instances.

Related Links

- For information about installation and configuration, see [Installing S3 Gateway](#) on page 214
- For a complete list of supported APIs, see [Amazon S3 documentation](#)
- For release-specific information, see [S3 Gateway Release Notes](#) on page 7346
- For information about object tiering (archiving files in the cloud), see [Data Tiering](#) on page 460.

Configuring S3 Gateway

Describes how to configure the S3 gateway.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

EEP 7.1.0 and later supports S3 gateway version 2.1.0 and higher. S3 gateway 2.2.0.0 is available starting in EEP 8.0.0.

Add the S3 gateway `superadmin` and change the deployment mode in the `minio.json` file. After you update and save the file, restart the `objectstore` service.

Global Configuration

To change the global configuration of the S3 gateway update the configuration file located in `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json`.

The configuration file for S3 gateway 2.1.0 and later differs from previous versions; it includes LDAP, distributed mode, and skip secure verification configuration updates.

S3 gateway version 2.1.0 and later configuration example

```
{
  "version": "2",
  "fsPath": "/mapr/${cluster}/apps/s3/${node}",
  "deploymentMode": "S3",
  "distributedHosts": "",
  "accessKey": "minioadmin",
  "secretKey": "minioadmin",
  "oldAccessKey": "",
  "oldSecretKey": "",

```

```

    "stsExpiry": "",
    "tlsSkipVerify": "",
    "serverStartTls": "",
    "severInsecure": ""
  }
}

```

To change the port and log path requires you to reconfigure Warden for the server node and restart the S3 gateway. Other properties require only an S3 gateway restart.

Setting the superadmin Credentials

You can configure the superadmin user name and password with properties `accessKey` and `secretKey`. If you configure the S3 gateway for the first time, then it is enough just to change them. If you would like to change the superadmin credentials on an already configured instance, you also have to set previous values `oldAccessKey` to the and `oldSecretKey`.

Setting the Deployment Mode

The deployment mode sets the type of authorization being used. The default deployment mode is S3. To change the deployment mode setting, you can edit the `deploymentMode` parameter in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file.

The S3 gateway supports the following deployment modes:

Option	Deployment Mode	Description
1	FS	<p>Enforced by file system file permissions only. The S3 bucket policy is disabled. Access is granted based on the bucket owner UID and GID (not on read, write, or execute permissions).</p> <ul style="list-style-type: none"> Configuration maps the application key or secret to a data-fabric ID. S3 policy is not used, and the policy check is skipped. Data Fabric file security validates inbound mapped UID and GID to authorize read or write file permissions. <p>You must Set the Path to Mount the file system.</p>
2	S3	<p>Enforced by S3 bucket policy only:</p> <ul style="list-style-type: none"> Access is controlled by the secret access key and the key ID. Read-write permissions and the owner of the file are ignored while granting access. <p> IMPORTANT: To prevent unauthorized access to data, upload the corresponding S3 policies after S3 gateway starts.</p>

Setting the Path to Mount the File System

If you use the FS deployment mode, you must set the path to mount the file system:

Node Type	How to Set the Path
Server node	<p>In the <code>minio.json</code> file, set the <code>fsPath</code> parameter to the file-system mount path. By default, the path is set to <code>/mapr/<clustername>/apps/s3/<nodename></code>. If you want to share existing folders with users, set the <code>fsPath</code> parameter to point to the directory with the folders that you want to share. All the folders in the directory to which <code>fsPath</code> points are accessible as buckets.</p> <p> IMPORTANT: All folders in the parent folder (<code>fsPath</code> parameter) will be accessible as buckets. Set file system permissions on folders to prevent unauthorized access to data.</p>
Edge node	<p>If you completed the edge-node installation steps, no action is required. This is because you already set the path to mount the file system when you ran the S3 gateway <code>configure.sh</code> script with the <code>--path</code> parameter.</p>

Distributed Mode

S3 gateway 2.1.0 and later supports distributed mode. S3 gateway 2.0.x does not support distributed mode.

Note the following points related to S3 gateway 2.1.0 and later in distributed mode:

- In distributed mode, instances of S3 gateway share user and policy information only, as well as locks between nodes.
- Distributed mode does not include proxy or load balancing in front of instances. You must configure and install proxy and load balancing manually.
- Distributed mode only works for S3 mode.
- Three or more nodes is recommended for S3 gateway in distributed mode. If only one node is active, the node will be in read-only mode.

To enable distributed mode for S3 gateway 2.1.0 and later:

1. Configure S3 gateway 2.1.0 or later on three or more nodes.
2. Disable caching in Fuse clients.
3. On each S3 gateway node, update the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file with the `accessKey`, `secretKey`, and `ldap`. The value for each of these properties must be identical across all the `minio.json` files.
4. On all S3 gateway 2.1.0 or later nodes, verify that the `distributedHosts` property contains the list of nodes with mount paths, for example:

```
"distributedHosts": "http(s)://HOST1:PORT1/MOUNT_PATH1 http(s)://
HOST2:PORT2/MOUNT_PATH2"
```

Note that the mount path on all nodes should target the same folder in the file system.

5. If the cluster is secure with self-signed certificates, copy the public certificates for each host to the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/certs/CAs` directory. To ignore validation of the certificates, set `"insecureSkipVerify": true`.

Setting Virtual Hosting of Buckets

You can enable the virtual hosting of buckets by setting the `domain` property in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` configuration file. For more information, see the Domain section in the [MinIO Server Config Guide](#).

Setting LDAP Integration

Set LDAP integration in the `ldap` section of the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` configuration file. For descriptions and examples of LDAP integration properties, see [MinIO LDAP documentation](#).

For LDAP integration information, refer to [Integrating S3 Gateway with LDAP/AD](#).

S3 gateway 2.1.0 and later

In S3 gateway version 2.1.0, you can only set LDAP integration in S3 mode. In S3 gateway version 2.2.0.0, you can set LDAP integration in S3 or FS mode. LDAP integration in FS mode requires that the user have a primary UID and GID. Note that you cannot assign more than one GID to a user. In FS mode, LDAP integration is handled similarly to internal users. The primary UID and GID for the LDAP user are received and injected inside the request.

```
"ldap": {
  "serverAddr": "localhost:389",
  "usernameFormat":
  "cn=%s,dc=mapr,dc=local",
  "userDNSearchBaseDN": "",
  "userDNSearchFilter": "(cn=%s)",
  "groupSearchFilter":
  "(&(objectclass=group)(member=%s))",
  "groupSearchBaseDn":
  "dc=mapr,dc=local",
  "lookUpBindDN": "",
  "lookUpBindPassword": "",
  "stsExpiry": "60h",
  "tlsSkipVerify": "on",
  "serverStartTls": "",
  "serverInsecure": "on"
}
```

S3 gateway 2.0.x

In S3 gateway version 2.0.x, only S3 mode is supported.

```
"ldap": {
  "serverAddr": "10.244.0.11:636",

  "usernameFormat": "uid=%s,ou=users,dc=example,dc=com",

  "usernameSearchFilter": "(uid=%s)",
  "groupSearchFilter": "",

  "groupSearchBaseDn": "ou=users,dc=example,dc=com",
  "usernameSearchBaseDn": "",
  "groupNameAttribute": "",
  "stsExpiry": "60h",
  "tlsSkipVerify": "on",
  "serverStartTls": "",
```

```
"severInsecure" : "off"
}
```

LDAP Limitations

- Starting from version 2.2.0.0, S3 gateway supports S3 and FS mode. In previous versions, S3 gateway only supports S3 mode (and does not support FS mode).
- LDAP/AD integration does not work with Hadoop and Spark because the HPE Ezmeral Data Fabric implementation of Hadoop and Spark does not support sessionToken.
- In S3 gateway 2.0.0, the `MINIO_IDENTITY_LDAP_SERVER_STARTTLS` property is not supported, and its value in the configuration file is ignored.

About Credentials

In the S3 world, credentials represent the application and not the identity of the end user. The application layer is responsible for end-user verification. The S3 administrator must assign S3 credentials for the application or set of applications and optionally, map those S3 credentials to a data-fabric identity.

As defined in the [Amazon S3 documentation](#), the S3 REST API uses a “key” and “secret” (in a REST-like manner) as credentials to authenticate to the underlying object storage and authorize access to data.

S3 gateway supports a multi-tenant scenario in which the S3 administrator can configure one or more credentials with the appropriate data-fabric credential mapping. The S3 administrator can assign credentials to a user and, optionally, map them to a data-fabric identity.

For an overview of tenants and multi-tenancy, see [Multitenancy on File System](#) on page 486.

Adding Credentials and Policies

You add credentials and policies from the MinIO Client (mc), which is located here: `/opt/mapr/objectstore-client/objectstore-client-<version>/util/mc`. For examples of using the MinIO Client, see the [MinIO Admin Complete Guide](#).

The only difference is that in the S3 gateway, you can additionally specify the UID and GID for the user to ensure that FS mode is working. For example:

```
mc admin user add SERVER_ALIAS USERNAME PASSWORD UID GID
```

Restarting the S3 Gateway Service

Start, restart, or stop the S3 gateway by using the command appropriate for the node:

Server Node

```
/opt/mapr/bin/maprcli node services -name objectstore -nodes
<node_name> -action [ start |
                    restart | stop ]
```

Edge Node

```
sudo /opt/mapr/objectstore-client/objectstore-client-<version>/bin/
objectstore.sh [ start |
                stop ]
```

Configuring the S3 Gateway Client

Describes how to configure the client and provides client configuration and operation examples.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

EEP 7.1.0 and later supports S3 gateway 2.1.0 and higher. S3 gateway 2.2.0.0 is available starting in EEP 8.0.0.

The S3 gateway (MinIO) client is located in `/opt/mapr/objectstore-client/objectstore-client-<version>/util/mc`.

Before you complete the tasks described in the following sections, complete the tasks in [Configuring S3 Gateway](#) on page 4442 to configure S3 gateway.

Add an S3-Compatible Service

To add an S3-compatible service, run the `mc alias set` command, as shown:

```
mc alias set ALIAS HOSTNAME ADMIN_ACCESS_KEY ADMIN_SECRET_KEY
```

Example

```
mc alias set myminio http://localhost:9000 minioadmin minioadmin
```

Create a User

You can create a user with or without a UID and GID. When you create a user without a UID and GID, the UID and GID for the S3 gateway process is used.

- **Creating a user without the UID and GID**

Run the `mc admin user add` command, as shown:

```
mc admin user add ALIAS USERNAME PASSWORD
```

Example

```
mc admin user add myminio test qwerty78
```

- **Creating a user with the UID and GID**

Run the `mc admin user add` command with the UID and GID, as shown:

```
mc admin user add ALIAS/ USERNAME PASSWORD UID GID
```

Example

```
mc admin user add myminio test qwerty78 1000 1000
```

For more information, see [MinIO Admin Complete Guide](#).

Examples

After you configure the client, you can perform bucket and object operations in S3 through Java, Python, Hadoop, and Spark.

This section provides examples with built-in users. In the examples, the default admin user, `miniadmin`, is used.

The examples demonstrate how to perform the following tasks:

- list buckets
- create a bucket
- delete a bucket
- check that a bucket exists
- list files
- upload a file
- delete a file
- check that a file exists

Java Example

See [Java Examples](#) on page 4449.

Python Example

See [Python Examples](#) on page 4453.

Hadoop Example

For Hadoop, provide the `accessKey`, `secretKey`, `host`, and `port`, as shown:

```
-Dfs.s3a.access.key=ACCESS_KEY -Dfs.s3a.secret.key=PASSWORD -Dfs.s3a.endpoint=http(s)://HOST:PORT -Dfs.s3a.path.style.access=true -Dfs.s3a.impl=org.apache.hadoop.fs.s3a.S3AFileSystem
```

Spark Example

Since Spark uses Hadoop libraries to work with S3, you must provide the `accessKey`, `secretKey`, `host`, and `port`, as shown:

```
--conf spark.hadoop.fs.s3a.access.key=ACCESS_KEY --conf spark.hadoop.fs.s3a.secret.key=PASSWORD --conf spark.hadoop.fs.s3a.endpoint=http(s)://HOST:PORT --conf spark.hadoop.fs.s3a.path.style.access=true --conf spark.hadoop.fs.s3a.impl=org.apache.hadoop.fs.s3a.S3AFileSystem
```

Java Examples

Provides examples that show you how to connect to an S3 storage service and perform bucket and object operations in Java.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

The examples provided show the code for connecting and the following operations:

- list buckets
- create a bucket
- delete a bucket
- verify that a bucket exists
- list files
- upload a file
- delete a file
- verify that a file exists

The examples have the following dependency:

```
com.amazonaws:aws-java-sdk-s3:1.11.754
```

Connection

```
package org.example.objectstore;

import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;

            .lines()
            .collect(Collectors.joining("\n"));
        System.out.println("Data:\n" + data);
    }
}

```

Python Examples

Provides examples that show you how to connect to an S3 storage service and perform bucket and object operations in Python.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

This example has the following dependencies:

- boto3 1.15.13
- botocore 1.16.26

Examples provided show the code for connecting and the following operations:

- list buckets
- create a bucket
- delete a bucket
- verify that a bucket exists
- list files

- upload a file
- delete a file
- verify that a file exists

Connection

```
import boto3
import urllib3

from botocore.client import Config
from operations import demo

if __name__ == '__main__':
    host = "http://localhost:9000"
    username = "minioadmin"
    password = "minioadmin"
    bucketName = "test"
    file = "file"

    urllib3.disable_warnings(urllib3.exceptions.InsecureRequestWarning)
    s3 = boto3.client('s3',
                      endpoint_url=host,
                      aws_access_key_id=username,
                      aws_secret_access_key=password,
                      config=Config(signature_version='s3v4'),
                      region_name='us-east-1',
                      verify=False)

    demo(s3, bucketName, file)
```

Operations

```

def check_if_file_exist(s3, bucket_name, file):
    print("Checking if file '" + file + "' exists in bucket '" +
    bucket_name + "'")
    try:
        s3.head_object(Bucket=bucket_name, Key=file)
    except ClientError as e:
        return int(e.response['Error']['Code']) != 404
    return True

```

Integrating S3 Gateway with LDAP/AD

Describes how to configure LDAP/AD for S3 gateway 2.1.0 and later.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

The S3 gateway integration uses MinIO LDAP STS to generate temporary credentials when working with an S3 endpoint through a client with a sessionToken. For complete details, see [AssumeRoleWithLDAPIdentity](#).

NOTE: LDAP/AD integration with S3 gateway 2.1.0 and later does not work with Hadoop and Spark because the HPE Ezmeral Data Fabric implementation of Hadoop and Spark does not support sessionToken.

Configuring the LDAP/AD Integration for S3 gateway

The following LDAP/AD configuration is based on an example test environment:

```

"ldap": {
  "serverAddr": "localhost:389",
  "usernameFormat": "cn=%s,dc=mapr,dc=local",
  "userDNSearchBaseDN": "",
  "userDNSearchFilter": "(cn=%s)",
  "groupSearchFilter": "(&(objectclass=group)(member=%s))",
  "groupSearchBaseDn": "dc=mapr,dc=local",
  "lookUpBindDN": "",
  "lookUpBindPassword": "",
  "stsExpiry": "60h",
  "tlsSkipVerify": "on",
  "serverStartTls": "",
  "serverInsecure": "on"
}

```

Once you have configured LDAP/AD, apply the policy to users/groups, as shown:

```
mc admin policy set myminio readwrite user="cn=admin,dc=mapr,dc=local"
```

CLI Example

Make a POST request to get credentials. In the request, replace special symbols in the password with the %HEX_VALUE of your [ASCII](#) symbol. For example, the password abc@123 translates to abc%40123.

The following example shows the POST request using the converted password:

```
curl -X POST "http://127.0.0.1:9000?
Action=AssumeRoleWithLDAPIdentity&LDAPUsername=admin&LDAPPassword=abc%40123&
Version=2011-06-15" | xmllint --format -
```

The request returns a response similar to the following example response:

```
<?xml version="1.0" encoding="UTF-8"?>
<AssumeRoleWithLDAPIdentityResponse xmlns="https://sts.amazonaws.com/doc/
2011-06-15/">
  <AssumeRoleWithLDAPIdentityResult>
    <Credentials>
      <AccessKeyId>N71HK1WE34R2D7F9FDVP</AccessKeyId>
      <SecretAccessKey>NmrkNOXA696CrblWU+eUn0NBwUv+4oUs2u8noJAA</SecretAccessKey>
      <UID/>
      <GID/>
      <Expiration>2021-04-02T23:24:59Z</Expiration>
      <SessionToken>eyJhbGciOiJIUzUxMiIsInR5cCI6IkpXVCJ9.eyJhbnNlc3NLZXkiOiJONzFIS
zFXRTM0UjJEN0Y5RkRWUCIsImV4cCI6MTYxNzQwNTg5OSwibGRhcFVzZXIiOiJjbj1hZGlpbixkY
zltYXByLGRjPWxvY2FsIn0.KY0i3DyOM-IKXi_BHADxZksC8x2PDqjDNBQVIfG-uxBKijdHrRCnw
XUy0GSGX4Q_XXvhAO4aKj5IIauDc_UceQ</SessionToken>
    </Credentials>
  </AssumeRoleWithLDAPIdentityResult>
  <ResponseMetadata>
    <RequestId>l67l69A551AF88C8</RequestId>
  </ResponseMetadata>
</AssumeRoleWithLDAPIdentityResponse>
```

Java LDAP/AD Integration Example

Demonstrates how to integrate LDAP/AD with S3 gateway version 2.1.0 and higher in Java.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

This example has the following dependencies:

- com.amazonaws:aws-java-sdk-s3:1.11.754
- com.squareup.okhttp3:okhttp:4.2.2
- com.fasterxml.jackson.dataformat:jackson-dataformat-xml:2.8.5

```
package org.example.objectstore;

import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicSessionCredentials;
import com.amazonaws.services.s3.AmazonS3;
import com.fasterxml.jackson.databind.JsonNode;
import com.fasterxml.jackson.dataformat.xml.XmlMapper;
import okhttp3.FormBody;
import okhttp3.OkHttpClient;
import okhttp3.Request;
import okhttp3.Response;
```

```

import java.io.IOException;

public class ObjectstoreLdap {
    private static final String USERNAME = "admin";
    private static final String PASSWORD = "abc@123";
    private static final String URL = "http://localhost:9000";
    private static final String BUCKET_NAME = "test";
    private static final String FILE_NAME = "file";

    public static void main(String[] args) throws IOException {
        String passwordWithoutSpecialCharacters =
replaceSpecialCharacters(PASSWORD);
        System.out.println("Your password without special characters: " +
passwordWithoutSpecialCharacters);

        AWSCredentials credentials = getTemporaryCredentials(URL, USERNAME,
passwordWithoutSpecialCharacters);
        AmazonS3 s3 = Operations.getConnection(URL, credentials, true);

        Operations.demo(s3, BUCKET_NAME, FILE_NAME);
    }

    private static String replaceSpecialCharacters(String string) {
        StringBuilder result = new StringBuilder();
        for (char val : string.toCharArray()) {
            if ((val >= 'a' && val <= 'z') || (val >= 'A' && val <= 'Z') || (val
>= '0' && val <= '9'))
                result.append(val);
            else
                result.append("%").append(Integer.toHexString(val));
        }

        return result.toString();
    }

    private static BasicSessionCredentials getTemporaryCredentials(String
url, String username, String password)
throws IOException {
        String requestUrl = new StringBuilder()
            .append(url)
            .append("?Action=AssumeRoleWithLDAPIdentity")
            .append("&LDAPUsername=")
            .append(username)
            .append("&LDAPPassword=")
            .append(password)
            .append("&Version=2011-06-15")
            .toString();

        System.out.println("POST to " + requestUrl);

        Request request = new Request.Builder()
            .url(requestUrl)
            .addHeader("User-Agent", "OkHttp Bot")
            .post(new FormBody.Builder().build())
            .build();

        OkHttpClient httpClient = new OkHttpClient();
        byte[] result;
        try (Response response = httpClient.newCall(request).execute()) {

            if (!response.isSuccessful()) throw new IOException("Unexpected code
" + response);

```

```

        result = response.body().bytes();
    }

    return parseCredentials(result);
}

private static BasicSessionCredentials parseCredentials(byte[] response)
throws IOException {
    XmlMapper mapper = new XmlMapper();

    JsonNode node = mapper.readTree(response);
    node =
node.findValue("AssumeRoleWithLDAPIdentityResult").findValue("Credentials");

    String accessKey = node.findValue("AccessKeyId").asText();
    String secretKey = node.findValue("SecretAccessKey").asText();
    String sessionId = node.findValue("SessionToken").asText();

    System.out.println();
    System.out.println("accessKey: " + accessKey);
    System.out.println("secretKey: " + secretKey);
    System.out.println("sessionId: " + sessionId);

    return new BasicSessionCredentials(accessKey, secretKey, sessionId);
}
}

```

Python LDAP/AD Integration S3 gateway

Demonstrates how to integrate LDAP/AD with S3 gateway version 2.1.0 and higher in Python.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

This example has the following dependencies:

- boto3 1.15.13
- botocore 1.16.26
- requests 2.24.0
- xmldict 0.12.0
- urllib3 1.24.3

```

import json

import boto3
import requests
import urllib3
import xmldict
from botocore.client import Config

from operations import *

def get_credentials(host, username, password):
    url = host + "?Action=AssumeRoleWithLDAPIdentity" \
              "&LDAPUsername=" + username + \
              "&LDAPPassword=" + password + "&Version=2011-06-15"

```

```

print("POST to " + url)
response = requests.post(url)
data = response.text
data = xmltodict.parse(data)
data = json.dumps(data)
data = json.loads(data)
credentials = data["AssumeRoleWithLDAPIdentityResponse"]
["AssumeRoleWithLDAPIdentityResult"]["Credentials"]
access = credentials["AccessKeyId"]
secret = credentials["SecretAccessKey"]
session = credentials["SessionToken"]
return access, secret, session

def replace_special_characters(string):
    alphanumeric = ""
    for character in string:
        if character.isalnum():
            alphanumeric += character
        else:
            alphanumeric += "%" + str(format(ord(character), "x"))

    return alphanumeric

if __name__ == '__main__':
    host = "http://localhost:9000"
    username = "admin"
    password = "abc@123"
    bucketName = "test"
    file = "file"

    passwordWithoutSpecialCharacters = replace_special_characters(password)
    print("Your password without special characters: " +
passwordWithoutSpecialCharacters)

    accessKey, secretKey, sessionToken = get_credentials(host, username,
passwordWithoutSpecialCharacters)
    print("\n")
    print("accessKey: " + accessKey)
    print("secretKey: " + secretKey)
    print("sessionToken: " + sessionToken)

    urllib3.disable_warnings(urllib3.exceptions.InsecureRequestWarning)
    s3 = boto3.client('s3',
                      endpoint_url=host,
                      aws_access_key_id=accessKey,
                      aws_secret_access_key=secretKey,
                      aws_session_token=sessionToken,
                      config=Config(signature_version='s3v4'),
                      region_name='us-east-1',
                      verify=False)

    demo(s3, bucketName, file)

```

Using the HPE Ezmeral Data Fabric Streams for S3 Bucket Event Notifications

You can use the HPE Ezmeral Data Fabric Streams to receive event notifications for buckets. For example, when an object is created in a bucket. Install the event store, create a stream and topic, and then enable notifications through the MinIO client (MC) located in `/opt/mapr/objectstore-client/objectstore-client-<version>/util/mc`.

About this task

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

Enabling Bucket Notification

About this task

NOTE: S3 gateway 2.1.0 and later does not support integration with HPE Ezmeral Data Fabric Streams. The configuration is specifically for S3 gateway 2.0.x only.

To enable bucket-notification functionality, complete the following steps:

Procedure

1. Install the `mapr-kafka*` package:

```
zypper|yum|apt-get install mapr-kafka
```

2. Create a stream and topic:

```
maprcli stream create -path /path/to/stream
maprcli stream topic create -path /path/to/stream -topic nameOfTopic
```

3. Add a new channel by using MC:

```
mc admin config set myminio notify_kafka:1 queue_dir=" "
queue_limit="0" topic="/path/to/stream:nameOfTopic"
```

4. Restart the S3 gateway.

What to do next

Now you can add events for notifications. For more information, see step 3 in this [MinIO article](#).

Reading a Topic

To read a topic:

```
/opt/mapr//kafka/kafka-<version>/bin/kafka-console-consumer.sh --topic
/path/to/stream:nameOfTopic --bootstrap-server some:9092 --from-beginning
```

AWS CLI for S3 Gateway

You can install and use the AWS Command Line Interface (CLI) with the S3 gateway.

Installing the AWS CLI

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

To install the AWS CLI on Ubuntu, RedHat/CentOS, or SLES, run:

```
pip install awscli
```

To configure the AWS CLI, use the `AWS configure` command with the values shown in the following table:

Value	Description
AWS Access Key ID	Insert the <code>accessKey</code> for the user
AWS Secret Access Key	Insert the <code>secretKey</code> for the user
Default region name	Specify 'us-west-1'
Default output format	Specify <code>json</code>

Using the AWS CLI

The following table provides examples of commands that can help you manage buckets and files.

NOTE: The `/opt/mapr/conf/ca/chain-ca.pem` file is the public certificate for the node that is generated by Data Fabric.

```
# Create a bucket and upload a file
aws s3 mb s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /opt/mapr/conf/ca/chain-ca.pem

echo "HelloS3World" > /tmp/helloS3world.txt
aws s3 cp /tmp/helloS3world.txt s3://mybucket/
helloS3world.txt --endpoint-url https://<ip-address>:9000 --ca-bundle /opt/
mapr/conf/ca/chain-ca.pem

# Move an object from one bucket to another
aws s3 mv s3://firstbucket/helloS3world.txt s3://mybucket/
helloS3world.txt --endpoint-url https://<ip-address>:9000 --ca-bundle /opt/
mapr/conf/ca/chain-ca.pem

# Delete an object from a bucket
aws s3 rm s3://mybucket/helloS3world.txt --endpoint-url https://
<ip-address>:9000 --ca-bundle /opt/mapr/conf/ca/chain-ca.pem

# Delete the bucket
aws s3 rb s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /opt/mapr/conf/ca/chain-ca.pem

# List all files in the bucket

aws s3 ls s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /opt/mapr/conf/ca/chain-ca.pem

# Show all files on the filesystem
ls -al /mapr/demo.mapr.com/apps/s3/$(hostname)/mybucket/
```

AWS CLI Limitations

If you list a folder in FS deployment mode and at least one of the files or buckets has permissions that deny access, an access-deny error is returned.

Related concepts

[Understanding the Key Store and Trust Store Files](#) on page 1724

Provides a comprehensive listing of the key store and trust store files.

Related reference

[configure.sh](#) on page 2684

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Logs for the S3 Gateway

Logs for the S3 Gateway are available after the first run. You can access logs in `/opt/mapr/objectstore-client/objectstore-client-<version>/logs/`.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

The `minio.log` is rotated daily. Logs from previous days are archived to `minio.log-<date>.gz`.

To change the level of detail (verbosity) displayed in `minio.log`, you can edit the `logLevel` field in the `minio.json` file:

```
/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json
```

Specify a number (1 through 6) to set the log verbosity level:

```
1 - Panic (less detail)
2 - Fatal
3 - Error
4 - Warning
5 - Info
6 - Debug (more detail)
```

S3 Gateway Limitations

The S3 Gateway has certain limitations and restrictions involving protocol support, object naming, and specific object and bucket APIs that are not supported.

NOTICE: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories. S3 gateway is not supported in HPE Ezmeral Data Fabric 7.0.0 onward. HPE Ezmeral Data Fabric 7.0.0 introduces a native object storage solution. For more information, see [HPE Ezmeral Data Fabric Object Store](#) on page 494.

POSIX limitations

Because the S3 gateway uses POSIX to access the data-fabric filesystem, any POSIX limitations are applicable to the S3 gateway.

FUSE-Based POSIX client limitations

If work with data is planned on different nodes, pay attention to the value (0 or 1) of the `fuse.disable.writeback` property. If caching is enabled (0), it can cause an issue with the FUSE clients. For example, if multiple FUSE clients work on the same file, writes to a file by one FUSE client might never be seen by other FUSE clients performing a read because the kernel does not update the attributes of the file unless the file is modified locally. For more information, see [Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client](#) on page 1546.

S3 gateway instance limitations

- In S3 gateway 2.0.0, for multiple instances of S3 gateway to use the same mount folder, only one instance of S3 gateway can run as the main instance; all other instances of S3 gateway must be in stand-by mode. This facilitates the simplest realization of High Availability (HA) without distributed mode.

Object name character restrictions

You cannot use object names that contain characters `^*|` are NOT supported in Windows and other file systems which do not support them.

S3 object APIs not supported

- ObjectACL (Use bucket policies instead)
- ObjectTorrent
- ObjectVersions

S3 Bucket APIs not supported

- BucketACL (Use bucket policies instead)
- BucketCORS (CORS enabled by default on all buckets for all HTTP verbs)
- BucketLifecycle (Not required for Minio erasure coded backend)
- BucketReplication (Use mc mirror instead)
- BucketVersions, BucketVersioning (Use s3git)
- BucketWebsite (Use caddy or nginx)
- BucketAnalytics, BucketMetrics, BucketLogging (Use bucket notification APIs)
- BucketRequestPayment
- BucketTagging

File deletion limitation

If you delete a file using S3 gateway, it will delete the metadata file but not the metadata directory of the file.

Oozie

IMPORTANT: This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Apache Oozie™ is a workflow scheduler system to manage Apache Hadoop jobs. Using Oozie, you can set up *workflows* that execute MapReduce applications and *coordinators* that manage workflows.

Oozie Workflow jobs are Directed Acyclical Graphs (DAGs) of actions. Oozie Coordinator jobs are recurrent Oozie Workflow jobs triggered by time (frequency) and data availability.

Oozie is integrated with the rest of the Hadoop stack and supports several types of Hadoop jobs out-of-the-box, such as Java map-reduce, Streaming map-reduce, Pig, Hive, Sqoop, and Distcp, as well as system-specific jobs, such as Java programs and shell scripts.

This section contains documentation for Oozie on the MapR Data Platform and provides all relevant details needed to use Oozie . The documentation in this section does not duplicate the documentation on the [Apache Oozie](#) site.

Configure Oozie

This topic describes how to configure Oozie.

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

To set up Oozie using a non-default administrative user (`non-mapr`), set the `yarn.resourcemanager.principal` property to the `non-mapr` user in the `yarn-site.xml` file. For more information, see [yarn-site.xml](#).

In Oozie 4.3.0, when you modify the `yarn-site.xml` file on Oozie server nodes, you must rebuild the Oozie war file to include the latest changes using one of the following two methods:

1. First method:

a. Rebuild the Oozie war files:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh hadoop
<version> /opt/mapr/hadoop/hadoop<version> -secure
```

b. Restart Oozie:

```
maprcli node services -name oozie -action restart -nodes <space
delimited list of nodes>
```

2. Second method:

- Or, for EEP 4.x and Oozie 5.1 (EEP 6.x), you can run the following command:

```
/opt/mapr/server/configure.sh -R
```

Configuring Oozie on a Secure Cluster

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

The default configuration for Oozie on a secure cluster uses [MapR tickets](#) to authenticate between the Oozie client and server. The Oozie server uses tickets to authenticate the connection between the YARN components and the JobClient embedded in the Oozie server. Starting in the EEP 4.0 release, for secure clusters, Oozie is also configured to use SSL encryption. This default configuration is in place once Oozie is installed and the security features for your cluster are enabled. See [Enabling and Disabling Security](#). No further configuration is required. See [User Impersonation for Oozie](#) to enable user impersonation for Oozie.

The sections below provide instructions to manually configure Oozie features on a secure cluster:

Oozie Server secured by default to use SSL

Starting in EEP 6.0.0, for Oozie 4.3.0 and above, Oozie server uses SSL by default for secured clusters.

1. By default, on a secure cluster, Oozie reads the `ssl-client.xml` file and configures SSL using this file.
2. If you want to use a custom SSL configuration, enable [custom secure](#) on your cluster.

Configuring the Oozie Server to use SSL (Oozie 5.1.0.0 and above)

Configure the settings necessary for enabling SSL or TLS support in the `oozie-site.xml` file.

1. Set the `oozie.https.enabled` property to `true`:

```
<property>
  <name>oozie.https.enabled</name>
  <value>true</value>
  <description>Controls whether SSL encryption is enabled.</description>
</property>

<property>
  <name>oozie.https.truststore.file</name>
  <value>/opt/mapr/conf/ssl_truststore</value>
  <description>Path to a TrustStore file.</description>
</property>

<property>
  <name>oozie.https.keystore.file</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
  <description>Path to a KeyStore file.</description>
</property>

<property>
  <name>oozie.https.keystore.pass</name>
  <value><password></value>
  <description>Password to the KeyStore.</description>
</property>
```

NOTE: To configure the Oozie for http, set the `oozie.https.enabled` property to `false`.

2. Connect to the Oozie Web UI using SSL (HTTPS):

```
https://oozie.server.hostname:11443/oozie
```

You can also encrypt the [Oozie keystore password](#). For more information, refer to the [open source documentation](#).

Configuring Oozie Clients to Use SSL (Oozie 4.3.0)

To configure the Oozie clients, follow this step:

- Specify the path to the keystore and password at `/opt/mapr/oozie/oozie-<version>/conf/oozie-client-env.sh`:

```
export
OOZIE_CLIENT_OPTS="{OOZIE_CLIENT_OPTS} -Djavax.net.ssl.trustStore=/opt/
mapr/conf/ssl_truststore"
```

Using Kerberos to Securely Authenticate Between the Oozie Client and Server

Oozie can use Kerberos to secure authentication between the Oozie client and server. The Oozie server uses the Kerberos principal and keytab information specified in the Java Authentication and Authorization (JAAS) configuration file at `/opt/mapr/conf/mapr.login.conf`. Generate a Kerberos principal of the form `http/<fqdn>@<realm>` and store the keytab in the cluster's keytab file. The default keytab file location is `/opt/mapr/conf/mapr.keytab`.

To use Kerberos authentication on a specific invocation of Oozie without modifying your client, use the `-auth KERBEROS` option when you start Oozie, as in the following example:

```
$ bin/oozie admin -status -auth KERBEROS
```

Defining a Custom Principal and Keytab File

You can use custom Kerberos principals and keytab files if you wish. To specify the locations of these custom Kerberos principals and keytab files, make the following modifications to the `oozie-site.xml` file:

- Explicitly change the authentication type to Kerberos.

```
<property>
  <name>oozie.authentication.type</name>
  <value>kerberos</value>
  <description>
    Defines authentication used for Oozie HTTP endpoint.
    Supported values are: simple | kerberos |
    #AUTHENTICATION_HANDLER_CLASSNAME#
  </description>
</property>
```

- Modify the following entries to use your custom principals and keytab. The principal takes the form `HTTP/<hostname>`, where *hostname* is the URL used by the client to connect to the server.

```

<property>
  <name>oozie.service.HadoopAccessorService.keytab.file</name>
  <value>/opt/mapr/conf/mapr.keytab</value>
  <description>
    Location of the Oozie user keytab file.
  </description>
</property>

<property>
  <name>local.realm</name>
  <value>{local.realm}</value>
  <description>
    Kerberos Realm used by Oozie and Hadoop. Using 'local.realm' aligns
    with Hadoop configuration
  </description>
</property>

<property>
  <name>oozie.service.HadoopAccessorService.kerberos.principal</name>
  <value>mapr/<hostname>@${local.realm}</value>
  <description>
    Kerberos principal for Oozie service.
  </description>
</property>

<property>
  <name>oozie.authentication.kerberos.principal</name>
  <value>HTTP/<hostname>@${local.realm}</value>
  <description>
    Indicates the Kerberos principal to be used for the HTTP endpoint.
    The principal MUST start with 'HTTP/' per the Kerberos HTTP SPNEGO
    specification.
  </description>
</property>

```

- Optional: If you plan to run Oozie actions that require talking to external services, add the `oozie.credentials.credentialclasses` to `oozie-site.xml`. For more details, see the [Oozie documentation](#).

```

<property>
  <name>oozie.credentials.credentialclasses</name>
  <value>
    hcat=org.apache.oozie.action.hadoop.HCatCredentials,
    hbase=org.apache.oozie.action.hadoop.HbaseCredentials,
    hive2=org.apache.oozie.action.hadoop.Hive2Credentials
  </value>
</property>

```

NOTE: No specific configuration is required for configuring Oozie to use data-fabric-SASL.

Disabling Cached Tokens

After a client authenticates to Oozie, the authentication token received by the client is cached in the user's home directory in the `.oozie-auth-token` file. As long as the cached token remains valid, future authentication requests from the same client use that token and succeed, even if the client's Kerberos or

credentials have expired or have been revoked. You can disable use of the cache file by using the `oozie` command-line interface with the `-Doozie.auth.token.cache false` option.

Configuring Security Headers for Web Servers for Oozie

This section describes how to configure response headers for REST API servers used in the Oozie web UI.

! **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

About the Headers File

The XML file with security headers is located at:

```
/opt/mapr/oozie/oozie-<version>/conf/security-headers.xml
```

The `security-headers.xml` file contains the following headers:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE properties SYSTEM
"http://java.sun.com/dtd/properties.dtd">
<properties>
  <comment>Security headers that is used to minimize the possibility of
cross-site scripting and other attacks</comment>
  <entry key="X-XSS-Protection">1; mode=block</entry>
  <entry key="X-Content-Type-Options">nosniff</entry>
  <entry
key="Strict-Transport-Security">max-age=31536000;includeSubDomains</entry>
  <entry key="Content-Security-Policy">default-src https:</entry>
</properties>
```

This table describes each header:

Header	Description	Default Value
X-XSS-Protection	Stops pages from loading when reflected cross-site scripting (XSS) is detected. Supported by IE, Chrome, and Safari.	1: mode=block
X-Content-Type-Options	Indicates that the MIME types advertised in the <code>Content-Type</code> headers should not be changed and should be followed.	nosniff
Strict-Transport-Security	Tells all browsers that the website should only be accessed using HTTPS instead of using HTTP.	max-age=31536000;includeSubDomains
Content-Security-Policy	Allows web-site administrators to control resources the user agent is allowed to load for a given page. This helps guard against cross-site scripting attacks (XSS).	default-src https:

Configuring Security Headers for Oozie

To enable security headers for Oozie, add the following to the `oozie-site.xml` file, and replace `<version>` with your Oozie version:

```
<property>
<name>oozie.server.response.headers</name>
<value>/opt/mapr/oozie/oozie-<version>/conf/security-headers.xml</value>
</property>
```

Configuring Custom Headers

To configure custom headers for web servers, edit the `headers.xml` file, and add `Custom-header` as follows:

```
<entry key="Custom-header">custom-value</entry>
```

Security Headers Auto-Configuration

If you install Oozie on a secure cluster (data-fabric-SASL or Kerberos) and run the following command after Oozie installation, Oozie automatically configures itself to enable security headers, and no additional action is needed:

```
/opt/mapr/server/configure.sh -R
```

Configure High Availability for Oozie

Prerequisites

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

To configure HA for Oozie on your cluster, the cluster must meet the following prerequisites:

- Your cluster must have access to a database with support for multiple concurrent connections. To prevent this database from becoming a single point of failure, the database must support HA. HA for the Oozie service works regardless of the database's HA status. See [MySQL Data Store for Oozie](#).
- To prevent the ZooKeeper service from becoming a single point of failure, your cluster must have at least 3 ZooKeeper nodes. You can still configure HA for Oozie on clusters with a single ZK node.
- Multiple nodes on the cluster must have Oozie installed. For installation instructions, see the [Installing Core and Ecosystem Components](#) on page 91.

NOTE: For greater consistency of behavior on your cluster, verify that all of the Oozie servers have the same configuration.

- A load balancer, virtual IP, or round-robin DNS set up, such as HAProxy. To prevent the load balancer from becoming a single point of failure, the load balancer must support HA.

Procedure

1. Verify that the Oozie servers are all configured to connect to the same database. Do not start Oozie.
2. On each Oozie node, edit the `oozie-site.xml` file to add the following section, which changes the results in Oozie using the Zookeeper's version of the services, overriding the default implementations:

```
<property>
  <name>oozie.services.ext</name>
  <value>
    org.apache.oozie.service.ZKLocksService,
    org.apache.oozie.service.ZKXLogStreamingService,
    org.apache.oozie.service.ZKJobsConcurrencyService,
    org.apache.oozie.service.ZKUUIDService
  </value>
</property>
```

- On each Oozie node, edit the `oozie-site.xml` file to include a comma-separated list of the host names and ports for the ZooKeeper servers. For example:

```
<property>
  <name>oozie.zookeeper.connection.string</name>
  <value>zk1:5181,zk2:5181,zk3:5181</value>
</property>
```

- On each Oozie node, edit the `oozie-site.xml` file to include the Oozie server host name:

```
<property>
  <name>oozie.http.hostname</name>
  <value><FQDN></value>
</property>
```

- On each Oozie node, edit the `oozie-site.xml` file to specify the namespace. Each Oozie server that communicates to other Oozie servers must use the same namespace:

```
<property>
  <name>oozie.zookeeper.namespace</name>
  <value>oozie</value>
</property>
```

- On each Oozie node, change the value of the `OOZIE_BASE_URL` property in the `oozie-site.xml` file to point to the load balancer or virtual IP.

```
<property>
  <name>oozie.base.url</name>
  <value>http://my.loadbalancer.hostname:<oozie_port_number>/oozie/</value>
</property>
```

The `<oozie_port_number>` depends on whether your cluster is secure.

- On all nodes, update the services line in the `warden.oozie.conf` file (stored at `/opt/mapr/conf/conf.d`; or for a fresh installation, at `/opt/mapr/oozie/oozie-<version>/conf/warden.oozie.conf`) from:

```
services=oozie:1:cldb
```

to

```
services=oozie:all:cldb
```

- Run the `configure.sh -R` command.
- Run Oozie share lib update command to make sure that all Oozie services use the latest and the same version:

```
{OOZIE_HOME}/bin/oozie admin -oozie="http(s)://
my.loadbalancer.hostname:<oozie_port_number>" -sharelibupdate
```

Configure a MySQL Data Store for Oozie

About this task

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Follow these steps to configure Oozie to use a MySQL database as the Oozie data store (instead of the default Apache Derby database). The MySQL database can also be used to support [high availability \(HA\)](#).

Procedure

1. Using the `mysql` command-line tool, create a MySQL database, user, and password for the Oozie user. For example:

```
mysql> create database oozie;
mysql> grant all privileges on oozie.* to '<oozie-user>'@'%' identified
by '<oozie-passwd>';
```

2. Stop the Oozie server:

```
maprcli node services -name oozie -action stop -nodes <node-list>
```

3. Set the following JPAService properties in the `oozie-site.xml` file: **Note:** In the JDBC URL property, use the correct hostname (where MySQL is running).

```
<property>
  <name>oozie.service.JPAService.jdbc.driver</name>
  <value>com.mysql.jdbc.Driver</value>
</property>
<property>
  <name>oozie.service.JPAService.jdbc.url</name>
  <value>jdbc:mysql://localhost:3306/oozie</value>
</property>
<property>
  <name>oozie.service.JPAService.jdbc.username</name>
  <value>oozie</value>
</property>
<property>
  <name>oozie.service.JPAService.jdbc.password</name>
  <value>oozie</value>
</property>
```

- For earlier EEP 4.1.0 versions, copy the MySQL JDBC driver `mysql-connector-java-<version>-bin.jar` file to the following directory.

```
/opt/mapr/oozie/oozie-<oozieversion>/libext
```

For EEP 4.1.0 and later, the JDBC driver file `mysql-connector-java-<version>-bin.jar` is automatically copied from the `/opt/mapr/lib/` directory to the `/opt/mapr/oozie/oozie-<oozieversion>/libext` directory.

See the [repository](#) to confirm default MySQL JDBC driver in `/opt/mapr/oozie/oozie-<oozieversion>/libext` directory is compatible with your MySQL or MariaDB version. Download and update the default JDBC driver file with the driver file that is compatible with your MySQL or Maria DB version.

- Start the Oozie server:

```
maprcli node services -name oozie -action start -nodes <node-list>
```

- Check that MySQL is now in use by looking at the contents of the `oozie.log` file. For example:

```
cat /opt/mapr/oozie/oozie-<version>/logs/oozie.log |grep mysql
2015-07-24 06:10:07,023 INFO JPAService:541 - SERVER[local.novalocal]
USER[-]
GROUP[-] TOKEN[-] APP[-] JOB[-] ACTION[-] JPA configuration:
DriverClassName=com.mysql.jdbc.Driver,Url=jdbc:mysql://localhost:3306/
oozie,Username=oozie,...
```

- To encrypt the Oozie database user password, see [Encrypt the Oozie Database User Password](#) on page 4473.

Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

About this task

-  **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Create an Oozie SQL-with-schema file to reveal the schema:

```
bin/ooziedb.sh create -sqlfile oozie.sql -run
```

For more information, see the [Apache Oozie documentation](#).

Encrypt the Oozie Database User Password

About this task

-  **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Follow these steps to encrypt the password when Oozie uses a MySQL database as the Oozie data store (instead of the default Apache Derby database).

Procedure

1. Configure Oozie to use a MySQL database as described in [Configure a MySQL Data Store for Oozie](#) on page 4472.

2. [OPTIONAL] Export the Hadoop credential store password as a system variable:

```
$ export HADOOP_CREDSTORE_PASSWORD=password
```

3. Add `oozie.service.jpaservice.jdbc.password` to the jceks keystore:

```
$ hadoop credential create
oozie.service.jpaservice.jdbc.password -provider jceks://path/to/
oozie.jceks
Enter the password:
Enter the password again:
oozie.service.jpaservice.jdbc.password has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

4. Verify that the MySQL password was added:

```
Keystore type: JCEKS
Keystore provider: SunJCE

Your keystore contains 1 entry

Alias name: oozie.service.jpaservice.jdbc.password
Creation date: Apr 11, 2018
Entry type: SecretKeyEntry
```

5. Once the jceks file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file with the path to the jceks file. The jceks path location can be `maprfs` or a local file (`local-fs`).

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>jceks://path/to/oozie.jceks</value>
</property>
```

6. Update the password property to use `*****` instead of a word-readable password:

```
<property>
  <name>oozie.service.JPAService.jdbc.password</name>
  <value>*****</value>
</property>
```

Encrypt the Oozie Keystore Password

About this task

IMPORTANT: This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Starting from Oozie 5.1.0.0, follow these steps to encrypt the keystore password when Oozie is [configured to use SSL](#).

 **NOTE:** Oozie 5.1.0.0 is configured to use SSL by default on secure clusters.

Procedure

1. [OPTIONAL] Export the Hadoop credential store password as a system variable:

```
$ export HADOOP_CREDSTORE_PASSWORD=password
```

2. Add `oozie.https.keystore.pass` to the `jceks` keystore:

```
$ hadoop credential create oozie.https.keystore.pass -provider jceks://
path/to/oozie.jceks
Enter the password:
Enter the password again:
oozie.https.keystore.pass has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

3. Once the `jceks` file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file along with the path to the `jceks` file. The `jceks` path location can be `maprfs` or a local file (`local-fs`).

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>jceks://path/to/oozie.jceks</value>
</property>
```

4. Update the `password` property to use `*****` instead of a word-readable password:

```
<property>
  <name>oozie.https.keystore.pass</name>
  <value>*****</value>
</property>
```

What to do next

 **NOTE:** You can use the same `jceks` file for storing both database and keystore passwords.

User Impersonation for Oozie

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Oozie supports *impersonation*, which enables Oozie to run jobs as a user other than the user that started the Oozie server. You can set up proxy user functionality if you want Oozie to impersonate a user from a set of hosts, or to impersonate a user that belongs to a set of groups. When you configure proxy user functionality, the proxy user can perform “doAs” operations. Add configuration properties to the `oozie-site.xml` and `core-site.xml` files to configure proxy user functionality.

Add the following configuration properties to the `oozie-site.xml` file:

- `oozie.service.ProxyUserService.proxyuser.#USER#.hosts`

- `oozie.service.ProxyUserService.proxyuser.#USER#.groups`

Replace `#USER#` with the username of the proxy that can perform “doAs” operations. For the host property, you can add a list of host names as the value. For the group property, you can add a list of groups as the value. Alternatively, you can add a wildcard character (*) as the value for host and group properties. To add multiple users, copy the property and replace `#USER#` with the proxy user name.

Host Example

```
<property>
  <name>oozie.service.ProxyUserService.proxyuser.mapr.hosts</name>
  <value>*</value>
</property>
```

Group Example

```
<property>
  <name>oozie.service.ProxyUserService.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

Add the following configuration properties to the `core-site.xml`:

- `hadoop.proxyuser.#USER#.hosts`
- `hadoop.proxyuser.#USER#.groups`

Replace `#USER#` with the username of the proxy.

When you add the host property, the proxy user can only connect from a host to impersonate a user. When you add the group property, the proxy user can impersonate any member of any group.

Host Example

```
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
</property>
```

Group Example

```
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

Updating the Oozie Shared Libraries

About this task

-  **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

You must update the Oozie shared libraries when:

- the `oozie.service.WorkflowAppService.system.libpath` property in the `oozie-site.xml` file is changed from the default value (`/oozie/share/lib`).
- a core patch is installed.

By default, the Oozie shared libraries are uploaded to the `maprfs:///oozie/share/lib` directory.

To update the Oozie shared libraries, complete the following steps:

Procedure

1. Run the following command to copy the new Oozie shared libraries to the filesystem:

```
{OOZIE_HOME}/bin/oozie-setup.sh sharelib create -fs
maprfs:/// -locallib /opt/mapr/oozie/oozie-<version>/share
```

2. Run the following command to update the Oozie classpath with the new shared libraries:

```
{OOZIE_HOME}/bin/oozie admin -sharelibupdate -oozie https://<FQDN>:11443/
oozie
```

Use Oozie

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

The following sections provide information about using Oozie:

Manage Oozie Services and Interface

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

You can manage Oozie services and the Oozie interface through the command line or Oozie Web UI.

The following sections provide information about managing Oozie:

Starting, Stopping, and Restarting Oozie Services

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

The Warden daemon starts the Oozie server automatically at installation time. You can start and stop Oozie from the command line or from the Control System. Using the `maprcli node services` command enables you to start Oozie on multiple nodes at one time.

Starting, Stopping, and Restarting Oozie using `maprcli`

Complete the following steps to start | stop | restart Oozie from the command line:

1. Make a list of nodes on which Oozie is configured.
2. Issue the `maprcli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which Oozie is configured, separated by spaces.

Example:

```
maprcli node services -name oozie -action start|stop|restart -nodes
<nodes list>
```

*Enabling the Oozie Web UI***About this task**

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

The Oozie web UI can display your job status, logs, and other related information. You must enable the Oozie Web UI after you install Oozie. However, depending on how you enable the Web UI, you may also need to perform manual steps to start the Web UI after you run `configure.sh` on the cluster.

Procedure

1. Download the Ext JS 2.2 library as a zip archive (`ext-2.2.zip`). You can download this library from the [Apache Oozie Quick Start guide](#). Search for "ExtJS 2.2" on the page to find the link.

NOTE: The Ext JS 2.2 library is required only for the Oozie Web UI. A [rewrite of the Oozie web UI](#) has been proposed in the Oozie user community.

2. Copy the Ext JS 2.2 library into the `libext` directory:

```
cp ext-2.2.zip /opt/mapr/oozie/oozie-<version>/libext/
```

3. **Applicable only for Oozie 4.X versions:** Perform one of the following options based on your preference:

- If you want the Oozie Web UI to start whenever Oozie starts or restarts, perform the following steps:
 - a. If Oozie is running, shut it down:

```
maprcli node services -name oozie -action stop -nodes <space delimited list of nodes>
```

- b. Run the `oozie-setup.sh` script, and specify the hadoop version.

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh -hadoop <version> /opt/mapr/hadoop/hadoop-<version>
```

NOTE: If you are enabling the Oozie Web UI on a secure cluster and SSL must be configured, run the command with the `-secure` option:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh -hadoop <version> /opt/mapr/hadoop/hadoop-<version> -secure
```

- If you want to manually start the Web UI when Oozie starts or restarts, perform the following steps:
 - a. If Oozie is running, shut it down:

```
maprcli node services -name oozie -action stop -nodes <space delimited list of nodes>
```

- b. Run the `oozie-setup.sh` script and specify the path to the `extjs` file.

```
cd /opt/mapr/oozie/oozie-<version>
bin/oozie-setup.sh prepare-war -extjs ~/ext-2.2.zip
```

4. Restart Oozie.

```
maprcli node services -name oozie -action restart -nodes <space
delimited list of nodes>
```

Checking the Status of Oozie

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Once Oozie is installed, you can check the status using the command line or the Oozie web console. The `<oozie_port_number>` noted in the URLs depend on whether your cluster is secure.

Check Status from Command Line

Use the `oozie admin` command:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie admin -oozie http(s)://
<oozie_node>:<oozie_port_number>/oozie -status
```

The following output indicates normal operation:

```
System mode: NORMAL
```

Check Status from the Oozie Web Console

Point your browser to `http://<oozie_node>:<oozie_port_number>/oozie`

NOTE:

- For non-secure clusters:

```
Oozie url: http://<oozie_node>:11000/oozie
```

- For secure clusters:

```
Oozie url: https://<oozie_node>:11443/oozie
```

Setup and Run Oozie Examples

About this task

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

To get familiar with Oozie, set up and try the examples.

Procedure

1. Complete the following steps to set up the examples and copy them to the cluster:

- a) Extract the oozie examples archive `oozie-examples.tar.gz`:

```
cd /opt/mapr/oozie/oozie-<version>
tar xvfz ./oozie-examples.tar.gz -C /opt/mapr/oozie/oozie-<version>/
```

- b) Copy the examples to filesystem. Run the following command as a user that has permissions to write to the specified filesystem directory:

```
hadoop fs -put examples maprfs:///user/<user_name>/examples
```

2. Complete the following steps to run the examples:

- a) Choose an example and run it with the `oozie job` command. You can use the following commands to run the following examples. The `<oozie_port_number>` depends on whether your cluster is secure.

- MapReduce

```
/opt/mapr/oozie/oozie-<version>/bin/oozie job -oozie="http://localhost:<oozie_port_number>/oozie" -config /opt/mapr/oozie/oozie-<version>/examples/apps/map-reduce/job.properties -run
```

- Spark

```
/opt/mapr/oozie/oozie-<version>/bin/oozie job -oozie="http://localhost:<oozie_port_number>/oozie" -config /opt/mapr/oozie/oozie-<version>/examples/apps/spark/job.properties -run
```

NOTE: To run the packaged Hive examples, make `/tmp` on filesystem world-writable. Set `/tmp` to `777`. Example:

```
hadoop fs -chmod -R 777 /tmp
```

If `/tmp` does not exist, create `/tmp` and then set it to `777`.

Check the Status of a Job

About this task

IMPORTANT: This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

You can check the status of a job from the command line or the Oozie Web Console.

From the command line, issue the following (substituting the job ID for the `<job id>` placeholder):

```
# /opt/mapr/oozie/oozie-<version>/bin/oozie job -info <job id>
```

To check status from the Oozie Web Console, point your browser to `http://<Oozie_node>:<oozie_port_number>/oozie` and click **All Jobs**. The `<oozie_port_number>` depends on whether your cluster is secure.

Run Hive Jobs with Oozie

! **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

You run Hive jobs with Oozie by configuring a Hive workflow.

1. **Configure a Hive workflow.** You can configure Oozie to perform a workflow by connecting to Hive Metastore or Hiveserver2.

Configure a Hive Workflow with Connection to Hive Metastore

- a. To use a metastore server for the Hive job, add the following parameter to the `hive-site.xml` file:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<IP address>:<port></value>
  <description>IP address (or fully-qualified domain name) and port
of the metastore host</description>
</property>
```

- b. Copy the edited `hive-site.xml` file to the same location as your `workflow.xml` file.
- c. If you are using the Hive-on-Tez engine, and you have changed the default `tez-site.xml` configuration, perform one of the following steps:

- Copy the `tez-site.xml` file to the same location as your `workflow.xml` file:

1. Remove the `forbidden` (forbidden for Oozie) property from `tez-site.xml`:

```
<property>
  <name>fs.defaultFS</name>
  <value>maprfs:///</value>
</property>
```

2. Make sure that you update the value for `tez.lib.uris` property after removing the `fs.defaultFS` property. For example:

```
tez.lib.uris=maprfs:///apps/tez/tez-<version>,maprfs:///apps/tez/
tez-<version>/lib
```

3. Specify the `tez-site.xml` file in the `job-xml` parameter of your workflow.
- Update `<OOZIE_HOME>/conf/action-conf/hive.xml` with the new `tez-site.xml` properties.
- d. Edit the `workflow.xml` file to include the following:
 1. Specify the `hive-site.xml` in the `job-xml` parameter.
 2. Specify the name of the script (for example, `script.q`) that contains the hive query in the `script` parameter.

- Optionally, add properties used by the Oozie launcher job. Add the prefix `oozie.launcher` to the property names.

```

<workflow-app xmlns="uri:oozie:workflow:0.2" name="hive-wf">
  <start to="hive-node"/>
  <action name="hive-node">
    <hive xmlns="uri:oozie:hive-action:0.2">
      <job-tracker>${jobTracker}</job-tracker>
      <name-node>${nameNode}</name-node>
      <prepare>
        <delete path="${nameNode}/user/${wf:user()}/${
examplesRoot}/output-data/hive"/>
        <mkdir path="${nameNode}/user/${wf:user()}/${
examplesRoot}/output-data"/>
      </prepare>
      <job-xml>hive-site.xml</job-xml>
      <!-- Add this property if you copied tez-site.xml to the
same location as your workflow.xml file -->
      <job-xml>tez-site.xml</job-xml>
      <configuration>
        <property>
          <name>mapred.job.queue.name</name>
          <value>${queueName}</value>
        </property>
      </configuration>
      <script>script.q</script>
      <param>INPUT=/user/${wf:user()}/${examplesRoot}/
input-data/table</param>
      <param>OUTPUT=/user/${wf:user()}/${examplesRoot}/
output-data/hive</param>
    </hive>
    <ok to="end"/>
    <error to="fail"/>
  </action>

  <kill name="fail">
    <message>Hive failed, error message[${
wf:errorMessage(wf:lastErrorNode())}]</message>
  </kill>
  <end name="end"/>
</workflow-app>

```

Configure a Hive Workflow with Connection to HiveServer2

- Copy the edited `hive-site.xml` file to the same location as your `workflow.xml` file.
- On a Kerberos secure cluster for Oozie 4.3.0, perform the following steps:
 - Copy the `hive-site.xml` file to the `${OOZIE_HOME}/conf/action-conf/` directory.
 - Rebuild the Oozie war file:

```

/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh
-hadoop <version> /opt/mapr/hadoop/hadoop-<version>

```

- Edit the `workflow.xml` file to include the following:
 - Specify the JDBC URL used by Beeline for connections to Hiveserver2 in the `jdbc-url` element. See [Connecting to HiveServer2](#) for details.

- Specify the name of the script (for example, `script.q`) that contains the hive query in the script element.

```
<?xml version="1.0" encoding="UTF-8"?>
<workflow-app xmlns="uri:oozie:workflow:0.5" name="hive2-wf">
  <start to="hive2-node"/>
  <action name="hive2-node">
    <hive2 xmlns="uri:oozie:hive2-action:0.1">
      <job-tracker>${jobTracker}</job-tracker>
      <name-node>${nameNode}</name-node>
      <prepare>
        <delete path="${nameNode}/user/${wf:user()}/
output-data/hive2"/>
        <mkdir path="${nameNode}/user/${wf:user()}/
output-data"/>
      </prepare>
      <configuration>
        <property>
          <name>mapred.job.queue.name</name>
          <value>${queueName}</value>
        </property>
      </configuration>
      <jdbc-url>jdbc:hive2://localhost:10000/default</
jdbc-url>
      <script>script.q</script>
      <param>INPUT=/user/${wf:user()}/input-data/table</
param>
      <param>OUTPUT=/user/${wf:user()}/output-data/hive2</
param>
    </hive2>
    <ok to="end"/>
    <error to="fail"/>
  </action>
  <kill name="fail">
    <message>Hive2 (Beeline) action failed, error message[
${wf:errorMessage(wf:lastErrorNode())}]</message>
  </kill>
  <end name="end"/>
</workflow-app>
```

Run Spark Jobs with Oozie

Prerequisites

IMPORTANT: This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Complete the following steps to configure Oozie to run Spark jobs:

Configure a Spark action:

Procedure

1. For running a Spark action through Oozie, you should be able to connect to Hive on a secure cluster. Make sure the `hive-site.xml` file that is used by Oozie has the following property set:

```
<property>
  <name>hive.metastore.sasl.enabled</name>
  <value>true</value>
</property>
```

2. To add Spark configuration files (`spark-defaults.conf`, `hive-site.xml`, etc) to a Spark action, copy the files to the `{OOZIE_HOME}/share/lib/spark/` directory.
3. If needed, update the Oozie shared libraries as described in [Updating the Oozie Shared Libraries](#) on page 4476.
4. Run pySpark using Spark Action:
 - a. Run pySpark using Spark Action by specifying `pyspark` and `py4j` zip files to the sharelib:

```
cp /{SPARK_HOME}/python/lib/ pyspark*.zip {OOZIE_HOME}/share/lib/
spark/
cp /{SPARK_HOME}/python/lib/py4j*src.zip {OOZIE_HOME}/share/lib/spark/
```

- b. Update the Oozie shared libraries as described in [Updating the Oozie Shared Libraries](#) on page 4476.
5. When you configure a Spark action in the `workflow.xml`, specify the `master` and `mode` elements of the Spark job:
 - For Spark standalone mode, specify the Spark Master URL in the `master` element. For example, if your SparkMaster URL is `spark://ubuntu2:7077`, you would replace the `<master> [SPARK MASTER URL]</master>` in the example below with `<master> spark://ubuntu2:7077</master>`.

- For Spark on YARN mode, specify `yarn-client` or `yarn-cluster` in the `master` element. For example, for `yarn-cluster` mode, you would replace `<master> [SPARK MASTER URL]</master>` with `<master>yarn</master>` and `<mode>[SPARK MODE]</mode>` with `<mode>cluster</mode>`.

Here is an example of a Spark action within a `workflow.xml` file:

```
<workflow-app xmlns='uri:oozie:workflow:0.5' name='SparkFileCopy'>
  <start to='spark-node' />
  <action name='spark-node'>
    <spark xmlns="uri:oozie:spark-action:0.1">
      <job-tracker>${jobTracker}</job-tracker>
      <name-node>${nameNode}</name-node>
      <master>[SPARK MASTER URL]</master>
      <mode>[SPARK MODE]</mode>
      <name>Spark-FileCopy</name>
      <class>org.apache.oozie.example.SparkFileCopy</class>
      <jar>${nameNode}/user/${wf:user()}/${examplesRoot}/apps/spark/lib/oozie-examples.jar</jar>
      <arg>${nameNode}/user/${wf:user()}/${examplesRoot}/input-data/text/data.txt</arg>
      <arg>${nameNode}/user/${wf:user()}/${examplesRoot}/output</arg>
    </spark>
    <ok to="end" />
    <error to="fail" />
  </action>
  <kill name="fail">
    <message>Workflow failed, error
      message[${wf:errorMessage(wf:lastErrorNode())}]
    </message>
  </kill>
  <end name='end' />
</workflow-app>
```

Oozie 5.1.0 API Changes

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Oozie 5.1.0 includes the following changes in the Web Services API. The complete documentation is available at <http://oozie.apache.org/docs/5.1.0/WebServicesAPI.html>

API	Description
Get missing dependencies	This endpoint is to show all missing dependencies of coordinator action(s).
Purge Command	Oozie admin purge command cleans up the Oozie Workflow, Coordinator, or Bundle records based on the specified parameters. The unit for parameters is days. The purge command deletes the workflow records (<code>wf=30</code>) older than 30 days, coordinator records (<code>coord=7</code>) older than 7 days, and bundle records (<code>bundle=7</code>) older than 7 days. The limit (<code>limit=10</code>) defines the number of records to be fetched at a given time. Turn on or off (<code>oldCoordAction true</code> or <code>false</code>) enables coordinator action record purging for long running coordinators. If any of these parameters are not specified, it is taken from the <code>oozie-default</code> or <code>oozie-site</code> configuration file.

Oozie 4.3.0 API Changes

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Oozie 4.3.0 includes the following changes in the Web Services API. Full documentation is available at <http://oozie.apache.org/docs/4.3.0/WebServicesAPI.html>

API	Description
Validate a local file	This endpoint is to validate a workflow, coordinator, bundle XML file.
Validate a file in file system	You can validate a workflow, coordinator, bundle XML file in file system. The XML file must already exist in file system.

Oozie Known Issues

This topic describes known issues related to Oozie.

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Spark Oozie Share Library Update Required if Core Patch Applied

If you installed a Core patch for EEP version 6.3.0, 6.3.1, or 7.0.0, the Spark Oozie Share Lib must be updated with the `maprbuildversion` JAR either manually or through an Oozie upgrade.

- When you upgrade to Oozie in EEP 6.3.2, 7.0.1, or later and run `/opt/mapr/server/configure.sh -R`, the `maprbuildversion` JAR is automatically copied from `$MAPR_HOME/lib` to `$OOZIE_HOME/share/lib/spark`.
- Alternatively, you can manually copy the `maprbuildversion` JAR from `$MAPR_HOME/lib` to `$OOZIE_HOME/share/lib/spark` and then run `/opt/mapr/server/configure.sh -R`.

Oozie Share Library Update Required if Core Patch Applied

After a core patch installation, update the Oozie shared libraries under the `maprfs` directory, as described in [Updating the Oozie Shared Libraries](#) on page 4476.

Pig

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Apache Pig™ is a platform for analyzing large data sets. Apache Pig™ is a high-level language for expressing data analysis programs coupled with an infrastructure to evaluate these programs. The infrastructure layer consists of a compiler that produces sequences of Map-Reduce programs. The language layer consists of a textual language called *Pig Latin*.

The following sections provide documentation about installing, upgrading, configuring and using Pig. You can also refer to the documentation available on the [Apache Pig](#) website.

Configure Pig

About this task

! **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Pig runs in MapReduce mode by default. If you want to run Pig in local mode (`pig -x local`), add the following properties to the `/opt/mapr/pig/pig-<version>/conf/pig.properties` file:

```
fs.file.impl=org.apache.hadoop.fs.LocalFileSystem
io.file.buffer.size=4096
```

The `io.file.buffer.size` property defines how much data is buffered during read and write operations. This value defaults to `-1`, which causes Pig to fail if the local filesystem is used.

Use Pig

! **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Once Pig is installed, the executable is located in `/opt/mapr/pig/pig-<version>/bin/pig`.

The following topics provide information about using Pig. You can also refer to the documentation available on the [Apache Pig](#) website.

Get Started with Pig

About this task

! **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

In this tutorial, we will use Pig to run a MapReduce application that counts the words in the `/in/constitution.txt` file located in the `mapr` user's directory on the cluster, and store the results in the file `wordcount.txt`.

Procedure

1. Download the ZIP file that contains [constitution.txt](#) and then extract the `constitution.txt` file.
2. Load the file onto the cluster and place it in the directory `/user/mapr/in`.
3. In the terminal, type the command `pig` to start the Pig shell.
4. At the `grunt>` prompt, type the following lines (press ENTER after each): After you type the last line, Pig starts a MapReduce application to count the words in the file `constitution.txt`.

```
A = LOAD '/user/mapr/in' USING TextLoader() AS (words:chararray);
```

```
B = FOREACH A GENERATE FLATTEN(TOKENIZE(*));
```

```
C = GROUP B BY $0;
```

```
D = FOREACH C GENERATE group, COUNT(B);
```

```
STORE D INTO '/user/mapr/wordcount';
```

5. When the MapReduce application is complete, type `quit` to exit the Pig shell and take a look at the contents of the directory `/myvolume/wordcount` to see the results.

Use ORC Storage with Pig

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

This section presents simple examples for using Hive ORC storage. Use the `grunt` shell in Pig to execute the commands. For more details, see the [Pig documentation](#).

ORC is typically used to read (load) and write (store) data as follows:

```
<VAR_NAME> = load '/path/to/orc/formatted/file' using OrcStorage();
store <VAR_NAME> into '/path/to/output/orc/file' using OrcStorage('');
```

Example: Create an ORC file in the file system by storing the data in a Hive table and uploading it to Pig

About this task

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

You can create an ORC format file in the file system by using Hive to load a text file into a table with ORC storage. Then, you can upload the resulting ORC format file to Pig.

Procedure

1. Create a sample test data file:

```
cd /home/mapr
nano test_pig.data
chown mapr:mapr test_pig.data
```

2. Add data to the file.

```
John,Smith
Brian,May
Rodger,Taylor
John,Deacon
Max,Plank
Freddie,Mercury
Albert,Einstein
Fedor,Dostoevsky
Lev,Tolstoy
Niccolo,Paganini
```

NOTE: Do not include any extra lines at the end of the file.

3. Upload the test data to a Hive table:

```
sudo -u mapr hive
hive> create table test_pig(first_name string, last_name string) ROW
FORMAT DELIMITED FIELDS TERMINATED BY ',';
hive> load data local inpath '/home/mapr/test_pig.data' overwrite into
table test_pig;
```

4. Create a Hive table with ORC storage:

```
hive> create table test_pig_orc(first_name string, last_name string)
stored as orc tblproperties ("orc.compress"="NONE");
hive> insert overwrite table test_pig_orc select * from test_pig;
hive> select * from test_pig_orc;
```

5. Check that the ORC file was created:

```
hadoop fs -ls /user/hive/warehouse/test_pig_orc
```

6. Upload the ORC file to Pig:

```
sudo -u mapr pig
grunt> B = load '/user/hive/warehouse/test_pig_orc/000000_0'
using OrcStorage();
grunt> dump B;
```

Example: Upload a text file to the file system and use Pig to save it as an ORC file

Procedure

1. Upload the file to the file system:

```
cd /home/mapr
sudo -u mapr hadoop fs -put ./test_pig.data /test_pig.data
sudo -u mapr hadoop fs -mkdir /output
```

2. Start Pig and save the text file in ORC format:

```
sudo -u mapr pig
grunt> A = LOAD '/test_pig.data' using PigStorage(',') AS
(first_name:chararray, last_name:chararray);
grunt> store A into '/output/A' using OrcStorage('');
```

3. Verify that the ORC file was created:

```
hadoop fs -ls /output/A/
```

Integrate Pig

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

The following topics provide information about how to integrate Pig with other ecosystem components. You can also refer to the documentation available on the [Apache Pig](#) website.

Integrate Pig and HBase

This document shows an example of a Pig and HBase integration. The goal of integration is to upload data from the file system to Pig and then move the data to an HBase table.

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Configuring Pig and HBase

No additional configuration is needed to integrate HBase and Pig.

Pig and HBase Integration Example

1. Create sample data, and upload the data to the file system:
 - a. Create a sample data file:

```
vim input.csv
```

b. Add data to the file:

```
1,aaa,bbb
2,ccc,ddd
3,rrr,fff
4,ttt,yyy
```

c. Upload the data to the file system:

```
hadoop fs -put input.csv /user/mapr/input.csv
```

2. Create a sample table in HBase:**a. Start the HBase shell:**

```
hbase shell
```

b. Create a table:

```
hbase(main):012:0> create 'sample_names', 'info'
```

3. Load the data to Pig, and store the data in HBase:**a. Start the Pig shell:**

```
pig
```

b. Load the data to Pig:

```
raw_data = LOAD '/user/mapr/input.csv' USING PigStorage(',') AS
(listing_id: chararray, fname: chararray, lname: chararray);
```

c. Store the data in HBase:

```
STORE raw_data INTO 'sample_names' USING
org.apache.pig.backend.hadoop.hbase.HBaseStorage ('info:fname
info:lname');
```

4. Verify the data in HBase:**a. Start the HBase shell:**

```
hbase shell
```

b. Query the data:

```
hbase(main):017:0* scan 'sample_names'
```

The result is:

```
ROW
COLUMN+CELL
```

```

1 column=info:fname, timestamp=1574946889082, value=aaa
1 column=info:lname, timestamp=1574946889082, value=bbb
2 column=info:fname, timestamp=1574946889091, value=ccc
2 column=info:lname, timestamp=1574946889091, value=ddd
3 column=info:fname, timestamp=1574946889091, value=rrr
3 column=info:lname, timestamp=1574946889091, value=fff
4 column=info:fname, timestamp=1574946889091, value=ttt
4 column=info:lname, timestamp=1574946889091, value=yyy

```

Integrate Pig and HPE Ezmeral Data Fabric Database

About this task

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

To configure Pig to work with HPE Ezmeral Data Fabric Database tables, perform the following steps:

Procedure

1. On the client node where Pig is installed, add the following string to `/opt/mapr/conf/env.sh`:

```
export PIG_CLASSPATH=$PIG_CLASSPATH:/location-to-hbase-jar
```

2. If the client node where Pig is installed also has the `mapr-hbase` package installed, add the location of the `hbase-<version>.jar` file to the `PIG_CLASSPATH` variable from the previous step:

```
export PIG_CLASSPATH="$PIG_CLASSPATH:/opt/mapr/hbase/hbase-<version>/
hbase-<version>.jar"
```

3. If the client node where Pig is installed does not have the `mapr-hbase` package installed, copy the HBase JAR from a node that does have HBase installed to a location on the Pig client node. Add the HBase JAR's location to the definition from previous steps:

```
export PIG_CLASSPATH=$PIG_CLASSPATH:/opt/mapr/lib/hbase-<version>.jar
```

4. Add the HBase JAR to the Hadoop classpath:

```
export HADOOP_CLASSPATH="/opt/mapr/hbase/hbase-<version>/
hbase-<version>-mapr.jar:$HADOOP_CLASSPATH"
```

5. Launch a Pig job and verify that Pig can access HBase tables by using the HBase table name directly. Do not use the `hbase://` prefix.

Pig 0.16.0 API

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

This section contains the following topics:

New API in Pig 0.16.0

! **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Fig 0.16.0 includes the following new classes and interfaces.

New Classes

Class	Description
org.apache.pig.piggybank.evaluation.string.REPLACE_MULTI	<p>REPLACE_MULTI implements eval function to replace all occurrences of search keys with replacement values. Replacement values are specified in Map. For example:</p> <pre>input_data = LOAD 'input_data' as (name); -- name = 'Hello World!' replaced_name = FOREACH input_data \ GENERATE REPLACE_MULTI (name, ['#_','!#','e#a','o#oo']); -- replaced_name = Halloo_Woorld</pre> <p>The first argument is the source string on which REPLACE_MULTI operation is performed. The second argument is a map having search key with replacement value pairs.</p>
org.apache.pig.piggybank.storage.apachelog.LogFormat Loader	<p>This is a pig loader that can load Apache HTTPD access logs written in (almost) any Apache HTTPD LogFormat.</p> <p><i>Basic usage:</i> Feed the loader your (custom) logformat specification and it will show the fields that can be extracted from this logformat.</p>
org.apache.pig.CounterBasedErrorHandler	<p>Handles errors thrown by the <code>StoreFuncInterface.putNext()</code>.</p>
org.apache.pig.backend.hadoop.HKerberos	<p>Support for logging in using a Kerberos keytab file.</p> <p>Kerberos is an authentication system that uses tickets with limited validity time. Running a Pig script on a Kerberos secured Hadoop cluster limits the running time to at most the remaining validity time of the Kerberos tickets. When doing really complex analytics, this may become a problem as the job may need to run for a longer time than these ticket times allow. A Kerberos keytab file is a Kerberos specific form of the password of a user. It is possible to enable a Hadoop job to request new tickets when they expire by creating a keytab file and making it part of the job that is running in the cluster. This will extend the maximum job duration beyond the maximum renew time of the Kerberos tickets.</p>
org.apache.pig.backend.hadoop.executionengine.mapReduceLayer.PigWritableComparators	<p>Byte only raw comparators for faster comparison for non-orderby jobs. This does not reuse <code>JobControlCompiler.Pig<DataType>WritableComparator</code>, which extends <code>PigWritableComparator</code>. The <code>PigNullablePartitionWritable.compare</code> is not that efficient in cases where tuple is iterated for null checking instead of taking advantage of <code>TupleRawComparator.hasComparedTupleNull()</code>. This also skips multi-query index checking.</p>

Class	Description
org.apache.pig.backend.hadoop.executionengine.physicalLayer.relationalOperators.StoreFuncDecorator	This class is used to decorate the <code>StoreFunc#putNext(Tuple)</code> . It handles errors by calling <code>OutputErrorHandler#handle(String, long, Throwable)</code> if the <code>StoreFunc</code> implements <code>ErrorHandling</code> .
org.apache.pig.backend.hadoop.executionengine.tez.runtime.PigInputFormatTez	Extends <code>org.apache.hadoop.mapreduce.InputFormat</code> and implements Pig and Tez specific functions.
org.apache.pig.backend.hadoop.executionengine.tez.util.TezUDFContextSeparator	Extends a visitor for the <code>TezOperPlan</code> class and serializes all (<code>LoadFunc</code> , <code>StoreFunc</code> , <code>UserFunc</code>).
org.apache.pig.impl.io.compress.BZip2CodecWithExtensionBZ	For historical reasons, Pig supports <code>.bz</code> and <code>.bz2</code> for <code>bzip2</code> extension. This class returns the additional <code>bzip2</code> file extension, <code>.bz</code> , as a string.
org.apache.pig.impl.util.UDFContextSeparator	<code>TezUDFContextSeparator</code> extends <code>PhyPlanVisitor</code> , which is the visitor class for the Physical Plan. To use this, create the visitor with the plan to be visited. Call the <code>visit()</code> method to traverse the plan in a depth first fashion. This class also visits the nested plans inside the operators. Extend this class to modify the nature of each visit and to maintain any relevant state information between the visits to two different operators.
org.apache.pig.parser.RegisterResolver	Resolves a JAR with a scripting language or namespace.
org.apache.pig.tools.DownloadResolver	Makes a list of URIs of the downloaded JARs.

New Interfaces

Interface	Description
org.apache.pig.ErrorHandler	The interface that handles errors thrown by <code>StoreFuncInterface.putNext(Tuple)</code> .
org.apache.pig.ErrorHandling	The interface to enable handling of errors during <code>StoreFunc#putNext(Tuple)</code> .

Deprecated API in Pig 0.16.0

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

The following interfaces, classes, fields, and methods have been deprecated in Pig 0.16.0.

Deprecated Interfaces

Instead of this deprecated interface...	Use...
org.apache.pig.PigToStream	PigStreamingBase
org.apache.pig.StreamToPig	PigStreamingBase

Deprecated Classes

Instead of this deprecated class...	Use...
org.apache.pig.piggybank.evaluation.math.ABS	ABS
org.apache.pig.piggybank.evaluation.math.ACOS	ACOS
org.apache.pig.builtin.ARITY	SIZE
org.apache.pig.piggybank.evaluation.math.ASIN	ASIN
org.apache.pig.piggybank.evaluation.math.ATAN	ATAN
org.apache.pig.piggybank.evaluation.math.Base	Base
org.apache.pig.piggybank.evaluation.math.CBRT	CBRT
org.apache.pig.piggybank.evaluation.math.CEIL	CEIL
org.apache.pig.ComparisonFunc	N/A
org.apache.pig.piggybank.evaluation.stats.COR	COR
org.apache.pig.piggybank.evaluation.math.COS	COS
org.apache.pig.piggybank.evaluation.math.COSH	COSH
org.apache.pig.piggybank.evaluation.stats.COV	COV
org.apache.pig.data.DefaultTupleFactory	TupleFactory
org.apache.pig.piggybank.evaluation.math.DoubleAbs	DoubleAbs
org.apache.pig.piggybank.evaluation.math.DoubleBase	DoubleBase
org.apache.pig.piggybank.evaluation.math.DoubleRound	DoubleRound
org.apache.pig.piggybank.evaluation.math.EXP	EXP
org.apache.pig.piggybank.evaluation.math.FloatAbs	FloatAbs
org.apache.pig.piggybank.evaluation.math.FloatRound	FloatRound
org.apache.pig.piggybank.evaluation.math.FLOOR	FLOOR
org.apache.pig.piggybank.evaluation.string.INDEXOF	INDEXOF
org.apache.pig.piggybank.evaluation.math.IntAbs	IntAbs

org.apache.pig.tools.pigstats.ScriptState.start(String, PigContext)	ScriptState.start(ScriptState)

Apache Spark

Apache Spark is an open-source processing engine that you can use to process Hadoop data. The following diagram shows the components involved in running Spark jobs. See [Spark Cluster Mode Overview](#) for additional component details.

HPE Ezmeral Data Fabric supports the following types of cluster managers:

- Spark's standalone cluster manager
- YARN

The configuration and operational steps for Spark differ based on the Spark mode you choose to install. The steps to integrate Spark with other components are the same when using either Standalone or YARN cluster mode, except where otherwise noted.

This section provides documentation about configuring and using Spark with HPE Ezmeral Data Fabric, but it does not duplicate the [Apache Spark](#) documentation.

You can also refer to additional documentation available on the [Apache Spark Product Page](#).

Getting Started with Spark Interactive Shell

After you have a basic understanding of Apache Spark and have it installed and running on your cluster, you can use it to load datasets, apply schemas, and query data from the Spark interactive shell.

Reading Data from file system

1. Copy sample data into file system:
 - For this example, the dataset constitutes a CSV file of a list of auctions.

- Download the file from GitHub: <https://github.com/mapr-demos/getting-started-spark-on-mapr/tree/master/data>.

- Copy the file into your cluster, in the `/apps/` directory, using the `cp/scp` or `hadoop put` command:

```
scp ./data/auctiondata.csv mapr@[mapr-cluster-node]:/mapr/[cluster-name]/apps/
or
$ hadoop fs -put ./data/auctiondata.csv /apps
```

- This dataset is from eBay online auctions. The dataset contains the following fields:

```
auctionid - Unique identifier of an auction.
bid - Proxy bid placed by a bidder.
bidtime - Time (in days) that the bid was placed from the start of the auction.
bidder - eBay username of the bidder.
bidderrate - eBay feedback rating of the bidder.
openbid - Opening bid set by the seller.
price - Closing price that the item sold for (equivalent to the second highest bid + an increment).
item - Type of item.
```

The table below shows the fields with some sample data:

auctionid	bid	bidtime	bidder	bidderrate	openbid	price	item	daystolive
8213034705	95	2.927373	jake7870	0	95	117.5	xbox	3

2. Start the Spark interactive shell:

- `$SPARK_HOME` represents the home of your Spark installation in MapR, for example: `/opt/mapr/spark/spark-2.2.1/`.

```
$ $SPARK_HOME/bin/spark-shell --master local[2]
```

3. Once the Spark shell is ready, load the dataset:

```
scala> val auctionData = spark.read.textFile("/apps/auctiondata.csv")
```

4. Display the first entry:

```
scala> auctionData.first()
```

5. Count the number of entries:

```
scala> auctionData.count()
```

6. Use other Spark actions:

```
// Displays first 20 lines
scala> auctionData.show()

// Displays first 3 lines - change value to see more/less
scala> auctionData.take(3)
```

7. Transform the dataset into a new one that contains only `xbox` lines, and count them:

```
scala> val auctionWithXbox = auctionData.filter(line =>
line.contains("xbox"))
scala> auctionWithXbox.count()
```

- This could also be done in a single line by chaining transformations and actions:

```
scala> auctionData.filter(line => line.contains("xbox")).count()
```

8. Use Spark Dataframes:

```
scala> val auctionDataFrame =
spark.read.format("csv").option("inferSchema",
true).load("/apps/
auctiondata.csv").toDF("auctionid", "bid", "bidtime", "bidder", "bidderrate",
"openbid", "price", "item", "daystolive")
```

9. Use a filter transformation on the Dataframe:

```
scala> auctionDataFrame.filter($"price" < 30).show()
```

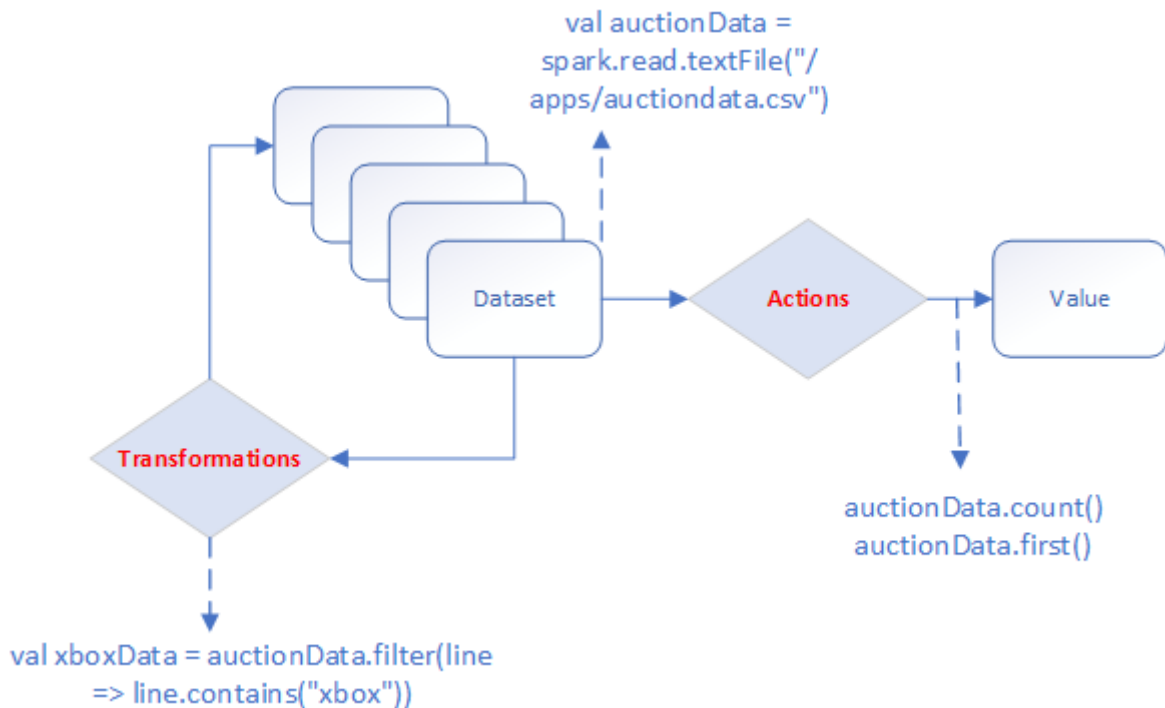

Figure 35: Schematic representation of performing transformations and actions on a dataset

Writing Data from file system

Using the same dataset, save all `xbox` items as a file in file system:

- You can use the `filter($"item" === "xbox")` filter and `write.json` or other options to save the result of the action to file system.

```
scala> auctionDataFrame.filter($"item" === "xbox").write.json("/apps/
results/json/xbox")
```

This command creates the `/apps/results/json/xbox` directory in which you will see the JSON file(s) created. You can use the same command to create Parquet or any other file format:

```
scala> auctionDataFrame.filter($"item" === "xbox").write.parquet("/apps/
results/parquet/xbox")
```

Writing Data to HPE Ezmeral Data Fabric Database JSON

The first step when you are working with HPE Ezmeral Data Fabric Database JSON is to define a document `_id` that uniquely identifies the document.

Add a new `_id` field in the csv file and generate UUIDs to add to this field.

To load the Dataframe into the MapR-DB JSON:

```
dataframe.saveToMapRDB("tableName", createTable = true, bulkInsert = false,
idFieldPath = "_id")
```

The following commands will create a table and insert the data into: `/apps/auction_json_table`.

```
scala> import spark.implicits._
scala> import java.util.UUID
scala> import org.apache.spark.sql.SparkSession
scala> import org.apache.spark.sql.types._
scala> import org.apache.spark.sql.SaveMode
scala> import com.mapr.db.spark.sql._ // import the MapR-DB OJAI Connector
scala> val generateUUID = udf(() => UUID.randomUUID().toString) // create
UDF to generate UUID
scala> // showing that you can create your own schema
val customSchema =
  StructType(
    Array(
      StructField("actionid", StringType, true),
      StructField("bid", DoubleType, true),
      StructField("bidtime", DoubleType, true),
      StructField("bidder", StringType, true),
      StructField("bidderrate", IntegerType, true),
      StructField("openbid", DoubleType, true),
      StructField("price", DoubleType, true),
      StructField("item", StringType, true),
      StructField("daystolive", IntegerType, true)
    )
  )
```

You can now query the table using the HPE Ezmeral Data Fabric Database shell. Open a terminal on your cluster and run the following command:

```
$ mapr dbshell
maprdb mapr:> find /apps/auction_json_table --limit 10
```

Reading Data from HPE Ezmeral Data Fabric Database JSON

Now that you have the data in HPE Ezmeral Data Fabric Database JSON, you can create and query a Spark Dataframe using the following commands:

```
scala> import com.mapr.db.spark.sql._
scala> import org.apache.spark.sql.Session
scala> val dataFromMapR = spark.loadFromMapRDB("/apps/auction_json_table")
scala> dataFromMapR.printSchema
scala> dataFromMapR.count

scala> dataFromMapR.filter($"price" < 30).show() // use a filter
```

- [Spark configure.sh](#) on page 4519
- [HPE Ezmeral Spark blog](#)

Apache Spark Feature Support

HPE Ezmeral Data Fabric supports most Apache Spark features. However, there are some exceptions.

GPU Aware Scheduling Support on Spark

HPE Ezmeral Data Fabric does not support GPU aware scheduling feature on Spark 3.1.2 and Spark 3.2.0. You must have Hadoop 3.x to support the GPU aware scheduling feature on Spark 3. However, EEP 8.x.x supports Hadoop 2.7.6 and thus YARN will not be able to allocate the GPU resources for the Spark Applications.

Delta Lake Support on Spark

Starting from EEP 8.x.x, Apache Spark 3 provides Delta Lake support on HPE Ezmeral Data Fabric.

Delta Lake is an open-source storage layer that supports ACID (Atomicity, Consistency, Isolation, and Durability) transactions to provide reliability, consistency, and scalability to Apache Spark applications. Delta Lake runs on the top of the existing storage and is compatible with Apache Spark APIs. For more details, see [Delta Lake documentation](#).

You can use any Apache Spark APIs to read and write data with Delta Lake. Delta Lake stores the data in Parquet format as versioned Parquet files. Delta Lake has a well-defined open protocol called [Delta Transaction Protocol](#) that provides ACID transactions to Apache Spark applications.

To enable the Delta Lake:

1. Download the Delta Lake library from [Maven repository](#).

2. Add the Delta Lake library and set the following configuration options. For example:

```
/opt/mapr/spark/spark-3.1.2/bin/
spark-shell --jars ~/
delta-core_2.1.2-1.0.0.jar
--conf "spark.sql.extensions"=
io.delta.sql.DeltaSparkSessionExten
sion
--conf
"spark.sql.catalog.spark_catalog"=
org.apache.spark.sql.delta.catalog.
DeltaCatalog
```

Delta Lake stores the commits of every successful transaction (Spark job) as a DeltaLog or a Delta Lake transaction log.

For example: You can view these commit logs on MinIO Browser by navigating to `/<table_name>/_delta_Log/`.

Commits in the transaction log:

```
/<table_name>/_delta_log/
00000000000000000000000000000000.json
/<table_name>/_delta_log/
00000000000000000000000000000001.json
/<table_name>/_delta_log/
00000000000000000000000000000003.json
```

Delta lake uses optimistic concurrency control to provide ACID transactions between writes operation. See [Concurrency Control](#).

See [Setup Apache Spark with Delta Lake](#) and [Advanced Dependency Management](#) to start using Delta Lake.

Spark SQL and Apache Derby Support on Spark

If you are using Spark SQL with Derby database without Hive or Hive Metastore installation, you will see the following exception:

```
java.lang.RuntimeException: Unable to
instantiate
org.apache.hadoop.hive.ql.metadata.Ses
sionHiveMetaStoreClient
```

Add the `hive-service-2.3.*.jar` and `log4j2` jars to `/opt/mapr/spark/spark-3.x.x/jars` location to use Spark SQL with Derby Database without Hive or Hive Metastore installation.

The `log4j2` jars are located at `/opt/mapr/lib/log4j2/log4j-*.jar` location.

Spark 3.1.2 and Spark 3.2.0 does not support `log4j1.2` logging on HPE Ezmeral Data Fabric.

Spark Thrift JDBC/ODBC Server Support

Running the Spark Thrift JDBC/ODBC Server on a secure cluster is supported only on Spark 2.1.0 or later.

You can run the Spark Thrift JDBC/ODBC Server to enable connections to Hive 1.2.1 using Beeline;

Spark SQL and Hive Support for Spark 2.1.0

however, you can connect only to Hive versions supported by your Spark version.

Spark 2.1.0 is able to connect to Hive 2.1 Metastore; however, only features of Hive 1.2 are supported.

Spark SQL and Hive Support for Spark 2.0.1

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#).

The following Hive functions are not supported in Spark SQL:

- Tables with buckets
- UNION type
- Unique join
- Column statistics collecting
- Output formats: File format (for CLI), Hadoop Archive
- Block-level bitmap indexes and virtual columns
- Automatic determination of the number of reducers for JOIN and GROUP BY
- Metadata-only query
- Skew data flag
- STREAMTABLE hint in JOIN
- Merging of multiple small files for query results

Spark SQL and Hive Support for Spark 1.6.1

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#). The following Spark SQL operations support the following Hive table formats:

	Hive 1.2 Table Format				
Spark SQL Operations	AVRO	ORC	Parquet	RC	default
create	Yes	Yes	Yes	Yes	Yes
drop	Yes	Yes	Yes	Yes	Yes
insert into	Yes	Yes	Yes	Yes	Yes
insert overwrite	Yes	Yes	Yes	Yes	Yes
select	Yes	Yes	Yes	Yes	Yes
load data	Yes	Yes	Yes	Yes	Yes

Spark Standalone

This section includes topics about configuring and using Spark in Standalone mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#).

For additional documentation, see the [Apache Spark](#) website.

Installing Spark Standalone

This topic describes how to use package managers to download and install Spark Standalone from the EEP repository.

Prerequisites

To set up the EEP repository, see [Step 11: Install Ecosystem Components Manually](#) on page 183.

About this task

Spark is distributed as four separate packages:

Package	Description
mapr-spark	Install this package on any node where you want to install Spark. This package is dependent on the <code>mapr-client</code> , <code>mapr-hadoop-client</code> , <code>mapr-hadoop-util</code> , and <code>mapr-librdkafka</code> packages.
mapr-spark-master	Install this package on Spark master nodes. Spark master nodes must be able to communicate with Spark worker nodes over SSH without using passwords. This package is dependent on the <code>mapr-spark</code> and the <code>mapr-core</code> packages.
mapr-spark-historyserver	Install this optional package on Spark History Server nodes. This package is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.
mapr-spark-thriftserver	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.

Run the following commands as `root` or using `sudo`.

Procedure

1. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory.

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

NOTE: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically.

2. Install Spark using the appropriate commands for your operating system:

On CentOS 8.x / Red Hat 8.x

```
dnf install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

On Ubuntu

```
apt-get install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

On SLES

```
zypper install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

NOTE: The `mapr-spark-historyserver`, `mapr-spark-master`, and `mapr-spark-thriftserver` packages are optional.

Spark is installed into the `/opt/mapr/spark` directory.

3. For Spark 2.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

For Spark 3.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/workers.template` into `/opt/mapr/spark/spark-<version>/conf/workers`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

For example:

```
localhost
worker-node-1
worker-node-2
```

4. Set up [passwordless ssh](#) for the `mapr` user such that the Spark master node has access to all secondary nodes defined in the `conf/slaves` file for Spark 2.x and `conf/workers` file for Spark 3.x.**5. As the `mapr` user, start the worker nodes by running the following command in the master node. Since the Master daemon is managed by the Warden daemon, do not use the `start-all.sh` or `stop-all.sh` command.**

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

6. If you want to integrate Spark with HPE Ezmeral Data Fabric Streams, install the Streams Client on each Spark node:

- On Ubuntu:

```
apt-get install mapr-kafka
```

- On RedHat/CentOS:

```
yum install mapr-kafka
```

7. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the HPE Ezmeral Data Fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).
8. After installing Spark Standalone but before running your Spark jobs, follow the steps outlined at [Configuring Spark Standalone](#) on page 4510.

Configuring Spark Standalone

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run `configure.sh -R` as the final step in the configuration process.

Configure High Availability for SparkMaster

You configure high availability for the Spark Primary instance so that the instance does not become the single point of failure.

By using ZooKeeper to provide leader election and some state storage, you can launch multiple primary nodes in your cluster that are connected to the same ZooKeeper instance. Zookeeper elects one primary node to be the “leader,” and the others remain in standby mode. If the leader goes down, Zookeeper elects another primary node, recovers the old primary node's state, and resumes scheduling.

1. Set `SPARK_DAEMON_JAVA_OPTS` in `spark-env.sh` with the appropriate ZooKeeper information for the cluster.

```
export SPARK_DAEMON_JAVA_OPTS="-Dspark.deploy.recoveryMode=ZOOKEEPER
-Dspark.deploy.zookeeper.url=<zookeeper1:5181,zookeeper2:5181,...>
-Djava.security.auth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.sasl.client=false
```

2. Restart the Spark Primary instance and Spark History Server services:

- For Spark 2.0.1 and later:

```
maprcli node services -nodes <node-ip> -name spark-master -action
restart
```

- For Spark 1.6.1:

```
maprcli node services -nodes <node-ip> -name spark-master -action
restart
maprcli node services -nodes <node-ip> -name
spark-historyserver -action restart
```

3. On the primary node, restart the Spark Secondary instances as the `mapr` user.

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-slaves.sh
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-workers.sh
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

Configure Scratch Directory for Spark Standalone

By default, Spark uses the `/tmp` directory as scratch space. Map output files and RDDs are stored in the scratch directory. To use a different directory, or a comma-separated list of multiple directories, set

SPARK_LOCAL_DIRS to the path to the new directory by adding the following line to the `$SPARK_HOME/conf/spark-env.sh` file:

```
export SPARK_LOCAL_DIRS=$SPARK_HOME/<path to scratch directory>
```

Make this change before starting the Spark services.

Community Edition (Without NFS Support)

Reserve space on your local disk to use as the scratch directory for Spark.

Enterprise Edition and Enterprise Database Edition (With NFS Support)

Create a local volume on each node with the `maprcli volume create` command, or from the Control System. Mount that local volume with NFS to a directory. Set that directory as the scratch directory for Spark.

NOTE: Due to <https://issues.apache.org/jira/browse/SPARK-6313>, make sure to set `spark.files.useFetchCache=false` in your `spark-defaults.conf` file.

Using Spark Standalone

For a simple test of your Spark installation, run the following command:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master spark://<Spark Master node hostname>:7077 SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/spark-<version>/bin/run-example org.apache.spark.examples.SparkPi 10
```

For more information about running Spark applications, see the [Apache Spark Documentation](#).

Run the Spark Shell in Standalone Mode

Procedure

- To run the Spark shell, use the following command:

- On Spark 2.0.1 and later:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell --master spark://<Spark Master node hostname>:7077
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/spark-<version>/bin/spark-shell
```

Security with Spark Standalone

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the MapR installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure

clusters. See [Spark configure.sh](#) on page 4519 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

Spark on YARN

This section contains topics about installing, configuring and using Spark on YARN.

 **IMPORTANT:** Spark 2.0.1 (and later) YARN mode is supported only on clusters in MRv2 (YARN) mode. It is not supported on clusters in MRv1 (classic) mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#) on page 4594

For additional documentation, see the [Apache Spark](#) documentation.

Installing Spark on YARN

This topic describes how to use package managers to download and install Spark on YARN from the EEP repository.

Prerequisites

To set up the EEP repository, see [Step 11: Install Ecosystem Components Manually](#) on page 183.

About this task

Spark is distributed as three separate packages:

Package	Description
<code>mapr-spark</code>	Install this package on any node where you want to install Spark. This package is dependent on the <code>mapr-client</code> , <code>mapr-hadoop-client</code> , <code>mapr-hadoop-util</code> , and <code>mapr-librdkafka</code> packages.
<code>mapr-spark-historyserver</code>	Install this optional package on Spark History Server nodes. This package is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.
<code>mapr-spark-thriftserver</code>	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.

To install Spark on YARN (Hadoop 2), execute the following commands as `root` or using `sudo`:

Procedure

1. Verify that JDK 11 or later is installed on the node where you want to install Spark.
2. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory:

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

NOTE: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically when using the Installer. However, you must manually create this directory when performing a manual installation.

3. Install the packages:

On Ubuntu

```
apt-get install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

On CentOS 8.x / Red Hat 8.x

```
dnf install mapr-spark
mapr-spark-historyserver
mapr-spark-thriftserver
```

On SLES

```
zypper install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

NOTE: The `mapr-spark-historyserver` and `mapr-spark-thriftserver` packages are optional.

- If you want to integrate Spark with HPE Ezmeral Data Fabric Streams, install the Streams Client on each Spark node:

- On Ubuntu:**

```
apt-get install mapr-kafka
```

- On CentOS / Red Hat:**

```
yum install mapr-kafka
```

- If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the data-fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).
- For repository-specific information, see [Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4631
- After installing Spark on YARN but before running your Spark jobs, follow the steps outlined at [Configuring Spark on YARN](#) on page 4513.

Configuring Spark on YARN

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run [configure.sh -R](#) as the final step in the configuration process.

Configure Data Fabric Client Node to Run Spark Applications

When Spark runs on YARN, Data Fabric client nodes require the `hadoop-yarn-server-web-proxy` JAR file to run Spark applications. On Windows, the client node also requires an update to the `SPARK_DIST_CLASSPATH`. A Data Fabric client node (a node with the `mapr-client` package, but without `mapr-core` packages) is also known as an edge node.

The `mapr-client` package does not include the JAR file required to run Spark applications. Therefore, you must copy the following JAR file from a Data Fabric cluster node to the same location on the Data Fabric client node where you want to run the Spark application:

```
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/
hadoop-yarn-server-web-proxy-<version>.jar
```

For example, here is a JAR file path for Hadoop 3.3.5:

```
/opt/mapr/hadoop/hadoop-3.3.5/share/hadoop/yarn/
hadoop-yarn-server-web-proxy-3.3.5.100-ee-920.jar
```

Configure Spark JAR Location

About this task

By default, Spark on YARN uses Spark JAR files that are installed locally. The Spark JAR files can also be added to a world-readable location on file system. When you add the JAR files to a world-readable location, YARN can cache them on nodes to avoid distributing them each time an application runs. Complete the following steps to add the Spark JAR files to a world-readable location on file system:

Procedure

1. Create a zip archive containing all the JARs from the `SPARK_HOME/jars` directory. For example:

```
cd /opt/mapr/spark/spark-<version>/jars/
zip /opt/mapr/spark/spark-<version>/spark-jars.zip ./*
```

2. Copy the zip file from the local filesystem to a world-readable location on file system. You can upload it to the home of the current user:

```
hadoop fs -put /opt/mapr/spark/spark-<version>/spark-jars.zip
```

For example:

```
hadoop fs -put /opt/mapr/spark/spark-3.2.0/spark-jars.zip /user/mapr/
```

3. Set the `spark.yarn.archive` property in the `spark-defaults.conf` file located in `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` to point to the world-readable location where you added the zip file. Apply this setting on the node where you will be submitting your Spark jobs.

```
spark.yarn.archive maprfs:///<path to zip>
```

For example:

```
spark.yarn.archive maprfs:///user/mapr/spark-jars.zip
```

Configure Spark with the NodeManager Local Directory Set to file system

About this task

This procedure configures Spark to use the mounted NFS directory instead of the `/tmp` directory on the local file system. Note that spill to disk should be configured to spill to the file system node local storage only if local disks are unavailable or space is limited on those disks.

Procedure

1. Install the `mapr-loopbacknfs` and `nfs-utils` packages if they are not already installed. For reference, see [Installing the mapr-loopbacknfs Package](#) on page 384 and [Setting Up MapR NFS](#).
2. Start the `mapr-loopbacknfs` service by following the steps at [Managing the mapr-loopbacknfs Service](#) on page 1541.

3. To configure Spark Shuffle on NFS, complete these steps **on all nodes**:

- a) Create a local volume for Spark Shuffle:

```
sudo -u mapr maprcli volume
create -name mapr.${hostname -f}.local.spark -path /var/mapr/local/${
hostname -f}/spark -replication 1 -localvolumehost ${hostname -f}
```

- b) Point the NodeManager local directory to the Spark Shuffle volume mounted through NFS by setting the following property in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml` file on the NodeManager nodes:

```
<property>
  <name>yarn.nodemanager.local-dirs</name>
  <value>/mapr/my.cluster.com/var/mapr/local/${mapr.host}/spark</
value>
</property>
```

- c) (Optional) Configure how many times the NodeManager can attempt to delete application-related directories from a volume when Spark is configured to use the mounted NFS directory instead of the `/tmp` directory on the local file system. Increasing the value (default is 2) of this property can prevent application cache data from accumulating in the volume. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See [Applying a Patch](#).

```
<property>
  <name>yarn.nodemanager.max-retry-file-delete</name>
  <value>2</value>
</property>
```

- d) Restart the NodeManager service and the Resource Manager service on the main node to pick up the `yarn-site.xml` changes:

```
maprcli node services -name nodemanager -action restart -nodes <node
1> <node 2> <node 3>
maprcli node services -name resourcemanager -action restart -nodes
<node 1> <node 2> <node 3>
```

Using Spark on YARN

This section includes information about using Spark on YARN in a data-fabric cluster.

For a simple test of your Spark installation, run the following command as the `mapr` user:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master
yarn --deploy-mode client SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=yarn-client /opt/mapr/spark/spark-<version>/bin/run-example
org.apache.spark.examples.SparkPi 10
```

NOTE: These commands will fail if it is run as the root user.

For more information about running Spark applications, see the [Apache Spark documentation](#).

Deployment Modes

Spark is preconfigured for YARN and does not require any additional configuration to run.

Two deployment modes can be used to launch Spark applications on YARN:

- In `cluster` mode, jobs are managed by the YARN cluster. The Spark driver runs inside an Application Master (AM) process that is managed by YARN. This means that the client can go away after initiating the application.
- In `client` mode, the Spark driver runs in the client process, and the Application Master is used only to request resources from YARN.

MapR recommends using `cluster` deployment mode instead of `client` mode. If the Spark client that runs the job exits after submitting the job, there is no impact on job completion.

Note: In `cluster` deployment mode, the local directories used by the Spark executors and the Spark driver are the local directories that are configured for YARN (`yarn.nodemanager.local-dirs`).

NOTE: `SPARK_LOCAL_DIRS` is ignored when you run Spark on YARN.

Run Spark from the Spark Shell

About this task

In `yarn-client` mode, complete the following steps to run Spark from the Spark shell:

Procedure

1. Navigate to the Spark-on-YARN installation directory, and insert your Spark version into the command.

```
cd /opt/mapr/spark/spark-<version>/
```

2. Issue the following command to run Spark from the Spark shell:

- On Spark 2.0.1 and later:

```
./bin/spark-shell --master yarn --deploy-mode client
```

- On Spark 1.6.1:

```
MASTER=yarn-client ./bin/spark-shell
```

NOTE: You must use `yarn-client` mode to run Spark from the Spark shell. The `yarn-cluster` mode is not supported.

Security with Spark on YARN

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the MapR installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See [Spark configure.sh](#) on page 4519 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

Configure Authentication for Spark on YARN

When authentication is enabled, authentication keys are randomly generated for each job.

Prerequisites

NOTE: Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#), as the final step in the configuration process, enables these settings.

About this task

Complete the following step to manually configure authentication on a non-secure cluster or in versions earlier than EEP 4.0:

Procedure

1. Configure the following property in the `spark-defaults.conf` file on each Spark node:

```
spark.authenticate true
```

The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`

2. If you have configured an external shuffle service, you must also add the following property to [`yarn-site.xml`](#) on page 2860 on each Spark node:

```
<property>
  <name>spark.authenticate</name>
  <value>true</value>
</property>
```

Configure SSL Encryption for Spark on YARN

Prerequisites

Starting in EEP 8.0.0, if you are Non-Admin user starting a Spark Application, you must generate the KeyStore and KeyStore password and set it in Spark configuration files. For details, see [Security - Spark 3.1.2 Documentation](#). Otherwise, KeyStore and default KeyStore password generates automatically.

Starting in EEP 6.0.0, you can remove `spark.ssl.keyStorePassword`, `spark.ssl.trustStorePassword`, and `spark.ssl.keyPassword` from the `spark-defaults.conf` file for additional security. These passwords are stored in the `/opt/mapr/conf/ssl-client.xml` file and Spark can access passwords from this file itself.

NOTE: If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-2.3.1/conf/spark-defaults.conf` files, then the password from the `spark-defaults.conf` file is used.

About this task

Complete the following step to manually configure encryption for the Spark HTTP file and broadcast servers:

Procedure

In the `spark-defaults.conf` file on each spark node, configure the following properties. Starting in EEP 6.0.0, the configured algorithms mentioned in the following code are no longer

available for your web service to pick up. You must remove the `spark.ssl.enabledAlgorithms TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA` line to let parties negotiate the matching ciphers.

- For Spark 2.0.1 and later:

```
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
```

NOTE: Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#), as the final step in the configuration process, enables these settings.

- For Spark 1.6.1:

```
spark.ssl.akka.enabled true
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
```

Spark UI SSL is not needed when running Spark on YARN because encryption is provided by the YARN protocol. **For versions prior to EEP 4.1.0**, to enable users logged in with a normal user account (not mapr or root) to run spark jobs on the cluster, disable Spark SSL for Spark-on-YARN jobs. To disable Spark SSL, add `spark.ssl.ui.enabled false` to the `spark-defaults.conf` file on each spark node. The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`. Make sure SSL is enabled for the Spark history server.

When you manually configure encryption for Spark, set the same protocol and algorithms for each node. Otherwise, the connection between those components might fail.

Configure SASL Encryption for Spark on YARN

Prerequisites

NOTE: Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#), as the final step in the configuration process, enables these settings.

About this task

Complete the following steps to manually enable SASL encryption on a non-secure cluster or in versions earlier than EEP 4.0:

Procedure

1. Verify that authentication is enabled, or configure authentication. SASL encryption uses the same authentication keys.

For more information, see [Configure Authentication for Spark on YARN](#) on page 4517

2. Configure the following property in the `spark-defaults.conf` file on each spark node.

```
spark.authenticate.enableSaslEncryption true
```

The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`

Spark configure.sh

Starting in the EEP 4.0 release, run `configure.sh -R` to complete your Spark configuration when manually installing Spark or upgrading to a new version.

The command is the following:

```
/opt/mapr/server/configure.sh -R
```

NOTE: You do not need to run this script for new installs, if you are using the Installer in EEP 4.0 or later.

In the case of [Spark Standalone](#) on page 4507 and [Spark on YARN](#) on page 4512, this is the last step in the configuration process.

All security configuration properties are specified within the following comment block in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
#SECURITY BLOCK
...
#END OF THE SECURITY CONFIGURATION BLOCK
```

Do not remove these comments from the file, as well as any other comments within the block inserted by `configure.sh`. The script uses these comments to locate security properties.

To set ports to special values, use the `spark.driver.port` and `spark.blockManager.port` properties.

Starting in EEP 6.0.0, Spark services such as the History Server, Thrift Server, or Primary are restarted by `configure.sh` only for changes to the following Spark configuration files: `spark-defaults.conf`, `spark-env.sh`, `hive-site.xml`, or `log4j.properties`. If these files are unchanged, `configure.sh` does not restart any of the Spark services.

An update to Spark causes the `conf` directory from the previous the Spark version to be saved to the `spark-<old-version>.<old-timestamp>` directory. If your Spark version did not change during the update, then configurations from the `spark-<old-version>.<old-timestamp>` directory is automatically copied to the `spark-<version>` directory by the `configure.sh` script.

If you use `.customSecure`, at the first run, the `configure.sh` script copies the `hive-site.xml` file from Hive. For subsequent times, the `hive-site.xml` file is not copied from Hive and you would need to manually modify the `$SPARK_HOME/conf/hive-site.xml` file.

Related concepts

[Customizing Security in HPE Ezmeral Data Fabric](#) on page 1870

Describes the `.customSecure` file and how HPE Ezmeral Data Fabric 6.x handles custom security settings.

Spark SQL Thrift Server

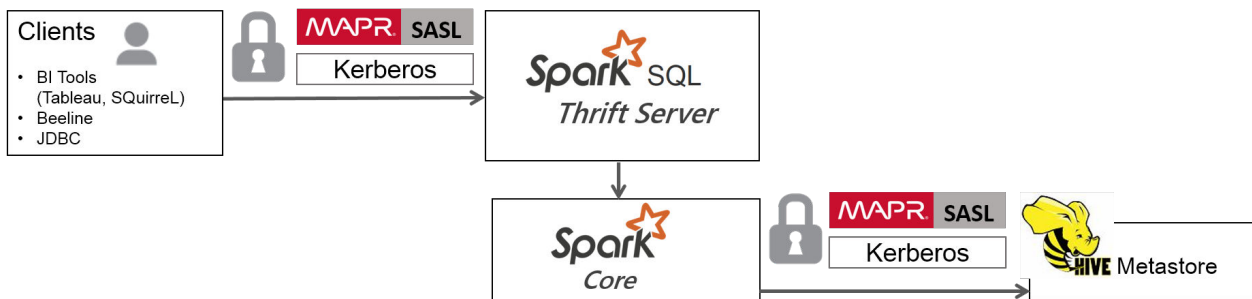

Spark SQL Thrift (Spark Thrift) was developed from Apache Hive HiveServer2 and operates like HiveServer2 Thrift server.

Spark Thrift is supported on secure clusters. You can run the Spark Thrift server and connect to Hive versions supported by Spark 2.1.0 and later with Business Intelligence (BI) tools or the Beeline command-line tool.

Starting in the EEP 4.0 release, the Spark Thrift server is available as a separate package. To install this package, see [Installing Spark Standalone](#) on page 222 or [Installing Spark on YARN](#) on page 224, depending on the type of cluster manager you are installing.

In EEP 3.0, MapR introduces additional security mechanisms for Spark with the Spark Thrift server. MapR-SASL and Kerberos are supported:

- For JDBC connections into Spark Thrift server
- Between Spark and Hive metastore

To enable these security mechanisms for the Spark Thrift server, starting in the EEP 4.0 release, for secure clusters, running `configure.sh -R` configures MapR-SASL security. The script modifies or creates a `SPARK_HOME/conf/hive-site.xml` file as follows:

- If Hive is installed in your cluster, the script copies `HIVE_HOME/conf/hive-site.xml` to `SPARK_HOME/conf` and modifies the file.
- If Hive is not installed and you are using MapR-SASL security, the script creates a new `SPARK_HOME/conf/hive-site.xml` file.
- Each time the script runs, if there is a pre-existing `SPARK_HOME/conf/hive-site.xml` file, the script saves a copy of the file in `SPARK_HOME/conf/hive-site.xml.old` before modifying it.

You can configure security manually by following the steps outlined in sub-topics listed on this page.

To launch the Spark Thrift server, perform the procedures required to configure [Apache Spark](#) on page 4501 to use [Hive](#) on page 4011.

! IMPORTANT:

- Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 10000.
- Starting in the EEP 5.0.4 and EEP 6.3.0 releases, if you start and stop the Spark Thrift server by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 2304.

Default Behavior

The default behavior of the Spark Thrift server is as follows:

1. After installation, the Spark Thrift server is started in the local master mode.
2. If the Spark master package is installed, then Spark Thrift server is started in the standalone master mode.
3. If the `spark.master` property is set in the `spark-defaults.conf` file, then Spark Thrift server uses the master set by this property.

Known Limitations

- MapR-SASL support is implemented for Spark 2.1.0 and later versions of Spark. For Spark version information, see [Component Versions for Released EEPs](#) on page 6600.
- The ODBC drivers do not support MAPR-SASL.
- Username and password authentication through PAM is not supported in EEP 3.0.
- Spark Thrift server supports only features and commands in Hive 1.2.
- Although Spark 2.1.0 can connect to Hive 2.1 Metastore, only Hive 1.2 features and commands are supported by Spark 2.1.0.

Spark Thrift Server Clients

With Spark Thrift server, you can use JDBC and ODBC connection interfaces that enable a variety of external tools to access Spark and run SQL queries.

- The ODBC interface is used by BI tools (often produced by HPE Ezmeral Data Fabric partners such as [Tableau](#) or [Microstrategy](#)).
- The JDBC interface is used by clients such as Squirrel SQL or the Beeline simple SQL shell.

MapR Hive JDBC clients that connect to HiveServer2 can also connect to Spark Thrift server without additional configuration. For details about clients, see [HiveServer2 Clients](#) and [Connecting to HiveServer2](#).

IMPORTANT: Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number is 10000. Beginning with EEP 6.3.0, the connection port number is 2304 for both start/stop methods (using Warden and using `thriftserver.sh` scripts).

MapR-SASL JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for MapR-SASL environments is:

```
jdbc:hive2://<hostname>:2304/default;auth=maprsasl;ssl=true
```

Otherwise, the port you use depends on the EEP version:

EEP 4.0 through 6.2.x	<code>jdbc:hive2://<hostname>:10000/default;auth=maprsasl;ssl=true</code>
EEP 6.3.0 and later	<code>jdbc:hive2://<hostname>:2304/default;auth=maprsasl;ssl=true</code>

Kerberos JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for clusters secured with Kerberos is:

```
jdbc:hive2://<hostname>:2304/default;principal=mapr/<FQDN@REALM>;ssl=true
```

Otherwise, the port you use depends on the EEP version:

EEP 4.0 through 6.2.x	<code>jdbc:hive2://<hostname>:10000/default;principal=mapr/<FQDN@REALM>;ssl=true</code>
EEP 6.3.0 and later	<code>jdbc:hive2://<hostname>:2304/default;principal=mapr/<FQDN@REALM>;ssl=true</code>

Starting the Thrift Server on a Custom Port

To start the Spark Thrift Server on a custom port, use the `hive.server2.thrift.port` option. For example, you can specify the following in the `/opt/mapr/spark/spark-2.4.4/conf/hive-site.xml` file:

```
<property>
<name>hive.server2.thrift.port</name>
<value>34512</value>
</property>
```

For more information, see the [Apache HiveServer2](#) documentation.

Using Authentication with Spark Thrift Server

Spark Thrift server supports both MapR-SASL and Kerberos authentication. The authentication method that you configure for the Spark Thrift server determines how the connection is secured. Clients might require additional configuration and specific connection strings based on the authentication type.

To enable authentication, see:

- [Configuring Spark Thrift Server with MapR-SASL](#) on page 4523
- [Configuring Spark Thrift Server with Kerberos](#) on page 4524

To configure PAM for Spark Thriftserver, run `configure.sh` on the secure cluster.

For information about Hive integration, see:

- [Integrate Spark SQL with Hive](#)
- [Setting Up HiveServer2](#)
- [Hive](#)
- [Spark Feature Support](#)

Configuring Spark Thrift Server with MapR-SASL

Describes how to enable and start the Spark Thrift server on all nodes.

You can configure Spark Thrift server to use MapR-SASL for its communications with various components on a secure data-fabric cluster. Minimal configuration is required.

NOTE: Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To manually enable MapR-SASL authentication on a non-secure cluster or in versions earlier than EEP 4.0:

1. Verify that the `hive.server2.authentication` property in `hive-site.xml` is set to the value, `MAPRSASL`.

```
<property>
  <name>hive.server2.authentication</name>
  <value>MAPRSASL</value>
</property>
```

2. Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

IMPORTANT: The data-fabric administrative user (generally, the account named `mapr`) should start the Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

Bringing up the Spark Thrift server on every node

When you start and stop Warden after enabling Spark or after running [configure.sh](#) on page 2684 or after installing a patch, Spark starts only on one (1) node and not on all nodes. This happens because by default, the Warden configuration file for Spark has the value `1` instead of `all`. For example:

```
# grep services /opt/mapr/conf/conf.d/warden.spark-thriftserver.conf
services=spark-thriftserver:1:cldb
```

To fix this issue permanently:

1. Modify `/opt/mapr/spark/spark-2.4.0/warden/warden.spark-thriftserver.conf` and change `l` to `all`:

```
# grep services /opt/mapr/spark/spark-2.4.0/warden/
warden.spark-thriftserver.conf
    services=spark-thriftserver:all:cldb
```

2. Run `/opt/mapr/server/configure.sh -R`.

The change is then propagated to the `/opt/mapr/conf/conf.d/warden.spark-thriftserver.conf` file.

Configuring Spark Thrift Server with Kerberos

You can configure Spark Thrift server to use Kerberos for its communications with various components on a secure MapR cluster if necessary.

NOTE: MapR clusters do not provide Kerberos infrastructure. The information in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

To enable Kerberos authentication:

1. Create a Kerberos identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file.
 - The `hive.keytab` file must be owned and readable only by the `mapr` user.
 - `FQDN@REALM` is case-sensitive.

```
# kadmin
    : addprinc -randkey mapr/<FQDN@REALM>
    : ktadd -k /opt/mapr/conf/hive.keytab mapr/<FQDN@REALM>
```

2. Configure the following properties in `hive-site.xml` on each node where HiveServer2 is installed:

Property	Value
<code>hive.server2.authentication</code>	KERBEROS
<code>hive.server2.authentication.kerberos.principal</code>	<code>mapr/FQDN@REALM</code> (where <code>mapr/FQDN@REALM</code> is the principal that you want to use for the Spark Thrift server)
<code>hive.server2.authentication.kerberos.keytab</code>	<code>/opt/mapr/conf/mapr.keytab</code> (where <code>/opt/mapr/conf/mapr.keytab</code> is path to the keytab that must be used)

```
<property>
  <name>hive.server2.authentication</name>
  <value>KERBEROS</value>
  <description>authenticationtype</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.principal</name>
  <value>mapr/FQDN@REALM</value>
  <description>Spark Thrift server principal. If _HOST is used as
the FQDN portion,
  it will be replaced with the actual hostname of the running
```

```
instance.
  </description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value>
  <description>Keytab file for Spark Thrift server principal</
description>
</property>
```

3. Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where HiveServer2 is installed:

NOTE: These configurations are listed in the portion of the file that begins with `if ["$MAPR_SECURITY_STATUS" = "true"];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env_override.sh](#) on page 2939.

Existing Configuration	Required Configuration
<code>MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"</code>	<code>MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid"</code>
<code>MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"</code>	<code>MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"</code>

4. Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/.`

IMPORTANT: The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

For information about working with HiveServer, see:

- [Setting Up HiveServer2](#)
- [Hive](#)

Configuring Spark Thrift Server Encryption

Spark Thrift server encryption is supported when authentication is enabled. You can configure encryption with MapR SASL or with SSL/TLS.

Configuring Encryption with MapR SASL or Kerberos

Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done using MapR Installer, the Installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To manually configure encryption with MapR-SASL or Kerberos authentication on a non-secure cluster or in versions earlier than EEP 4.0, complete the following steps:

1. Set the `hive.server2.thrift.sasl.qop` property in `hive-site.xml` to the value `auth-conf`. The SASL Quality of Protection (QOP), or `sasl.qop`, setting and the authentication with confidentiality (`auth-conf`) value support authentication:

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
</property>
```

2. Restart Spark Thrift server to apply the change:

IMPORTANT: The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files are owned by this user, and impersonation support (where applicable) functions correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

Configuring Encryption with SSL/TLS

To enable encryption with SSL/TLS:

1. Add the following properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

```
spark.ssl.enabled true
spark.ssl.fs.enabled true
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.protocol TLSv1.2
spark.ssl.keyStorePassword mapr123
spark.ssl.trustStorePassword mapr123
```

After the properties are added, event logs will indicate that the job is encrypted.

2. To connect using Beeline with encryption, add the following properties to the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file:

```
<property>
  <name>hive.server2.use.SSL</name>
  <value>true</value>
  <description>enable/disable SSL </description>
</property>

<property>
  <name>hive.server2.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
  <description>path to keystore file</description>
</property>

<property>
  <name>hive.server2.keystore.password</name>
  <value>mapr123</value>
  <description>keystore password</description>
</property>
```

- To start the Spark Thriftserver, use the following command:

```
/opt/mapr/spark/spark-<version>/sbin/start-thriftserver.sh --hiveconf
hive.server2.thrift.port=2304 --master yarn --deploy-mode client
```

The following example shows a connection string using Beeline (PAM+SSL):

```
./bin/beeline
Beeline version 1.2.0-mapr-1808-spark by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connecting to jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connected to: Spark SQL (version 2.1.0-mapr-mep-3.x-1808)
Driver: Hive JDBC (version 1.2.0-mapr-1808-spark)
Transaction isolation: TRANSACTION_REPEATABLE_READ
1: jdbc:hive2://node1.cluster.com:2304/default>
```

Enabling High Availability for Spark Thrift Server

With EEPs 5.0.4 or 6.3.0 and later, you can enable high availability for the Spark Thrift Server. Note the following characteristics of high availability for the Spark Thrift Server:

- Unlike a HiveServer2 high-availability (HA) configuration, all Spark Thrift Servers are in an active state. ZooKeeper keeps track of the Thrift Servers. ZooKeeper chooses one of them to work and makes a record of the choice. If one of the Thrift Servers goes down, ZooKeeper looks for another Thrift Server, makes a record, and works with it.
- After configuration, you can use Beeline to connect to the Spark Thrift Server on each node. The Control System displays one thrift server as active with the others on standby, but you can connect to any of them.
- If a Spark Thrift Server stops or fails, ZooKeeper removes the record for the failed Spark Thrift Server, and the client connects to the next one in the ZooKeeper list.
- At its core, the running Spark Thrift Server is a job that you can start in YARN mode. This makes it possible to configure queues for the Spark Thrift Server in a multi-tenant cluster if high availability is enabled. You can do this by using the `./sbin/start-thriftserver` script and applying the special properties that YARN provides for managing queues.
- You don't need to configure load balancing. Spark handles load-balancing automatically through the use of parallelized requests and efficient resource management.

To enable high availability, use the following steps:

- Install Spark Thrift Server on all the cluster nodes where it is needed:

On Ubuntu

```
apt-get install
mapr-spark-thriftserver
```

On Red Hat / CentOS

```
yum install mapr-spark-thriftserver
```

On SLES

```
zypper install
mapr-spark-thriftserver
```

2. Add the following properties to the `/opt/mapr/spark/spark-<spark_version>/conf/hive-site.xml` file on all the nodes where the Spark Thrift Server is installed

```
<property>
<name>hive.zookeeper.quorum</name>
<value><zk_host1_>,<zk_host_2>,...,<zk_host_n></value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value><zk_port></value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value><zk_namespace></value>
</property>
```

For example:

```
<property>
<name>hive.zookeeper.quorum</name>
<value>node1.cluster.com,node2.cluster.com,node3.cluster.com</value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value>5181</value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value>ts2-ts2</value>
</property>
```

NOTE: The values that you provide for the `hive.server2.zookeeper.namespace` property should be different for the `hive-site.xml` in the Spark and Hive directories.

- Restart the Spark Thrift Server to apply the changes following the script in the `.sbin` directory at `/opt/mapr/spark/spark-<spark_version>/` or by running a `maprcli` command on all configured nodes:

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

or

```
maprcli node services -nodes <host_1>,<host_2>,<host_n> -name
spark-thriftserver -action restart
```

- Launch the Zookeeper command line interface, and check the Spark Thriftserver znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

For example:

```
/opt/mapr/zookeeper/zookeeper-3.4.11/bin/zkCli.sh -server
node1.cluster.com:5181
ls /ts2-ts2
[serverUri=node1.cluster.com:2304;version=;sequence=0000000000]
```

- Using Beeline, you can connect to the Spark Thrift Server by using the following string:

```
beeline> !connect jdbc:hive2://<hostname -f>:5181/
default;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=<hive.server2.z
ookeeper.namespace>;
```

For example:

```
./bin/beeline
Warning: Unable to determine $DRILL_HOME
Beeline version 1.2.0-mapr-spark-MEP-6.0.0-1912 by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
Connecting to jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
20/03/29 21:38:19 WARN MaprSaslClient: SASL Server qopProperty:

```

 **NOTE:** High availability for the Spark Thrift Server can be used in conjunction with HiveServer2 high availability. For more information about HiveServer2 high availability, see [Enabling High Availability for Hive](#) on page 4152.

Spark History Server SSL

Describes how to enable SSL for Spark History Server.

 **NOTE:** For secure clusters, Spark History Server UI authentication is enabled by default. If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-<spark_version>/conf/spark-defaults.conf` files, the password from the `spark-defaults.conf` file is used

Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To configure SSL manually in a non-secure cluster or in versions earlier than EEP 4.0, add the following properties to the `spark-default.conf` file:

```
#HistoryServer https configure
spark.yarn.historyServer.address <Spark History Server node
hostname>:18480
spark.ssl.protocol tls
spark.ssl.historyServer.enabled true
spark.ssl.trustStore $MAPR_HOME/conf/ssl_truststore
spark.ssl.keyStore $MAPR_HOME/conf/ssl_keystore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.keyStorePassword <ssl-keystore-password>
```

 **NOTE:** If a cluster is secure and you use unsecured ports with HTTP, you will be automatically redirected to HTTPS with secure ports. For example, if on the secure cluster you go to `http://node1:18080`, you will be redirected to `https://node1:18480`.

HPE Ezmeral Data Fabric Database Connectors for Apache Spark

This section describes the HPE Ezmeral Data Fabric Database connectors that you can use with Apache Spark.

[Apache Spark](#) is a software framework that is used to process data in memory in a distributed manner. Spark is replacing MapReduce in many use cases. The HPE Ezmeral Data Fabric Database Connectors for Spark enable users to write applications that access HPE Ezmeral Data Fabric Database JSON and Binary tables.

Understanding the HPE Ezmeral Data Fabric Database OJAI Connector for Spark

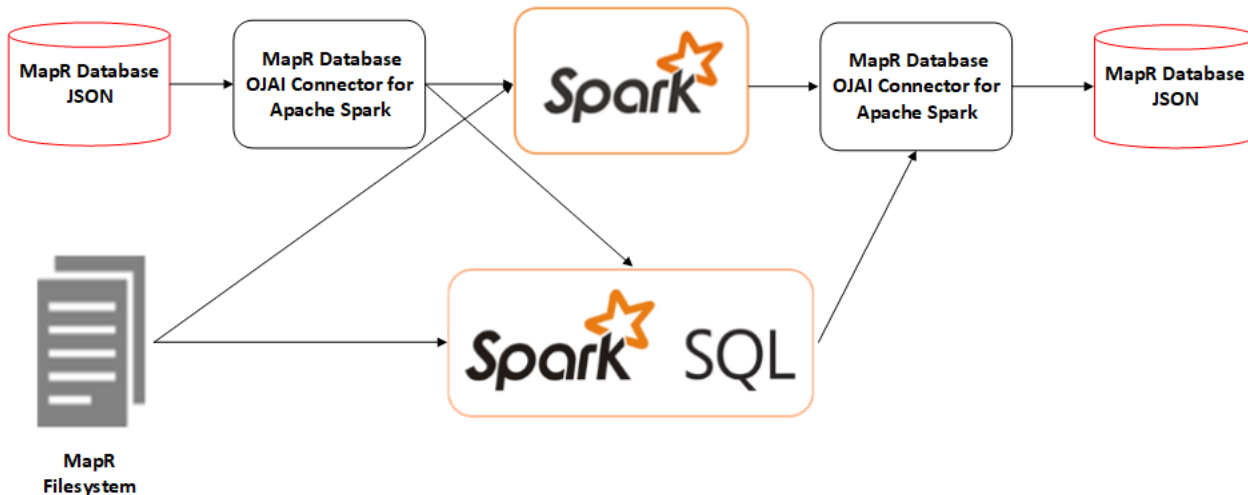

Using the HPE Ezmeral Data Fabric Database OJAI connector for Spark enables you build real-time and batch pipelines between your data and HPE Ezmeral Data Fabric Database JSON. Before getting started, it is important that you understand Spark terminology and workflow, system requirements and support, and OJAI connector and API features.

The HPE Ezmeral Data Fabric Database OJAI connector includes a set of APIs that enable you to write applications that consume HPE Ezmeral Data Fabric Database JSON tables and use them in Spark. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark is a companion to the [HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark](#) on page 4582, which provides the equivalent functionality for HPE Ezmeral Data Fabric Database Binary tables.

HPE Ezmeral Data Fabric Database OJAI Connector with Spark Workflow

You can use the HPE Ezmeral Data Fabric Database OJAI Connector to extract data from HPE Ezmeral Data Fabric Database or file system and transform that data using either Spark or Spark SQL, and then

load it into HPE Ezmeral Data Fabric Database JSON:

HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark Features

Principal features of the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark include the following:

- Support for Scala and, beginning with EEP 4.1, Java and Python APIs

This matrix shows the programming languages and features supported:

	Scala	Java	Python
RDD	Yes	Yes	No
DataFrame	Yes	Yes	Yes
Dataset	Yes	Yes	No
DStream	Yes	No	No

- APIs that enable you to load data from a HPE Ezmeral Data Fabric Database JSON table to an Apache Spark RDD, DataFrame, or Dataset
- Projection and filter pushdown for better performance
- Custom partitioner for RDDs that enables you to partition data for better performance
- APIs that save an Apache Spark RDD, DataFrame, or DStream to a HPE Ezmeral Data Fabric Database JSON table using either normal or bulk insert
- Support for Scala and Java bean classes
- Support for data locality
- Support for secondary indexes starting from EEP 7.0.0 and EEP 6.3.1.

The following features are not supported:

- HPE Ezmeral Data Fabric Database Binary tables

Only HPE Ezmeral Data Fabric Database JSON tables are supported; access to HPE Ezmeral Data Fabric Database binary tables is provided through the HPE Ezmeral Data Fabric Database Binary Connector.

- Secondary indexes are not supported for previous EEP 7.0.0 and EEP 6.3.1 versions.

Supported Product Versions and System Requirements

To use the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must have the following minimum software versions:

- MapR: 5.2.1 or later
- EEP 3.0 or later
- Spark 2.1.0 or later
- Scala 2.11 or later
- Java 8 or later

Support for DataFrames and Datasets is available starting in the EEP 4.0 release.

OJAI API

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark uses the [OJAI API](#) internally to access HPE Ezmeral Data Fabric Database JSON tables.

More information

[Spark Programming Guide](#)

[Spark SQL, DataFrames and Datasets Guide](#)

[Spark Streaming Programming Guide](#)

Configuring the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark

Before using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must edit the `pom.xml` file for your project.

Add the Spark core dependency into the `pom.xml` file:

NOTE: If all dependent JAR files are already present on the node, consider setting the `scope` parameter to `provided`. For example:

```
<scope>provided</scope>
```

Setting the scope this way reduces the size of the JAR file.

```
<dependency>
  <groupId>org.apache.spark</groupId>
  <artifactId>spark-core_<scala_version></artifactId>
  <version><spark_artifact_version></version>
</dependency>
```

Add the Spark Maven dependency to the `pom.xml` file:

```
<dependency>
  <groupId>com.mapr.db</groupId>
  <artifactId>maprdb-spark</artifactId>
  <version><spark_artifact_version></version>
</dependency>
```

For example, see the dependencies for Spark 2.4.4.0 (EEP 6.3.0 release):

```
<dependency>
  <groupId>org.apache.spark</groupId>
  <artifactId>spark-core_2.11</artifactId>
  <version>2.4.4.0-mapr-630</version>
```

```
</dependency>
<dependency>
  <groupId>com.mapr.db</groupId>
  <artifactId>maprdb-spark</artifactId>
  <version>2.4.4.0-mapr-630</version>
</dependency>
```

To enable Maven to download dependencies, add the following repository information to the `pom.xml` file:

```
<repository>
  <id>mapr-releases</id>
  <url>https://repository.mapr.com/maven/</url>
  <snapshots>
    <enabled>>false</enabled>
  </snapshots>
  <releases>
    <enabled>>true</enabled>
  </releases>
</repository>
```

Related concepts

[Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4631

Maven artifacts can be used for dependency management when developing applications based on the the HPE Ezmeral Data Fabric.

Loading Data from HPE Ezmeral Data Fabric Database Using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports loading data as an Apache Spark RDD. Starting in the EEP 4.0 release, the connector introduces support for Apache Spark DataFrames and Datasets. DataFrames and Datasets perform better than RDDs. Whether you load your HPE Ezmeral Data Fabric Database data as a DataFrame or Dataset depends on the APIs you prefer to use. It is also possible to convert an RDD to a DataFrame.

Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD

You can use the following API to load JSON-format data from a HPE Ezmeral Data Fabric Database table into an Apache Spark RDD of a JSON document:

Scala

For loading as an RDD, apply the following method on a `SparkContext` object:

```
def loadFromMapRDB[T](table: String):
  RDD[T]
```

Java

For loading as an RDD, apply the following method on a `MapRDBJavaSparkContext` object:

```
mapRDBSparkContext.loadFromMapRDB(tableName: String, clazz: Class)
```

NOTE: The only required parameter to the methods is `tableName`. All the others are optional.

The following example creates a `userprofilesRDD` by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table ("`/tmp/user_profiles`"):

Scala

```
import com.mapr.db.spark._
val userprofilesRDD
```

Java

```
= sc.loadFromMapRDB("/tmp/
user_profiles")
```

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
```

The following example creates a `userInfo` RDD by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table (`"/tmp/UserInfo"`):

Scala

```
import com.mapr.db.spark._

val userInfo =
sc.loadFromMapRDB("/tmp/UserInfo")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIIDocument> userInfo
=
mapRDBSparkContext.loadFromMapRDB("/tm
p/UserInfo")
```

In the previous example, the `userInfo` data contains the following information:

- Address (map type)
- Date of birth (date type)
- First name (string type)
- Interests (string type)
- Last name (string type)

The following prints the fields and shows the output for a sample user:

Scala

```
userInfo.foreach(println(_))
```

Java

```
usersInfo.foreach(System.out::println)
;
```

```
{
  "address":
    {"Pin":95035,"city":"milpitas","street":"350 holger way"},
  "dob":"1947-11-29",
  "first_name":"David",
  "interests":["football","books","movies"],
  "last_name":"Jones"
}
```

The following example shows a join operation performed on two different JSON documents using `address.city` as the join key:

Scala

```
import com.mapr.db.spark._

val maprd1 = sc.loadFromMapRDB("/tmp/
user_profiles")

val maprd2 = sc.loadFromMapRDB("/tmp/
user_income")

val collection = maprd1.map(a =>
(a.`address.city`[String],a))
.cogroup(maprd2.map(a=>(a.`address.cit
y`[String],a)))
.map(a =>
(a._1,a._2._1.size,a._2._2.size)).coll
ect
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import scala.Tuple2;
import scala.Tuple3;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument> maprd1 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
MapRDBJavaRDD<OJAIDocument> maprd2 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_income");

List collection =
maprd1.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a))
.cogroup(maprd2.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a)))
.map(a -> new Tuple3<>(a._1,
((Collection<?>)a._2._1).size(),
((Collection<?>)a._2._2).size()))
.collect();
```

The resulting RDD, `collection`, contains the count of the users in the `user_profiles` and `user_income` HPE Ezmeral Data Fabric Database tables.

The following example adds a new field into all the JSON documents:

Scala

```
import com.mapr.db.spark._

val maprd = sc.loadFromMapRDB("/tmp/
user_profiles")
val documents = maprd.map(a =>
{ a.`address.country` = "USA";
a}).collect
documents.saveToMapRDB("/tmp/
cleaned_user_profiles")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIDocument> maprd =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<OJAIDocument> documents =
maprd.map(a ->
{a.set("address.country", "USA");
return a;})

.collect();
mapRDBSparkContext.saveToMapRDB(docume
nts, "/tmp/cleaned_user_profiles");
```

Improving Performance by Using Projection Pushdown and Filter Pushdown

To improve performance, you can supply a `WHERE` clause and projection fields to the `loadFromMapRDB` API. In the following example, a condition is supplied to the `loadFromMapRDB` function and only certain fields are specified in the `SELECT` clause:

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")

.where([condit
ion])
.select("addre
ss",
"first_name",
"_id",
"last_name")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;
```

```

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/
user_profiles")

        .where([condition])

        .select("address",

                "first_name",

                "_id",

                "last_name");

```

The data is loaded based on the condition. The condition is pushed down to the server, and the server returns data based on the filtering. Only the fields specified in the SELECT clause are projected.

In the following example, the WHERE clause is used as a filter condition:

Scala

```

import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
        .where(field("salary") >= 100)

```

Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaSparkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/
user_profiles")
        .where(MapRDB.newCondition().is("salary",
QueryCondition.Op.GREATER_OR_EQUAL,
100));

```

The userprofilesRDD includes only those documents with a salary field greater than 100.

By specifying an _id field, you can find and retrieve a row for a given key:

Scala

```

import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")

```

```

                                .where(field("_id")
d") === "k2")

```

Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
                                .where(MapRDB.newCon
dition().is("_id",
QueryCondition.Op.EQUAL, "k2"));

```

WHERE Clause Semantics

The `loadFromMapRDB` API supports a WHERE clause to push down the filter to the JSON document API, ensuring that only relevant documents are propagated to the RDD.

You can use two options to provide the filter condition:

- Scala domain-specific language (DSL)
- `QueryCondition` (from OJAI API)

Following is an example of using `loadFromMapRDB` and supplying a condition by using Scala DSL:

Scala

```

Condition isDoe = field("last_name")
=== "Doe"
val userprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles").where(isDoe)

```

For more information about using Scala DSL, see [Scala DSL for Specifying Filter Conditions](#) on page 4540.

Following is an example of passing the condition using the `QueryCondition` API:

Scala

```

val maprd =
sc.loadFromMapRDB(tableName)
                                .where(MapRDB.newConditio
n()
                                .is("_id",
QueryCondition.Op.EQUAL, "k2")
                                .build())

```

Java

```

MapRDBJavaRDD rdd =
mapRDBJavaSparkContext.loadFromMapRDB(
tableName)
                                .where(MapRDB.newConditio
n().is("_id",

```

```
QueryCondition.Op.EQUAL,
"k2").build());
```

For more information about `QueryCondition`, see [Querying with Conditions](#) on page 3281.

NOTE: For additional information, see [Java Examples](#) in the source code.

Creating an Apache Spark RDD of a Class

When loading data as an Apache Spark RDD, if you have a custom class in your application, you can present the data as objects of your class.

Scala

You must define the custom class using Jackson semantics for Scala modules. The following example defines a custom `User` class:

```
case class User (@JsonProperty("_id")
id:String,

@JsonProperty("first_name")
firstName:String,

@JsonProperty("last_name") lastName:
String,
@JsonProperty("dob") dob:
ODate,

@JsonProperty("interests") interests:
List[String])
```

In the following example, by supplying `User` as a type parameter to the function while loading the HPE Ezmeral Data Fabric Database table, you can create an RDD of the `User` class:

```
val userprofilesRDD =
sc.loadFromMapRDB[User]("/tmp/
user_profiles")
      .where("conditio
n")
```

When specifying a bean class, the `SELECT` clause is unnecessary and is ignored.

Java

You must define a custom bean class as follows:

```
public static class Person implements
Serializable {
    private String _id;
    private String firstName;
    private String lastName;
    private Date dob;
    private Seq<String>
interests;
    public String get_id()
{ return _id; }
    public void set_id(String
_id) { this._id = _id; }
    public String
getFirstName() { return firstName; }
    public void
setFirstName(String firstName)
```

```

{ this.firstName = firstName; }
  public String
getLastName() { return lastName; }
  public void
setLastName(String lastName)
{ this.lastName = lastName; }
  public Date getDob()
{ return dob; }
  public void setDob(Date
dob) { this.dob = dob; }
  public Seq<String>
getInterests() { return interests; }
  public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
}

```

In the following example, by supplying the `User` bean class as a type parameter while loading the HPE Ezmeral Data Fabric Database table, you can create a `MapRDBJavaRDD` of the `User` class:

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles",
User.class).where(<condition>);

```

Scala DSL for Specifying Filter Conditions

When loading data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD, you can use Scala DSL to specify filter conditions. This section shows examples of these filter conditions.

In the following examples, a class named `field` is introduced to represent a field in a condition. The `field` condition takes an argument as a `String`. The following table shows conditions written using Scala DSL:

Condition	Example
equality	<code>val idOnlyPredicate = field("_id") === "k2"</code>
greaterThan	<code>val simplePredicateWithComparisonOperator = field("a.c.d") > 10</code>
notexists	<code>val simpleNotExistsPredicate = field("a.c.e") notexists</code>
IN	<code>val inPredicate = field("a.c.d") in Seq(ODate.parse("2011-05-21"), ODate.parse("2013-02-22"))</code>
typeof	<code>val simpleTypeOfPredicate = field("a.c.d") typeof "INT"</code>

Condition	Example
complex condition with and	<pre>val inPredicateWithMapAndArray = (field("a.c.d") in Seq(5,10)) and (field("a.c.e") notin Seq("aaa","bbb"))</pre>
another complex condition	<pre>val compositePredicateWithAndOnly = ((field("a.b") notexists) and (field("p.q") typeof "DATE")) and (field("a.c.d") > 20L)</pre>
between	<pre>val predicateWithBetweenOp = field("a.c.d") between (ODate.parse("2015-01-15"), ODate.parse("2015-05-15"))</pre>
predicate with equality check on Sequence of elements (representing array)	<pre>val eqPredicateWithList = field("a.b") === Seq(12345L, "xyz")</pre>
predicate with equality check on a map	<pre>val eqWithMapPredicate = field("a") === Map("k" -> "kite", "m" -> "map")</pre>

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- >
- >=
- <
- <=
- ===
- !=
- between
- exists
- notin
- in
- notexists
- typeof
- nontypeof
- like
- notlike

- matches
- notmatches
- sizeof

Here are examples for these operators:

- `field("a") > 10`
- `field("a") >= 10`
- `field("a") < 10`
- `field("a") <= 10`
- `field("a") === 10`
- `field("a") === Seq("aa", 10)`
- `field("a") === Map("aa" -> 10)`
- `field("a") != 10`
- `field("a") != Seq("aa", 10)`
- `field("a") != Map("aa" -> 10)`
- `field("a") between (10,20)`
- `field("a") exists`
- `field("a") notin Seq(10,20)`
- `field("a") in Seq(10, 20)`
- `field("a") notexists`
- `field("a") typeof "INT"`
- `field("a") nottypeof "INT"`
- `field("a") like "%s"`
- `field("a") notlike "%s"`
- `field("a") matches "*s"`
- `field("a") notmatches "*s"`

For `typeof`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`

- "STRING"
- "SHORT"
- "BYTE"
- "NULL"
- "FLOAT"
- "DOUBLE"
- "DECIMAL"
- "DATE"
- "TIME"
- "TIMESTAMP"
- "INTERVAL"
- "BINARY"
- "MAP"
- "ARRAY"

The `sizeOf` operator can have the following operations:

- `sizeOf(field("a")) == 10`
- `sizeOf(field("a")) < 10`
- `sizeOf(field("a")) > 10`
- `sizeOf(field("a")) >= 10`
- `sizeOf(field("a")) <= 10`
- `sizeOf(field("a")) != 10`

Java DSL for Specifying Filter Conditions

When loading data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD, you can use Java DSL to specify filter conditions. This section shows examples of these filter conditions.

Condition	Example
equality	<pre>QueryCondition equality = MapRDB.newCondition().is("_id", QueryCondition.Op.EQUAL, "k2").build();</pre>
greatherThan	<pre>QueryCondition greatherThan = QueryCondition simpleWithComparisonOperator = MapRDB.newCondition().is("a.b.c", QueryCondition.Op.GREATER, 10).build();</pre>

Condition	Example
notexists	<pre>QueryCondition notexists = MapRDB.newCondition().notExists("a.c.e").build();</pre>
IN	<pre>List<ODate> odateList = new ArrayList<>(); odateList.add(ODate.parse("2011-05-21")); odateList.add(ODate.parse("2013-02-22")); QueryCondition in = MapRDB.newCondition().in("a", odateList).build();</pre>
typeof	<pre>QueryCondition typeof = MapRDB.newCondition().typeof("a.c.d", Value.Type.INT).build();</pre>
complex condition with and	<pre>QueryCondition complexConditionWithAnd = MapRDB.newCondition() .and() .condition(MapRDB.newCondition().in("a", Arrays.asList(5, 10))) .condition(MapRDB.newCondition().notIn("b", Arrays.asList("aaa", "bbb"))) .close().build();</pre>
another complex condition	<pre>QueryCondition anotherComplexCondition = MapRDB.newCondition() .and() .condition(MapRDB.newCondition().notExists("a.b")) .condition(MapRDB.newCondition().typeof("p.q", Value.Type.DATE)) .condition(MapRDB.newCondition().is("a.c.d", QueryCondition.Op.GREATER, 20L)) .close().build();</pre>

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- is (LESS, LESS_OR_EQUAL, EQUAL, NOT_EQUAL, GREATER_OR_EQUAL, GREATER)
- equals
- and
- exists
- in
- like
- matches
- notEquals
- notExists
- notIn
- notLike
- notMatches

- `notTypeOf`
- `or`
- `sizeof`
- `typeof`

Here are examples for these operators:

- `MapRDB.newCondition().is("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.NOT_EQUAL, 10);`
- `MapRDB.newCondition().exists("a");`
- `MapRDB.newCondition().notIn("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().in("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().notExists("a");`
- `MapRDB.newCondition().typeof("a", Value.Type.INT);`
- `MapRDB.newCondition().notTypeOf("a", Value.Type.INT);`
- `MapRDB.newCondition().like("a", "%s");`
- `MapRDB.newCondition().notLike("a", "%s");`
- `MapRDB.newCondition().matches("a", "*s");`
- `MapRDB.newCondition().notMatches("a", "*s");`

For `typeof`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`
- `"STRING"`
- `"SHORT"`
- `"BYTE"`
- `"NULL"`

- "FLOAT"
- "DOUBLE"
- "DECIMAL"
- "DATE"
- "TIME"
- "TIMESTAMP"
- "INTERVAL"
- "BINARY"
- "MAP"
- "ARRAY"

The `sizeof` operator can have the following operations:

- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.NOT_EQUAL, 10);`

Using the Custom Partitioner with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark
In any distributed computing system, partitioning data is crucial to achieve the best performance. Apache Spark provides a mechanism to register a custom partitioner for partitioning the pipeline. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark includes a custom partitioner you can use to optimally partition data in an RDD.

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark's custom partitioner takes the following classes as keys:

- `String`
- `ByteBuffer` (as serializable `ByteBuffer`)

You can register this custom partitioner with either the `partitionBy` function or the `repartitionAndSortWithinPartitions` function.

The connector supports two versions of the custom partitioner. One version takes a HPE Ezmeral Data Fabric Database JSON table as an input. The partition information of the table is used to partition the data, so the `saveToMapRDB` call can use a `bulkInsert` to store the data. The `bulkInsert` option requires that you have the data already sorted on the `_id` key.

The other version of the custom partitioner takes an array of splits as an input.

Specifying tablename for the Partitioner

If you already have a table that has been created and partitioned based on a set of keys, you can specify that the RDD be partitioned in the same way (using the same set of keys). In the following example, `/srctable` is provided as a reference partitioner for `/dsttable`:

Scala

```
sc.loadFromMapRDB("/srctable")
    .keyBy(doc =>
doc._id[String])
    .repartitionAndSortWithinPartitions(MapRDBSpark.newPartitioner[String]("/dsttable"))
    .saveToMapRDB("/dsttable", createTable = false, bulkInsert = true)
```

Specifying a String Seq as an Array of Splits

In the following example, the first line creates an array of splits as `id1, id2 ... id9`. The rest of the example splits the RDD based on the array of splits:

Scala

```
val dstSplits: Array[String] = (1 to 9 by 3).map("id" + _).toArray
val partitionRDD =
sc.loadFromMapRDB("/srctable")
    .keyBy(doc =>
doc._id[String])
    .repartitionAndSortWithinPartitions(MapRDBSpark.newPartitioner[String](dstSplits))
    .saveToMapRDB("/dsttable", createTable = true, bulkInsert = true)
```

Specifying a ByteBuffer Seq as an Array of Splits

Suppose you have an array of byte buffers to use as the array of splits for the partitioner. You must convert the byte buffers to serializable byte buffers first:

Scala

```
// Converting bytebuffer to
serializable bytebuffer
val dstSplits =
arrayOfByteBuffer.map(x =>
MapRDBSpark.serializableBinaryValue(x)
)
sc.loadFromMapRDB("/srctable")
    //KeyBy serializable bytebuffer
    .keyBy(doc =>
doc.getBinarySerializable(binaryField)
)
    .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner(dstSplits))
    .saveToMapRDB("/dsttable",
createTable = true, bulkInsert = true)
```

Specifying tablename for the Partitioner with ByteBuffer as Id Fields

Suppose you have a table with keys that are binary or `ByteBuffer`, and you have an RDD with some rows and some values. You can repartition the RDD based on the partitions of the table. The following example reads the document from `/srctable`, but you could provide any table. In the second line, the example specifies a `keyBy` call on an ID that is binary serializable. In the last line, `/dsttable` is the RDD that has a key of serializable `ByteBuffers`:

Scala

```
sc.loadFromMapRDB("/srctable")
  .keyBy(doc =>
doc.getIdBinarySerializable())
  .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[ByteBuffer]
("/dsttable"))
```

NOTE: You must provide the key type of the `PairedRDD` on which the partitioning is specified. If the IDs are serializable bytebuffers, specify `ByteBuffer`. Otherwise, specify `String`.

After the data is partitioned with the custom partitioner, all the downstream transformations should be non-partition-changing transformations. Here is the code for passing on partitioner for an RDD:

Scala

```
user_profiles.repartitionAndSortWithin
Partitions
(MapRDBSpark.newPartitioner[String]
(<table-name>))
```

Or you can use the `partitionBy` function on the RDD:

Scala

```
user_profiles.partitionBy(MapRDBSpark.
newPartitioner[String](<table-name>))
```

The key of the data for this partitioner should be of the same type as that of the key of the table name. This partitioner yields a single partition if the table supplied to it is not pre-split. The number of partitions is calculated based on the table's existing tablet information.

For a table created with the `bulkInsert` option set to `true`, one of the following applies:

- If the table is pre-split, then the resulting partitions can be > 1 .
- If the table is no-split, then the resulting partitions will be 1 if no partition information is available from the RDD lineage.

Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark DataFrame

To load data from a HPE Ezmeral Data Fabric Database JSON table into an Apache Spark DataFrame, invoke the following API:

Scala

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](tableName:
String,
                      schema: StructType):
DataFrame

import com.mapr.db.spark.sql._
```

Java

```
val df
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles"): DataFrame
```

For loading as a DataFrame (Datasets of Row), apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB(tableName: String,
schema: StructType, sampleSize:
Double): DataFrame

import
com.mapr.db.spark.sql.api.java.MapRDBJavaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
maprSession.loadFromMapRDB("/tmp/
user_profiles");
```

NOTE: Java supports only DataSets of Row (`Dataset<Row>`).

Python

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
loadFromMapRDB(table_name, schema,
sample_size)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")
```

NOTE: PySpark supports only DataFrames (`Dataset<Row>`).

NOTE: The only required parameter to the methods is `tableName`. All the others are optional.

This creates a DataFrame object corresponding to the HPE Ezmeral Data Fabric Database table specified by the `tableName` parameter.

Both DataFrames and HPE Ezmeral Data Fabric Database tables work with structured data. DataFrames need a fixed schema, whereas HPE Ezmeral Data Fabric Database allows for a flexible schema. When loading data into a DataFrame, you can map your data to a schema by specifying the `schema` parameter in the `loadFromMapRDB` call. You can also provide an application class as the type `[T]` parameter in the call. These two approaches are the preferred methods for loading data into DataFrames.

For data exploration use cases, you might not know the schema of your HPE Ezmeral Data Fabric Database table. For those situations, the HPE Ezmeral Data Fabric Database OJAI connector for Apache Spark can infer the schema by sampling data from the table.

Whenever possible, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark [pushes projections and filters](#) for better performance. This allows HPE Ezmeral Data Fabric Database to project and filter data before returning it to your client application.

The following subtopics describe these techniques.

Optimizing HPE Ezmeral Data Fabric Database Lookups in Spark Jobs

The `lookupFromMapRDB()` API utilizes the primary and secondary indexes on a HPE Ezmeral Data Fabric Database table to optimize table lookups and outputs the results to an Apache Spark DataFrame.

! **IMPORTANT:** The `lookupFromMapRDB()` API functionality requires a patch. The patch works with EEP 6.2.0 (Core 6.1.0, Spark 2.4.0.0) and EEP 6.3.0 (Core 6.1.0, Spark 2.4.4.0). To install patches, see [Applying a Patch](#)

The `loadfromMapRDB()` API in [MapR Database Connectors for Apache Spark](#) is optimized to load massive amounts of data from HPE Ezmeral Data Fabric Database tables with high throughput. In cases where a Spark job needs to lookup a small number of documents based on the equality (or short range) condition on a primary or secondary key, the `lookupFromMapRDB()` API should be used.

Invoke the `lookupFromMapRDB()` API when the filter conditions in short range and equality queries reference primary and secondary keys. If the filter condition references any non-primary keys (fields other than the `_id` field), a secondary index must exist on the secondary keys. Indexes on the filtering keys is essential to achieving reasonable performance of lookup queries in HPE Ezmeral Data Fabric Database tables.

The `lookupFromMapRDB()` API uses the secondary keys in indexes to lookup values in the primary table. For example, if a query contains the filter conditions `mydate = '2012-03-26'` and `myid = '120026015'`, a [secondary index](#) (of type composite) created on the `mydate` and `myid` fields must exist for the query to quickly output results.

Examples on the following tabs demonstrate how to invoke the `lookupFromMapRDB()` API to perform a lookup in a HPE Ezmeral Data Fabric Database table and output the results to an Apache Spark DataFrame:

Scala

```
import com.mapr.db.spark.sql._
import spark.implicits._
val df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate" === "2012-03-26"
  && $"myid" === 120026015).show
```

Java

```
SparkSession sparkSession =
SparkSession.builder().getOrCreate();
MapRDBJavaSession mapRDBJavaSession =
new MapRDBJavaSession(sparkSession);
Dataset<Row> df2 =
mapRDBJavaSession.lookupFromMapRDB("/tbl");
df2.filter("mydate = '2012-03-26' and
myid = '120026015'").show();
```

Python

```
from pyspark.sql import SparkSession
df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate = '2012-03-26' and
myid = '120026015'").show()
```

Loading Data into a DataFrame Using an Explicit Schema

If you know the schema of your data, you can specify an explicit schema when loading a DataFrame.

The following example loads data into a user profile table using an explicit schema:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val addressSchema =
StructType(StructField("Pin",
IntegerType) ::

StructField("city", StringType) ::

StructField("street", StringType) ::
Nil)

val personSchema =
StructType(StructField("_id",
StringType) ::

StructField("first_name",
StringType) ::

StructField("last_name",
StringType) ::

StructField("address",
addressSchema) ::

StructField("interests",
ArrayType(StringType)) :: Nil)

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

StructField[] addressSchema = {
    new
StructField("Pin", IntegerType, true,
Metadata.empty()),
    new
StructField("city",StringType, true,
Metadata.empty()),
    new
StructField("street", StringType,
true, Metadata.empty())
};

StructField[] schemaFields = {
    new StructField("_id", StringType,
true, Metadata.empty()),
    new StructField("first_name",
StringType, true, Metadata.empty()),
    new StructField("address", new
StructType(addressSchema), true,
Metadata.empty()),
    new StructField("interests", new
ArrayType(StringType, true), true,
```

```

Metadata.empty()
    };
StructType personSchema = new
StructType(schemaFields);
MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles", personSchema);

```

Python

```

from pyspark.sql import SparkSession

addressSchema = [StructField("Pin",
IntegerType(), True),
                 StructField("city",
StringType(), True),

StructField("street", StringType(),
True)]
schemaFields = [StructField("_id",
StringType(), True),

StructField("first_name",
StringType(), True),

StructField("last_name",
StringType(), True),

StructField("address",
StructType(addressSchema), True),

StructField("interests",
ArrayType(StringType()), True)]
personSchema =
StructType(schemaFields)

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles", personSchema)

```

To create the DataFrame object named `df`, pass the schema as a parameter to the load call. Invoke the `loadFromMapRDB` method on a `SparkSession` object.

The resulting schema of the object is the following:

```

df.printSchema()
-----
root
|-- _id: String (nullable = true)
|-- first_name: String (nullable = true)
|-- last_name: String (nullable = true)
|-- address: Struct (nullable = true)
|   |-- Pin: integer (nullable = true)
|   |-- city: string (nullable = true)
|   |-- street: string (nullable = true)
|-- interests: array (nullable = true)
|   |-- element: string (containsNull = true)

```

When specifying `StructField` in a schema, optionally specify whether the field is nullable. In the example above, all fields are nullable.

Depending on the nullability of the field in the schema and the existence of fields in the HPE Ezmeral Data Fabric Database table, the load returns an `InvalidSchema` exception in the following cases:

- The schema contains a non-nullable field and the load attempts to put a NULL value into the field.
- The schema contains a non-nullable field and the field does not exist in the HPE Ezmeral Data Fabric Database table.
- The HPE Ezmeral Data Fabric Database table has fields that do not exist in the specified schema.

Loading Data into a DataFrame Using a Type Parameter

If the structure of your data maps to a class in your application, you can specify a type parameter when loading into a DataFrame.

Specify the application class as the type parameter in the load call. The load infers the schema from the class.

The following example creates a DataFrame with a `Person` schema by passing the `Person` class as the type parameter in the load call:

Scala

```
import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

    case class Person(_id:
String,
    First_name: String,
    last_name: String,
    Address: Address,
    Interests: Seq[String])

val df
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.Session;

public static class Address
implements Serializable {
    private Integer pin;
    private String street;
    private String city;

    public Integer getPin() { return
pin; }
    public void setPin(Integer pin)
{ this.pin = pin; }
    public String getStreet()
{ return street; }
    public void setStreet(String
street) { this.street = street; }
    public String getCity() { return
city; }
```

```

        public void setCity(String city)
        { this.city = city; }
    }
    public static class Person implements
    Serializable {
        private String _id;
        private String firstName;
        private String lastName;
        private Date dob;
        private Seq<String> interests;

        public String get_id() { return
        _id; }
        public void set_id(String _id)
        { this._id = _id; }
        public String getFirstName()
        { return firstName; }
        public void setFirstName(String
        firstName) { this.firstName =
        firstName; }
        public String getLastName()
        { return lastName; }
        public void setLastName(String
        lastName) { this.lastName =
        lastName; }
        public Date getDob() { return
        dob; }
        public void setDob(Date dob)
        { this.dob = dob; }
        public Seq<String>
        getInterests() { return interests; }
        public void
        setInterests(Seq<String> interests)
        { this.interests = interests; }
    }
    MapRDBJavaSession maprSession = new
    MapRDBJavaSession(sparkSession);
    Dataset<Row> df =
    maprSession.loadFromMapRDB(tableName,
    Person.class);

```

You must invoke the `loadFromMapRDB` method on a `SparkSession` or `MapRDBJavaSession` object.

All fields in an application bean class are nullable by default. The only circumstance in which the load returns an `InvalidSchema` exception is if the HPE Ezmeral Data Fabric Database table contains fields not included in the bean class.

The resulting schema of the object is as follows:

```

df.printSchema()
-----
root
|-- _id: String (nullable = true)
|-- first_name: String (nullable = true)
|-- last_name: String (nullable = true)
|-- address: Struct (nullable = true)
|   |-- Pin: integer (nullable = true)
|   |-- street: string (nullable = true)
|   |-- city: string (nullable = true)
|-- interests: array (nullable = true)
|   |-- element: string (containsNull = true)

```

Loading Data into a DataFrame Using Schema Inference

If you do not know the schema of the data, you can use schema inference to load data into a DataFrame. This section describes how to use schema inference and restrictions that apply

When you do not specify a schema or a type when loading data, schema inference triggers automatically. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark internally samples documents from the HPE Ezmeral Data Fabric Database JSON table and determines a schema based on that data sample. By default, the sample size is 1000 documents. Alternatively, you can specify a sample size parameter. The parameter is optional in the `loadFromMapRDB` call and is named `sampleSize`. The following example specifies using a sample size of 100 documents:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df =
sparkSession.loadFromMapRDB(tableName,
sampleSize : 100)
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJavaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB(tableName,
100);
```

Python

```
from pyspark.sql import SparkSession

df = spark.loadFromMapRDB(table_name,
100)
```

 **IMPORTANT:** Because schema inference relies on data sampling, it is non-deterministic. It is not well suited for production use where you need predictable results. Inferring schema results in reading sample rows from the table, hence execution time varies with number of rows in the source table.

Sampling Using Reader Functions

An alternative to sampling data using the `loadFromMapRDB` call is to use reader functions.

To use the DataFrame reader function (for Scala only), call the following methods:

```
val df = sparkSession.read.maprdb(tableName)
```

To use the reader function with basic Spark, call the `read` function on a `SQLContext` object as follows:

Scala

```
import org.apache.spark.sql.SQLContext

val df =
sqlContext.read.format("com.mapr.db.spark.sql")
.option("tableName",
```

```
<table-name>
    .option("sampleSize",
100).load()
```

Java

```
import
org.apache.spark.sql.SQLContext;

Dataset<Row> df = sqlContext.read()
    .format("com.mapr.db
.spark.sql")
    .option("tableName",
<table-name>).load();
```

Python

```
from pyspark.sql import SQLContext

df = sql_context.read\
    .format("com.mapr.db.spark.sql.De
faultSource")\
    .option("tableName",
<table-name>).load()
```

Type Conflict Resolution When Sampling

When sampling data during schema inference, you might encounter conflicting value types within a field. The connector uses the following rules to resolve type conflicts:

- If the two conflicting types are each one of the following, the resolved type is the wider of the two types:
 - `ByteType`
 - `ShortType`
 - `IntegerType`
 - `LongType`
 - `FloatType`
 - `DoubleType`

The type list above is arranged in increasing order of width. For example, if one document contains a field of type `ByteType` and the other contains a field of type `FloatType`, the resultant type is `FloatType`.

- If one of the types is `DecimalType`, then the resultant type is `DecimalType`, if and only if `DecimalType` is the wider of the two types.
- If the two types are `StructType`, each with different fields, then the resultant type is a new `StructType` that contains all the fields in each `StructType`.
- If the two types are `ArrayType`, each with different element types, then the resultant type is a new `ArrayType` where the type of the elements in the array is resolved using the aforementioned rules.
- If none of the above rules can be used for resolving type conflicts, then during data conversion, the load reports a `ConflictType` exception.

Suppose `Name` contains `String` values in some rows and a map with `first_name` and `last_name` as nested fields in other rows. During schema inference, the conflict resolution logic encounters two different types for the same field, `StringType` and `MapType`. It will note the conflict and return a `ConflictType` exception later when converting the data during the load.

By default, conflict exceptions occur during data conversion. To change this so that the exception is returned during the conflict resolution stage, set the `FailOnConflict` option to `true` :

Scala

```
val df =
  spark.read.maprdb(<tableName>,
    Map("sampleSize" -> 100,
      "FailOnConflict" -> true))
```

Invalid Schemas

When using schema inference, missing and extra fields are resolved in the following ways:

- If a field in the inferred schema is missing in the HPE Ezmeral Data Fabric Database JSON document, the field is set to null.
- If there are fields in a HPE Ezmeral Data Fabric Database JSON document that are not in the inferred schema, the load returns an `InvalidSchema` exception.

Type Mapping Between HPE Ezmeral Data Fabric Database JSON and DataFrames

This table maps data types between HPE Ezmeral Data Fabric Database JSON OJAI and Apache Spark DataFrame.

NOTE: Not all DataFrame data types are supported by HPE Ezmeral Data Fabric Database, for a list of supported data types, see [JSON Documents](#) on page 596.

OJAI Data Type	DataFrame Data Type
Boolean	BooleanType
String	StringType
Byte	ByteType
Short	ShortType
Int	IntegerType
Long	LongType
Float	FloatType
Double	DoubleType
Decimal	DecimalType
Date	DateType
Time	TimestampType
TimeStamp	TimeStampType
Interval	CalendarIntervalType
Binary	BinaryType
Map	StructType
Array	ArrayType

NOTE: The OJAI `Time` data type is converted to a Spark `TimestampType` with the date set to the epoch date. Spark SQL does not support a `TIME` type.

Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark Dataset

You can use one of three ways to load data from HPE Ezmeral Data Fabric Database into an Apache Spark Dataset:

- Load the data into a Dataset.
- Load the data into a DataFrame, and then convert it to a Dataset.
- Load the data into a Dataset using a custom encoder.

Load into a Dataset

Scala

For loading as a Dataset, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](table: String,
  schema : StructType).as [T]: Dataset

import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles").as [T]: Dataset
```

Java

For loading as a Dataset, apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB[T <:
  java.lang.Object](tableName: String,
  schema: StructType, sampleSize:
  Double, clazz: Class[T]): Dataset[T]

import
  com.mapr.db.spark.sql.api.java.MapRDBJavaSession;

MapRDBJavaSession maprSession = new
  MapRDBJavaSession(sparkSession);

Dataset<Row> ds =
  maprSession.loadFromMapRDB("/tmp/
  user_profiles");
```

NOTE: The only required parameter to the methods is `tableName`. All the others are optional.

Load into DataFrame and Convert to Dataset

To load the data as a DataFrame, see [Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark DataFrame](#) on page 4548. To convert the DataFrame to a Dataset, use the `as[<type>]` method. The `<type>` can be any of the basic types in Scala.

The following code example creates a `Dataset[Person]` using the `as[<type>]` method:

Scala

```
import
  org.apache.spark.sql.SparkSession
```

Java

```
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

case class Person (_id:String,
first_name:String,
last_name: String, dob:
java.sql.Date,
Interests: Seq[String,
address: Address)

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
```

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

public static class Address
implements Serializable {
private Integer pin;
private String street;
private String city;

public Integer getPin() { return
pin; }
public void setPin(Integer pin)
{ this.pin = pin; }
public String getStreet()
{ return street; }
public void setStreet(String
street) { this.street = street; }
public String getCity() { return
city; }
public void setCity(String city)
{ this.city = city; }
}

public static class Person implements
Serializable {
private String _id;
private String firstName;
private String lastName;
private Date dob;
private Seq<String> interests;
public String get_id()
{ return _id; }
public void
set_id(String _id) { this._id = _id; }
public String
getFirstName() { return firstName; }
public void
setFirstName(String firstName)
{ this.firstName = firstName; }
public String
getLastName() { return lastName; }
public void
setLastName(String lastName)
{ this.lastName = lastName; }
```

```

        public Date getDob()
    { return dob; }
        public void setDob(Date
dob) { this.dob = dob; }
        public Seq<String>
getInterests() { return interests; }
        public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
    }
    Dataset<Person> ds =
    maprSession.loadFromMapRDB(tableName,
    Person.class);

```

Load into Dataset Using Custom Encoder

You can create a custom encoder for Java bean classes by calling the `Encoders.bean` method.

`Encoders.bean` only support Java classes. To create a `Dataset` of the Scala class, the previous code can be used. The following example shows how to load into a `Dataset` by creating a custom encoder for a Java class named `beanClass`:

Scala

```

import
org.apache.spark.sql.SparkSession

import com.mapr.db.spark.sql._

val ds =
sparkSession.loadFromMapRDB("/tmp/
user_profiles")
        .as(Encoders.bean(beanClass))

```

Java

```

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(beanC
lass));

```

Filter Pushdown

After you have loaded data into a `Dataset`, you can apply filter pushdowns. The following example filters on `first_name`:

Scala

```
ds.filter($"first_name" === "David")
```

Java

```
ds.filter(col("first_name").equalTo("D
avid")).show();
```

See [Projection and Filter Pushdown with Apache Spark DataFrames and Datasets](#) on page 4560 for other examples.

Projection and Filter Pushdown with Apache Spark DataFrames and Datasets

Projection and filter pushdown improve query performance. When you apply the `select` and `filter` methods on DataFrames and Datasets, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark pushes these elements to HPE Ezmeral Data Fabric Database where possible.

Projection Pushdown

Projection pushdown minimizes data transfer between HPE Ezmeral Data Fabric Database and the Apache Spark engine by omitting unnecessary fields from table scans. It is especially beneficial when a table contains many columns.

When you invoke the following `select` method on a DataFrame, the connector pushes the projection:

Scala

```
import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.select("_id", "first_name",
"last_name");
```

Python

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

The equivalent example using Datasets is as follows:

Scala

```
import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.select("_id", "first_name",
"last_name")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
```

```
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles", Person.class);
ds.select("_id", "first_name",
"last_name");
```

Filter Pushdown

Filter pushdown improves performance by reducing the amount of data passed between HPE Ezmeral Data Fabric Database and the Apache Spark engine when filtering data.

Consider the following example:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.filter("first_name = 'Bill'")
```

Python

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark pushes the filter `firstName = 'Bill'` down to HPE Ezmeral Data Fabric Database.

The equivalent example using Datasets is as follows:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
```

```
( "/tmp/user_profiles" ).as[Person]
ds.filter($"first_name" === "Bill")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

Dataset ds =
maprSession.loadFromMapRDB( "/tmp/
user_profiles" ).as(Encoders.bean(Perso
n.getClass()));
ds.filter(col("first_name").equalTo("B
ill"));
```

The following DataFrame filters those rows in which first_name is either "David" or "Peter":

Scala

```
df.filter($"first_name" === "David"
|| $"first_name" === "Peter")
```

Java

```
df.filter(col("first_name").equalTo("D
avid").or(col("first_name").equalTo("P
eter")))
```

Python

```
df.filter((col("first_name") ==
"David") | (col("first_name") ==
"Peter"))
```

The following DataFrame retrieves only the rows in which the first_name is "David" and the last_name is "Jones":

Scala

```
df.filter($"first_name" === "David"
&& $"last_name" === "Jones")
```

Java

```
df.filter(col("first_name").equalTo("D
avid").and(col("last_name").equalTo("J
ones")))
```

Python

```
df.filter((col("first_name") ==
"David") & (col("last_name") ==
"Jones"))
```

The following uses a not condition to return rows where the first_name is not "David" and the last_name is not "Peter":

Scala

```
df.filter(not($"first_name" ===
"David" || $"last_name" === "Peter"))
```

Java

```
df.filter(not(col("first_name").equalTo("David").or(col("last_name").equalTo("Peter"))))
```

Python

```
df.filter(~((col("first_name") == "David") | (col("last_name") == "Peter")))
```

The HPE Ezmeral Data Fabric Database OJAI Connector pushes down all of the filters shown in the earlier examples. It can push down the following types of filters, provided that the field is not an `Array` or `Map`:

- Equal To (=)
- Not Equal To (!=)
- Less Than (<)
- Less Than or Equal To (<=)
- Greater Than (>)
- Greater Than or Equal To (>=)
- In Predicate (IN)
- Like predicate (LIKE)
- AND, OR
- NOT

Restrictions

Pushdowns with DataFrames and Datasets are not supported in the following scenarios:

- Filters on complex types, including arrays, maps, and structs

For example, a filter on a field in a map, as shown in the following example, is not pushed down:

Scala

```
df.filter($"address.city" === "Milpitas")
```

Java

```
df.filter(col("address.city").equalTo("Milpitas"));
```

Python

```
df.filter(col("address.city") == "Milpitas")
```

- Filters with functions `sizeof`, `typeof`, and `matches`
Spark SQL does not support these functions.
- Projections on complex types, including arrays, maps, and structs

For example, if you select an element of an array, as shown in the following example, it is not pushed down:

Scala

```
ds.select($"hobbies" (0))
```

Java

```
df.select(col("hobbies").getItem(0));
```

Python

```
df.select(col("hobbies").getItem(0))
```

These limitations do not apply to pushdowns on RDDs. An alternative is to apply the [pushdown using an RDD](#), and then [convert the RDD to a DataFrame](#).

NOTE: HPE Ezmeral Data Fabric Database 6.0 introduces support for [Secondary Indexes](#) on page 635, but the HPE Ezmeral Data Fabric Database OJAI Connector for Spark does not currently leverage them.

Converting an Apache Spark RDD to an Apache Spark DataFrame

When APIs are only available on an Apache Spark RDD but not an Apache Spark DataFrame, you can operate on the RDD and then convert it to a DataFrame.

You can convert an RDD to a DataFrame in one of two ways:

- Use the helper function, `toDF`.
- Convert the RDD to a DataFrame using the `createDataFrame` call on a `SparkSession` object.

Using the `toDF` Helper Function

The `toDF` method is available through `MapRDBTableScanRDD`. The following example loads an RDD that filters on `first_name` equal to "Peter" and projects the `_id` and `first_name` fields, and then converts the RDD to a DataFrame:

Scala

```
import com.mapr.db.spark.sql._

val df =
  sc.loadFromMapRDB(<table-name>)
    .where(field("first_name")
      === "Peter")
    .select("_id",
      "first_name").toDF()
```

Using `SparkSession.createDataFrame`

With this approach, you can convert an `RDD[Row]` to a `DataFrame` by calling `createDataFrame` on a `SparkSession` object. The API for the call is as follows:

Scala

```
def createDataFrame(RDD, schema:
  StructType)
```

You might need to first convert an `RDD[OJAIDocument]` to an `RDD[Row]`. The following example shows how to do this:

Scala

```
val df = sparkSession.createDataFrame(
  rdd.map(doc
=>MapRDBSpark.docToRow(doc, schema)),
  schema)
```

`rdd` is of type `RDD[OJAIDocument]`. The `docToRow` call converts `rdd` to an `RDD[Row]` that is then passed to `createDataFrame`.

Working with Complex JSON Document Types

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides APIs to process JSON documents loaded from HPE Ezmeral Data Fabric Database.

Suppose you want to calculate the number of users located in each city:

Scala

```
import com.mapr.db.spark.sql._

val customerprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
val numberOfCustaccCities =
customerprofilesRDD.map(a =>
(a.`address.city`[String],a))
                                                                    .groupByKe
y()
                                                                    .map(a =>
(a._1, a._2.size))
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import scala.Tuple2;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
JavaRDD numberofCustaccCities =
customerprofilesRDD.mapToPair
(a -> new
Tuple2<>(a.getString("address.city"),
a)).groupByKey()
.map(a -> new Tuple2<>(a._1,
((Collection<?>)a._2).size()));
```

If you have not provided an explicit cast, then the object is returned as `AnyRef`. To access methods specific to a class, such as `String` or `Integer`, you can cast it to a specific type later in the process.

Now suppose you want to collect all the addresses (address is of type `Map`) of all customers:

Scala

```
import com.mapr.db.spark.sql._

val customerprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles")
val customersAddress =
```

```
customerprofilesRDD.map(a =>
a.address).collect
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAI Document>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<String> customersAddress =
customerprofilesRDD.map(a ->
a.getString("address")).collect();
```

customersAddress contains all of the addresses, but is returned as an AnyRef object.

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark introduces three new classes to wrap complex JSON types:

Class	Type
DBMapValue	Map[String, AnyRef]
DBArrayValue	Array[AnyRef]
DBBinaryValue	ByteBuffer

These classes are not exposed; however, you can access the underlying elements of DBArrayValue and DBMapValue by using the same functions as in Seq and Map. DBArrayValue works like a sequence, while DBMapValue works like a map.

DBBinaryValue is a class wrapper around ByteBuffer. ByteBuffer is not serializable, so you will get serialization errors if you use the ByteBuffer in Spark code. You must ensure that byte buffers are converted to DBBinaryValue or serialized byte buffers. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides an API to convert ByteBuffers to serializable byte buffers.

Accessing Values in a Map

DBMapValue is a type of Map[String, AnyRef]. Any functions that you can use to access values in the Map, you can also use to access values in DBMapValue. In the following example, customeraddress contains the address of the customers who reside in San Jose. customeraddress is an Array[DBMapValue]:

Scala

```
val customerAddress = maprd.map(a =>
a.address[Map[String, AnyRef]])
    .filter(a => a!= null &&
a.get("city").contains("San Jose"))
    .collect
```

This example can also be written in Scala using a functional approach as follows:

Scala

```
val customerAddress = maprd.map(a
=> (a.address[Map[String, AnyRef]],
a).join(my_documents)
    .filter(a =>
```

```
Option(a).map(a =>
a.get("city").contains("San
Jose")).getOrElse(false))
.collect
```

NOTE: You can push the condition specified in the filter condition to the HPE Ezmeral Data Fabric Database table scan by using the `where` clause.

Accessing the Array JSON Object

This example uses a sequence to access the Array JSON object:

Scala

```
val custInterests = maprd.map(a =>
a.interests[Seq[AnyRef]])
    .filter(a => a !=
null && a(0) == "sports")
    .collect
```

ByteBuffer Serialization

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to enable serialization of the `ByteBuffer`:

Scala

```
MapRDBSpark.serializableBinaryValue(byteBuffer)
```

The following example shows an array of byte buffers or binary values that are converted to serialized byte buffers by using `MapRDBSpark.serializableBinaryValue`:

Scala

```
val dstSplits =
arrayOfByteBuffer.map(x =>
MapRDBSpark.serializableBinaryValue(x)
)
```

Saving Data to a HPE Ezmeral Data Fabric Database JSON Table

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides an API to save an Apache Spark RDD to a HPE Ezmeral Data Fabric Database JSON table. Starting in the EEP 4.0 release, the connector introduces support for saving Apache Spark DataFrames and DStreams to HPE Ezmeral Data Fabric Database JSON tables.

Saving an Apache Spark RDD to a HPE Ezmeral Data Fabric Database JSON Table

Saving an RDD[OJAIDocument] to HPE Ezmeral Data Fabric Database

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to save an `RDD[OJAIDocument]` to a HPE Ezmeral Data Fabric Database table:

Scala

For saving an RDD, apply the following method on the RDD:

```
def saveToMapRDB(tablename: String,
createTable: Boolean =
false, bulkInsert: Boolean =
```

```
false, idFieldPath: String =
DocumentConstants.ID_KEY) : Unit
```

Java

For saving an RDD, apply one of the following methods on a `MapRDBJavaSparkContext` object:

```
def saveToMapRDB[D](javaRDD:
JavaRDD[D], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveRowRDDToMapRDB(javaRDD:
JavaRDD[Row], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveToMapRDB[K, V <: AnyRef]
(javaPairRDD: JavaPairRDD[K, V],
keyClazz: Class[K], valueClazz:
Class[V], tableName: String,
createTable: Boolean, bulkInsert:
Boolean): Unit
```

NOTE: The only required parameter to the methods is `tableName`. All the others are optional.

In the following example, `address` and `first_name` data is loaded from the `"/tmp/user_profiles"` table, stored as an RDD (`userprofilesRDD`), and then saved to the `"/tmp/user_firstname_and_address"` table:

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")

      .where("condition
")
      .select("address"
, "first_name")

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
      .where("condition")
      .select("address",
"first_name");
```

```
mapRDBSparkContext.saveToMapRDB(userprofilesRDD, "/tmp/
user_firstname_and_address", true,
false, "_id");
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert an RDD[OJAIDocument] to a HPE Ezmeral Data Fabric Database table:

 **NOTE:** The `insertToMapRDB` API is available starting in the EEP 4.1.0 release.

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
userprofilesRDD.insertToMapRDB(tablename, createTable = true, bulkInsert =
false, idFieldPath = "_id")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD<OJAIDocument>
userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
mapRDBSparkContext.insertRowRDDToMapRD
B(userprofilesRDD, tablename);
```

 **NOTE:** The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

This API supports the following parameters:

Scala

Parameter	Default	Description
tableName	Not applicable	The name of the HPE Ezmeral Data Fabric Database table in which you are saving the document.
createTable	false	Creates the table before saving the documents. Note that if the table already exists and <code>createTable</code> is set to true, the API throws an exception.
idFieldPath	_id	Specifies the key to be used for the document.

Parameter	Default	Description
bulkInsert	false	Loads a group of rows simultaneously. bulkInsert is similar to a bulk load in MapReduce.

Java

Parameter	Default	Description
RDD (JavaRDD or JavaPairRDD)	Not applicable	Specifies the RDD which you are saving to the HPE Ezmeral Data Fabric Database table.
tableName	Not applicable	Specifies the name of the HPE Ezmeral Data Fabric Database table in which you are saving the document.
createTable	false	Creates the table before saving the document. Note that if the table already exists and createTable is set to true, the API throws an exception.
idFieldPath	_id	Specifies the key to be used for the document.
bulkInsert	false	Loads a group of rows simultaneously. bulkInsert is similar to a bulk load in MapReduce.
keyClazz (Only for JavaPairRDD)	Not applicable	Specifies the class type which is the key in the JavaPairRDD which you are saving into the HPE Ezmeral Data Fabric Database table.
valueClazz(Only for JavaPairRDD)	Not applicable	Specifies the class type which is the value in the JavaPairRDD which you are saving into the HPE Ezmeral Data Fabric Database table.

In Java, `saveToMapRDB` method works with `JavaRDD` and `JavaPairRDD`. For saving `JavaRDD[Row]`, use the `saveRowRDDToMapRDB` method.

The following example specifies a key by using the `idFieldPath` parameter and the `bulkInsert` value to save the RDD:

Scala

```
import com.mapr.db.spark._

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address",

idFieldPath = "user_id",

bulkInsert = false)
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
```

```
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
mapRDBSparkContext.saveToMapRDB(userprofilesRDD, "/tmp/
user_firstname_and_address", false,
false, "user_id");
```

The following example saves an RDD of `Person` objects into the newly created `/tmp/Userinfo` table:

Scala

```
import com.mapr.db.spark._

val sparkConf =
new SparkConf().setAppName("json
app").setMaster("local[*]")
val sc = new SparkContext(sparkConf)
val people =
sc.parallelize(getUsers())
people.saveToMapRDB("/tmp/UserInfo",
createTable= true)
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

SparkConf sparkConf = new
SparkConf().setAppName("json
app").setMaster("local[*]");
SparkContext sc = new
SparkContext(sparkConf);
JavaRDD rdd =
sc.parallelize(getUsers());
mapRDBSparkContext.saveToMapRDB(rdd,
"/tmp/UserInfo", true);
```

The following example shows the `getUsers` function that allocates the `Person` objects:

Scala

```
def getUsers(): Array[Person] = {
  val users: Array[Person] =

    Array(
      Person("DavUSCalif", "David",
"Jones",
        ODate.parse("1947-11-29"),
        Seq("football", "books",
"movies"),
        Map("city" -> "milpitas",
"street" -> "350 holger way",
"Pin" -> 95035)),
      Person("PetUSUtah", "Peter",
"pan",
        ODate.parse("1974-1-29"),
        Seq("boxing", "music",
"movies"),
        Map("city" -> "salt lake",
"street" -> "351 lake way", "Pin" ->
89898)),
```

```

        Person("JamUSAriz", "James",
"junior",
            ODate.parse("1968-10-2"),
            Seq("tennis", "painting",
"music"),
            Map("city" -> "phoenix",
"street" -> "358 pond way", "Pin" ->
67765)),

        Person("JimUSCalif", "Jimmy",
"gill",
            ODate.parse("1976-1-9"),
            Seq("cricket",
"sketching"),
            Map("city" -> "san jose",
"street" -> "305 city way", "Pin" ->
95652)),

        Person("IndUSCalif",
"Indiana", "Jones",
            ODate.parse("1987-5-4"),
            Seq("squash", "comics",
"movies"),
            Map("city" -> "sunnyvale",
"street" -> "35 town way", "Pin" ->
95985)))

    users
}

```

Saving a JSON Document to HPE Ezmeral Data Fabric Database

To save a JSON document using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must first convert the JSON document into an OJAI document and then save the RDD, as shown in the following example:

Scala

```

import com.mapr.db.spark._

val documents = sc.parallelize((1 to
10)
    .map(i => s""{"_id":
"$i", "test": "$i}""))
val maprd = documents.map(a =>
MapRDBSpark.newDocument(a))
maprd.saveToMapRDB("/tmp/testData")

```

Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.api.java.JavaSparkCon
text;

JavaRDD<String> documents =
JavaSparkContext.fromSparkContext(sc)
    .parallelize(Arrays.asList
(1, 2, 3, 4, 5, 6, 7, 8, 9, 10))
    .map(i -> { return

```

```

"{\"id\": \"\" + i + "\", \"test\":
\"\" + i + "\"}"; });
JavaRDD<OJAI Document> maprd =
documents.map(MapRDBSpark::newDocument
);
mapRDBSparkContext.saveToMapRDB(maprd,
"/tmp/testData");

```

An `_id` field is required to save JSON data into a table, so an `_id` field must be present. If you need only to convert the JSON data to an OJAI document (without saving to HPE Ezmeral Data Fabric Database), the `_id` field is not required. If the HPE Ezmeral Data Fabric Database table already contains a record with the same `_id` value, HPE Ezmeral Data Fabric Database replaces the record. Otherwise, it inserts a new record.

Just as you can load a JSON document into a Scala bean class (see [Creating an RDD of a Class](#)), you can save the RDD of Scala class objects in a HPE Ezmeral Data Fabric Database JSON table. `saveToMapRDB` can save any bean object as a JSON document by converting it to a JSON document.

Table Splits and `saveToMapRDB`

If the `createTable` parameter is set to `true`, `saveToMapRDB` can use the partition information from the RDD's lineage to create the splits for a new table:

Scala

```

sc.loadFromMapRDB("/tmp/
user_profiles").saveToMapRDB("/
userProfiles",

createTable = true)

```

Suppose `/tmp/user_profiles` has a table with five splits. `saveToMapRDB` uses this information to create the `/userProfiles` table with the same number and range of splits. You can also supply this information by using `MapRDBSpark.newPartitioner`:

Scala

```

sc.loadFromMapRDB("/tmp/
user_profiles").keyBy(doc =>
doc.get("_id"))
.repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String]
("/profiles"))
.saveToMapRDB("/userProfiles",
createTable = true)

```

For more information about partitioning, see [Using the Custom Partitioner with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark](#) on page 4546.

Saving an Apache Spark DataFrame to a HPE Ezmeral Data Fabric Database JSON Table

To save an Apache Spark DataFrame to a HPE Ezmeral Data Fabric Database, invoke the `saveToMapRDB` method on the `DataFrame` object (Scala). This returns a `DataFrameWriter` object, from which you can invoke the `saveToMapRDB` method. For Java and Python, invoke the `saveToMapRDB` method on the `MapRDBJavaSession` object or `SparkSession` object, respectively.

If a row with the same ID already exists, the `saveToMapRDB` method updates or overwrites that row. If you want an exception to be thrown in this case, you can use the [insertToMapRDB](#) method.

Scala

```
import com.mapr.db.spark.sql._

df.write.saveToMapRDB("/tmp/userInfo")
```

For EEP 4.1.0 and later, you can directly invoke the `saveToMapRDB` method on the `DataFrame` object:

```
def saveToMapRDB(tableName: String,
  idFieldPath : String = "_id",
  createTable: Boolean = false,
  bulkInsert: Boolean = false): Unit

import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

val df = spark.loadFromMapRDB("/tmp/
user_profiles")
df.saveToMapRDB(tableName,
createTable = true)
```

Java

For saving a `DataFrame (Dataset<Row>)`, apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](df: DataFrame[T],
  tableName: String, idFieldPath:
String, createTable: Boolean,
bulkInsert: Boolean): Unit

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");

maprSession.saveToMapRDB(ds, "/tmp/
userInfo");
```

Python

For saving a `DataFrame`, apply the following method on a `Dataframe`:

```
def saveToMapRDB(dataframe,
  table_name, id_field_path =
default_id_field, create_table =
False, bulk_insert = False)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")

sparkSession.saveToMapRDB(df,
table_name, create_table=True)
```

Inserting an Apache Spark `DataFrame` into a HPE Ezmeral Data Fabric Database JSON Table

Starting in the EEP 4.1.0 release, you can use the `insertToMapRDB` API to insert an Apache Spark DataFrame into a MapR Database JSON table in Python. The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

PySpark supports only `DataFrame(Dataset<Row>)`:

Python

```
sparkSession.insertToMapRDB(df,
                             tableName, idFieldPath, bulkInsert)
```

Using Alternate Write Modes for HPE Ezmeral Data Fabric Database OJAI Connector

You can use alternate write modes supported by MapR Database OJAI Connector for Apache Spark to save an Apache Spark DataFrame to a MapR Database JSON table.

Normally, the Apache Spark `DataFrameWriter` class supports the following write modes:

- Append
- Overwrite
- ErrorIfExists
- Ignore

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark returns an `OperationNotSupported` exception if you attempt to use one of these modes. The following example returns the error:

Scala

```
import org.apache.spark.sql.SaveMode
import com.mapr.db.spark.sql._

df.write.mode(SaveMode.Append).saveToMapRDB("/tmp/userInfo")
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following alternative modes:

Insert	Inserts the data into the HPE Ezmeral Data Fabric Database table. Throws a <code>DBException</code> if a row with same <code>_id</code> value already exists in the table.
Overwrite	Overwrites the data in the table with the current DataFrame data. This operation drops the table and creates a new table with the data.
ErrorIfExists	Returns an exception (<code>TableExistsException</code>) if the table already exists. Otherwise, creates the table and inserts the data.
Ignore	Ignores the data in the table if the table already exists. Otherwise, creates the table and inserts the data.
InsertOrReplace	Replaces the row with the row in the DataFrame, if a row with the same <code>_id</code> already exists in the table. Otherwise, inserts the new row.

You cannot specify these modes using the Apache Spark `SaveMode` method. Doing so results in the same `OperationNotSupported` exception noted earlier. To use these modes, you must call the `option` method on a `DataFrameWriter` object. The following example sets the `Insert` mode:

Scala

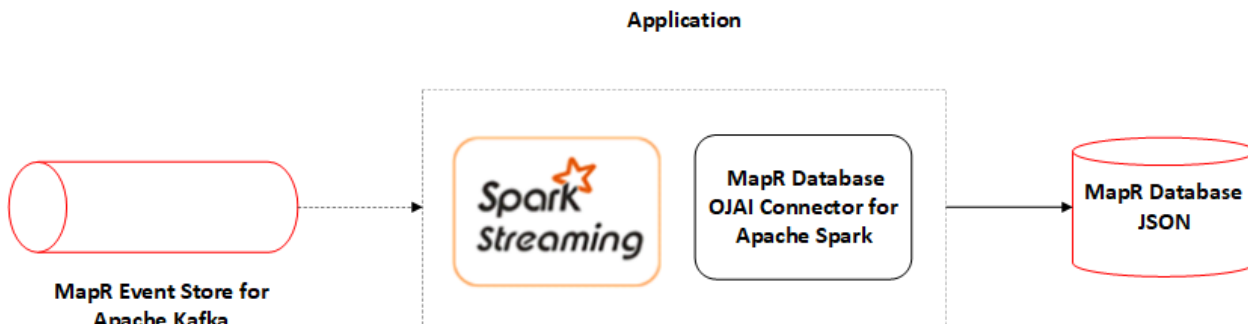

```
df.write.option("Operation",
"Insert").saveToMapRDB("/tmp/
usersInfo")
```

NOTE: The UPDATE mode for HPE Ezmeral Data Fabric Database OJAI Connector is not supported and it results in an `OperationNotSupported` exception.

Saving an Apache Spark DStream to a HPE Ezmeral Data Fabric Database JSON Table

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark enables you to use HPE Ezmeral Data Fabric Database as a sink for Apache Spark DStreams.

NOTE: Saving of Apache Spark DStream to HPE Ezmeral Data Fabric Database JSON table is currently only supported in Scala.

The following API saves a `DStream[OJAIDocument]` object to a HPE Ezmeral Data Fabric Database table:

Scala

```
def saveToMapRDB(tablename: String,
createTable: Boolean,
bulkInsert: Boolean,
idFieldPath: String): Unit
```

The parameters are as follows:

Parameter	Default	Description
tableName	Not applicable	The name of the HPE Ezmeral Data Fabric Database table to which you are saving the DStream.
createTable	false	Creates the table before saving the DStream. Note that if the table already exists and createTable is set to true, the API throws an exception.
idFieldPath	_id	Specifies the key to be used for the DStream.
bulkInsert	false	Loads a group of streams simultaneously. bulkInsert is similar to a bulk load in MapReduce.

NOTE: The only required parameter for this function is `tableName`. All the others are optional.

The following example creates a DStream object, converts it to a `DStream[OJAIDocument]` object, and then stores it in HPE Ezmeral Data Fabric Database:

Scala

```
val clicksStream: DStream[String] =
createKafkaStream(...)
```

```
clicksStream.map(MapRDBSpark.newDocument()  
).saveToMapRDB("/clicks",  
createTable=true)
```

 **NOTE:** You must use the `map(MapRDBSpark.newDocument())` API to convert the `DStream` object to a `DStream[OJAI Document]` object.

If `clicksStream` is a `DStream` of Strings, it can be saved to HPE Ezmeral Data Fabric Database using the `saveToMapRDB` API:

Scala

```
clicksStream.map(MapRDBSpark.newDocument(  
_)).saveToMapRDB("/clicks",  
createTable = true);
```

 **NOTE:** To use the `saveToMapRDB` API, you need to transform the `DStream` object to a `DStream[OJAI Document]` by using the Apache Spark Map API.

Saving an Apache Spark Dataset to a HPE Ezmeral Data Fabric Database JSON Table

Starting in the EEP 4.1.0 release, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to save a Dataset to a HPE Ezmeral Data Fabric Database table:

Scala

For saving a Dataset, apply the following method on a Spark object:

```
def saveToMapRDB(tableName: String,  
idFieldPath : String = "_id",  
createTable: Boolean =  
false, bulkInsert:Boolean = false):  
Unit  
  
import  
org.apache.spark.sql.Session  
import com.mapr.db.spark.sql._  
  
val ds = spark.loadFromMapRDB("/tmp/  
user_profiles")  
ds.saveToMapRDB(tableName,  
createTable = true)
```

Java

For saving a Dataset, apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](ds: Dataset[T],  
tableName: String, idFieldPath:  
String,  
createTable: Boolean,  
bulkInsert: Boolean): Unit  
  
import  
com.mapr.db.spark.sql.api.java.MapRDBJavaSession;  
import  
org.apache.spark.sql.Session;  
  
MapRDBJavaSession maprSession = new  
MapRDBJavaSession(spark);  
Dataset<Row> ds =
```

```
maprSession.loadFromMapRDB("/tmp/
user_profiles");
maprSession.saveToMapRDB(ds, true);
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert a Dataset into a HPE Ezmeral Data Fabric Database table:

Scala

```
import com.mapr.db.spark._

ds.insertToMapRDB(tableName,
idFieldPath, bulkInsert)
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.insertToMapRDB(ds,
tableName, idFieldPath, bulkInsert)
```

NOTE: The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

Word Count Example Using HPE Ezmeral Data Fabric Database OJAI Connector

Scala

Using Serialization with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark

In the context of the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, serialization refers to the methods that read and write objects into bytes. This section describes how to configure your application to use a more efficient serializer.

The Apache Spark cluster framework requires serialization to exchange objects between driver and cluster executors. This type of serialization has nothing to do with the way HPE Ezmeral Data Fabric Database serializes the objects onto the disk.

Because classes used in Spark transformations or actions must be serializable, classes created for the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark are serializable.

Spark uses Java serialization by default, but it can alternatively use Kyro Serialization. A new Kyro registrator is introduced so you can avoid using the default Java serialization. Kyro serialization provides better performance than Java serialization.

The following example shows how to set the new Kyro registrator in `sparkconf`:

Scala

```

new sparkconf()
  .set("spark.serializer",
"org.apache.spark.serializer.KryoSeria
lizer")
  .set("spark.kryo.registrator",

```

```
"com.mapr.db.spark.OJAIKryoRegistrar
")
```

A JSON document can use both complex and primitive value types. Java can serialize the primitive types, but for complex types (such as `Map`, `Array`, and `Binary`), you must use wrappers to achieve serialization. See [Working with Complex JSON Document Types](#) on page 4566 for details about these wrappers.

Time-related data types, such as `ODate`, `OInterval`, `OTime`, and `OTimeStamp`, use Java serialization by default. For efficiency, new serializers and comparators have been created for these data types.

Here are the new serializers and the type which each serializer applies:

Serializer	Type
<code>ODateSerializer</code>	<code>ODate</code> type
<code>OTimeSerializer</code>	<code>OTime</code>
<code>OTimeStampSerializer</code>	<code>OTimeStamp</code>
<code>OIntervalSerializer</code>	<code>OInterval</code>
<code>DBBinaryValueSerializer</code>	<code>ByteBuffer</code>

HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark

This section describes the three main interaction points between Spark and HBase APIs and provides examples for each interaction point.

The interaction points are:

Basic Spark	You can have an HBase Connection at any point in your Spark DAG.
Spark Streaming	You can have an HBase Connection at any point in your Spark Streaming application.
Spark Structured Streaming	Using Spark structured streaming to write data to a HPE Ezmeral Data Fabric Database binary table is currently not supported.
Spark Bulk Load	This option is currently not supported for HPE Ezmeral Data Fabric Database.
SparkSQL/DataFrames	You can write SparkSQL that draws on tables that are represented in HBase.

The following pages provide examples of each of these interaction points.

[Configuring the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark](#)

About this task

Use these steps to configure the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark:

Procedure

1. Verify that the `mapr-hbase` package is installed. For more information, refer to the [HBase release notes](#).
2. Copy the `HBASE_HOME/conf/hbase-site.xml` file to `SPARK_HOME/conf/`.
3. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf`:

```
spark.yarn.dist.files  SPARK_HOME/conf/hbase-site.xml
```

HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark Integration with Basic Spark
This page describes integration between Apache Spark and HBase APIs.

This section describes Spark integration with HBase APIs at the lowest and simplest levels. All other interaction points are built upon the concepts described here.

At the root of all integration with Spark and HBase APIs is the `HBaseContext`. The `HBaseContext` takes in HBase configurations and pushes them to the Spark executors. This allows you to have an `HBase Connection` per Spark executor in a static location.

HBaseContext Usage Example

This example shows how `HBaseContext` can be used to do a `foreachPartition` on an RDD in Scala:

```
val sc = new SparkContext("local", "test")
val config = new HbaseConfiguration()
...
val hbaseContext = new HBaseContext(sc, config)

rdd.hbaseForeachPartition(hbaseContext, (it, conn) => {
  val bufferedMutator = conn.getBufferedMutator(TableName.valueOf("/apps/
my_table"))
  it.foreach((putRecord) => {
    val put = new Put(putRecord._1)
    putRecord._2.foreach((putValue) =>
      put.addColumn(putValue._1,
        putValue._2, putValue._3))
    bufferedMutator.mutate(put)
  })
  bufferedMutator.flush()
  bufferedMutator.close()
})
```

Here is the same example implemented in Java:

```
JavaSparkContext jsc = new JavaSparkContext(sparkConf);

try {
  List<byte[]> list = new ArrayList<>();
  list.add(Bytes.toBytes("1"));
  ...
  list.add(Bytes.toBytes("5"));

  JavaRDD<byte[]> rdd = jsc.parallelize(list);
  Configuration conf = HBaseConfiguration.create();
  JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);

  hbaseContext.foreachPartition(
    rdd,
    new VoidFunction<Tuple2<Iterator<byte[]>, Connection>>() {
      public void call(Tuple2<Iterator<byte[]>, Connection> t) throws
Exception {
        Table table = t._2().getTable(TableName.valueOf(tableName));
        BufferedMutator mutator =
t._2().getBufferedMutator(TableName.valueOf(tableName));
        while (t._1().hasNext()) {
          byte[] b = t._1().next();
          Result r = table.get(new Get(b));
          if (r.getExists()) {
            mutator.mutate(new Put(b));
          }
        }
      }
    }

  mutator.flush();
  mutator.close();
  table.close();
}
```

```

    }
  });
} finally {
  jsc.stop();
}

```

All functionality between Spark and HBase Client is supported both in Scala and in Java, with the exception of SparkSQL, which supports any language that is supported by Spark. This section focuses on Scala examples.

The example here shows how to do a `foreachPartition` with a connection. A number of other Spark base functions are supported out of the box:

<code>bulkPut</code>	Enables massively parallel sending of puts to HBase.
<code>bulkDelete</code>	Enables massively parallel sending of deletes to HBase.
<code>bulkGet</code>	Enables massively parallel sending of gets to HBase to create a new RDD.
<code>mapPartition</code>	Enables the Spark Map function with a Connection object to allow full access to HBase.
<code>hBaseRDD</code>	Simplifies a distributed scan to create an RDD.

You can see examples of these commands in the [source code of the HBase-Spark Module](#).

HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark Integration with Spark Streaming

[Spark Streaming](#) is a micro-batching, stream-processing framework built on top of Spark. HBase APIs and Spark Streaming make great companions. When used alongside Spark Streaming, HBase APIs can serve as:

- A place to grab reference data or profile data on the fly.
- A place to store counts or aggregates in a way that supports the Spark Streaming promise of only once processing.

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark integration points with Spark Streaming are similar to its normal Spark integration points. You can use the following commands straight off a Spark Streaming DStream:

<code>bulkPut</code>	Enables massively parallel sending of puts to HBase APIs.
<code>bulkDelete</code>	Enables massively parallel sending of deletes to HBase APIs.
<code>bulkGet</code>	Enables massively parallel sending of gets to HBase APIs to create a new RDD.
<code>mapPartition</code>	Enables the Spark Map function with a Connection object to allow full access to HBase APIs.
<code>hBaseRDD</code>	Simplifies a distributed scan to create an RDD.

bulkPut Example with DStreams

The following example shows a `bulkPut` with DStreams. It is similar to the RDD bulk put.

NOTE: To invoke the `hbaseBulkPut` method, make sure you import the `HBaseDStreamFunctions` class.

```

import org.apache.hadoop.hbase.spark.HBaseDStreamFunctions._

val sc = new SparkContext("local", "test")
val config = new HBaseConfiguration()

```

```

val hbaseContext = new HBaseContext(sc, config)
val ssc = new StreamingContext(sc, Milliseconds(200))

val rdd1 = ...
val rdd2 = ...
val queue = mutable.Queue[
  RDD[(Array[Byte],
    Array[(Array[Byte],
      Array[Byte],
      Array[Byte])])]]()

queue += rdd1
queue += rdd2

val dStream = ssc.queueStream(queue)

dStream.hbaseBulkPut(
  hbaseContext,
  TableName.valueOf(tableName),
  (putRecord) => {
    val put = new Put(putRecord._1)
    putRecord._2.foreach((putValue) =>
      put.addColumn(putValue._1, putValue._2, putValue._3))
    put
  })

```

The `hbaseBulkPut` function has three inputs:

- The `hbaseContext` that carries the configuration broadcast information link to the HBase Connections in the executors.
- The table name of the table you are putting data into.
- A function that will convert a record in the DStream into an HBase `Put` object.

The code snippet above has been extracted from <https://github.com/mapr/hbase/blob/1.1.8-mapr-1703/hbase-spark/src/test/scala/org/apache/hadoop/hbase/spark/HBaseDStreamFunctionsSuite.scala>.

Bulk Loading Data into HBase with Spark

There are two options for bulk loading data into HBase with Spark:

NOTE: The bulk load operation is currently not supported for HPE Ezmeral Data Fabric Database.

Basic bulk load functionality

The basic bulk load functionality works for cases where your rows have millions of columns and cases where your columns are not consolidated.

Thin-record bulk load option

The thin-record bulk load option with Spark is designed for tables that have fewer than 10,000 columns per row. The advantage of this option is higher throughput and less overall load on the Spark shuffle operation.

Both implementations work more or less like the MapReduce bulk load process. A partitioner partitions the RowKeys based on region splits, and the RowKeys are sent to the reducers in order, so that HFiles can be written directly from the reduce phase.

In Spark terms, the bulk load is implemented around a `SparkrepartitionAndSortWithinPartitions` followed by a `Spark foreachPartition`. Here is an example of using the basic bulk load functionality:

Bulk Loading Example

NOTE: Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark._
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.util.Bytes._
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
import org.apache.hadoop.hbase.client.{HBaseAdmin, HConnectionManager}
val tableName = "table1"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
@transient val conf = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, conf)
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val rdd = sc.parallelize(Array(
  (toBytes("1"), (toBytes(columnFamily1), toBytes("a"),
toBytes("fool"))),
  (toBytes("3"), (toBytes(columnFamily1), toBytes("b"),
toBytes("foo2.b"))))
))
rdd.hbaseBulkLoad(hbaseContext,
  TableName.valueOf(tableName),
  t => {
    val rowKey = t._1
    val family: Array[Byte] = t._2._1
    val qualifier = t._2._2
    val value: Array[Byte] = t._2._3
    val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
    Seq((keyFamilyQualifier, value)).iterator
  },
  stagingFolder)
val connection = HConnectionManager.createConnection(conf)
val table = connection.getTable(TableName.valueOf(tableName))
val load = new LoadIncrementalHFiles(conf)
load.doBulkLoad(
  new Path(stagingFolder),
  connection.getAdmin,
  table,
  connection.getRegionLocator(TableName.valueOf(tableName)))
```

Required Parameters for Bulk Loading with Spark

The `hbaseBulkLoad` function takes three required parameters:

- The name of the table you intend to bulk load to.
- A function that converts a record in the RDD to a tuple key-value pair, with the tuple key being a `KeyFamilyQualifier` object and the value being the cell value. The `KeyFamilyQualifier` object holds the `RowKey`, `Column Family`, and `Column Qualifier`. The shuffle partitions on the `RowKey` but sorts by all three values.

- The temporary path for the HFile to be written out to. Following the Spark bulk load command, use the `HBase LoadIncrementalHFiles` object to load the newly created HFiles into HBase.

Additional Parameters for Bulk Loading with Spark

You can set the following attributes with additional parameter options on `hbaseBulkLoad`:

- Max file size of the HFiles
- A flag to exclude HFiles from compactions
- Column Family settings for compression, bloomType, blockSize, and dataBlockEncoding

The following example shows the use of additional parameters:

NOTE: Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{FamilyHFileWriteOptions,
HBaseContext, KeyFamilyQualifier}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, HConstants, TableName}
import org.apache.spark.sql.SparkSession
val tableName = "table2"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
val sc = spark.sparkContext
@transient val conf = HBaseConfiguration.create()
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val hbaseContext = new HBaseContext(sc, conf)
val rdd = sc.parallelize(Array(
  (Bytes.toBytes("1"),
  (Bytes.toBytes(columnFamily1),
  Bytes.toBytes("a"), Bytes.toBytes("foo1"))),
  (Bytes.toBytes("3"),
  (Bytes.toBytes(columnFamily1),
  Bytes.toBytes("b"),
  Bytes.toBytes("foo2.b")))))
val familyHBaseWriterOptions =
  new java.util.HashMap[Array[Byte], FamilyHFileWriteOptions]
val f1Options = new FamilyHFileWriteOptions("GZ", "ROW", 128, "PREFIX")
familyHBaseWriterOptions.put(Bytes.toBytes(columnFamily1), f1Options)
rdd.hbaseBulkLoad(hbaseContext,
  TableName.valueOf(tableName),
  t => {
    val rowKey = t._1
    val family:Array[Byte] = t._2._1
    val qualifier = t._2._2
    val value = t._2._3
    val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
    Seq((keyFamilyQualifier, value)).iterator
  },
  stagingFolder,
  familyHBaseWriterOptions,
```

```

        compactionExclude = false,
        HConstants.DEFAULT_MAX_FILE_SIZE)
    val connection = HConnectionManager.createConnection(conf)
    val table = connection.getTable(TableName.valueOf(tableName))
    val load = new LoadIncrementalHFiles(conf)
    load.doBulkLoad(new Path(stagingFolder),
        connection.getAdmin, table,
        connection.getRegionLocator(TableName.valueOf(tableName)))

```

Thin-Record Bulk Load Example

The following example shows how to call the thin-record bulk load implementation:

NOTE: Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```

import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{HBaseContext, _}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
val tableName = "table3"
    val stagingFolder = "/home/mapr"
    val columnFamily1 = "cf1"
    @transient val conf = HBaseConfiguration.create()
    val hbaseContext = new HBaseContext(sc, conf)
    conf.set(TableInputFormat.INPUT_TABLE, tableName)
    conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
    conf.setInt("hbase.zookeeper.property.clientPort", 5181)
    val rdd = sc.parallelize(Array(
        ("1", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("a"),
Bytes.toBytes("foo1"))),
        ("3", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("b"),
Bytes.toBytes("foo2.b")))))
    rdd.hbaseBulkLoadThinRows(hbaseContext,
        TableName.valueOf(tableName),
        t => {
            val rowKey = t._1
            val familyQualifiersValues = new FamiliesQualifiersValues
            val q = t._2
            val family:Array[Byte] = q.head
            val qualifier = q(1)
            val value:Array[Byte] = q(2)
            println(s"family: $family")
            println(s"qualifier: $qualifier")
            println(s"value: $value")
            familyQualifiersValues +=(family, qualifier, value)
            (new ByteArrayWrapper(Bytes.toBytes(rowKey)),
familyQualifiersValues)}, stagingFolder, new java.util.HashMap[Array[Byte],
FamilyHFileWriteOptions], compactionExclude = false, 20)
    val connection = HConnectionManager.createConnection(conf)
    val table = connection.getTable(TableName.valueOf(tableName))
    val load = new LoadIncrementalHFiles(conf)
    load.doBulkLoad(
        new Path(stagingFolder),
        connection.getAdmin,
        table,
        connection.getRegionLocator(TableName.valueOf(tableName)))

```

The big difference in using bulk load for thin rows is that the function returns a tuple with the first value being the RowKey and the second value being an object of `FamiliesQualifiersValues`. `FamiliesQualifiersValues` contains all the values for this row for all column families.

SparkSQL and DataFrames

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark leverages [DataSource API \(SPARK-3247\)](#) introduced in Spark-1.2.0. The connector bridges the gap between simple HBase KV store and complex relational SQL queries and enables users to perform complex data analytical work on top of HPE Ezmeral Data Fabric Database binary tables using Spark. HBase Dataframe is a standard Spark Dataframe, and is able to interact with any other data sources, such as Hive, Orc, Parquet, JSON, and others. The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark applies critical techniques such as partition pruning, column pruning, predicate pushdown and data locality.

To use the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark, you need to define the Catalog for the schema mapping between HPE Ezmeral Data Fabric Database binary tables and Spark tables, prepare the data and populate the HPE Ezmeral Data Fabric Database binary table, then load the HBase DataFrame. After that, users can do integrated query and access records in a HPE Ezmeral Data Fabric Database binary table with SQL query. The following examples illustrate the basic procedure.

Define Catalog Example

The `catalog` defines a mapping between HPE Ezmeral Data Fabric Database binary tables and Spark tables. There are two critical parts of this catalog. One is the rowkey definition. The other is the mapping between the table column in Spark and the column family and column qualifier in HPE Ezmeral Data Fabric Database binary table. The following example defines a schema for a HPE Ezmeral Data Fabric Database binary table with name as `my_table`, row key as `key` and a number of columns (`col1 - col8`). Note that the rowkey also has to be defined in details as a column (`col10`), which has a specific `cf` (`rowkey`).

```
def catalog = s"""{
  | "table": {"namespace": "default", "name": "/path_to/my_table"},
  | "rowkey": "key",
  | "columns": {
  |   | "col10": {"cf": "rowkey", "col": "key", "type": "string"},
  |   | "col11": {"cf": "cf1", "col": "col1", "type": "boolean"},
  |   | "col12": {"cf": "cf2", "col": "col2", "type": "double"},
  |   | "col13": {"cf": "cf3", "col": "col3", "type": "float"},
  |   | "col14": {"cf": "cf4", "col": "col4", "type": "int"},
  |   | "col15": {"cf": "cf5", "col": "col5", "type": "bigint"},
  |   | "col16": {"cf": "cf6", "col": "col6", "type": "smallint"},
  |   | "col17": {"cf": "cf7", "col": "col7", "type": "string"},
  |   | "col18": {"cf": "cf8", "col": "col8", "type": "tinyint"}
  | }
  |}""" .stripMargin
```

Save the DataFrame Example

Data prepared by the user is a local Scala collection that has 256 `HBaseRecord` objects. The `sc.parallelize(data)` function distributes data to form an RDD. `toDF` returns a `DataFrame`. `writefunction` returns a `DataFrameWriter` used to write the `DataFrame` to external storage systems (e.g. HPE Ezmeral Data Fabric Database here). Given a `DataFrame` with a specified schema catalog, the `save` function creates a HPE Ezmeral Data Fabric Database binary table with five (5) regions and saves the `DataFrame` inside.

```
case class HBaseRecord(
  col0: String,
  col1: Boolean,
  col2: Double,
  col3: Float,
```

```

col4: Int,
col5: Long,
col6: Short,
col7: String,
col8: Byte)

object HBaseRecord
{
  def apply(i: Int, t: String): HBaseRecord = {
    val s = s""row${"%03d".format(i)}""
    HBaseRecord(s,
      i % 2 == 0,
      i.toDouble,
      i.toFloat,
      i,
      i.toLong,
      i.toShort,
      s"String$i: $t",
      i.toByte)
  }
}

val data = (0 to 255).map { i => HBaseRecord(i, "extra")}

sc.parallelize(data).toDF.write.options(Map(
  HBaseTableCatalog.tableCatalog -> catalog,
  HBaseTableCatalog.newTable -> "5" )
).format("org.apache.hadoop.hbase.spark")
.save()

```

Load the DataFrame Example

In the `withCatalog` function, `sqlContext` is a variable of `SQLContext`, which is the entry point for working with structured data (rows and columns) in Spark. `read` returns a `DataFrameReader` that can be used to read data in a `DataFrame`. The `option` function adds input options for the underlying data source to the `DataFrameReader`. The `format` function specifies the input data source format for the `DataFrameReader`. The `load()` function loads input as a `DataFrame`. The data frame `df` returned by the `withCatalog` function can be used to access the HPE Ezmeral Data Fabric Database binary table, as shown in the Language Integrated Query and SQL Query examples.

```

def withCatalog(cat: String): DataFrame = {
  sqlContext
  .read
  .options(Map(HBaseTableCatalog.tableCatalog->cat))
  .format("org.apache.hadoop.hbase.spark")
  .load()
}
val df = withCatalog(catalog)

```

Language Integrated Query Example

`DataFrame` can do various operations, such as `join`, `sort`, `select`, `filter`, `orderBy`, and so on. In the following example, `df.filter` filters rows using the given SQL expression. `select` selects a set of columns: `col0`, `col1` and `col4`.

```

val s = df.filter(($"col0" <= "row050" && $"col0" > "row040") ||
  $"col0" === "row005" ||
  $"col0" <= "row005")

```

```
.select("col0", "col1", "col4")
s.show
```

SQL Query Example

`registerTempTable` registers `df` `DataFrame` as a temporary table using the table name `table1`. The lifetime of this temporary table is tied to the `SQLContext` that was used to create `df`. `sqlContext.sqlfunction` allows the user to execute SQL queries.

```
df.registerTempTable("table1")
sqlContext.sql("select count(col1) from table1").show
```

Query with Different Timestamps

In `HBaseSparkConf`, you can set four parameters related to timestamp:

- `TIMESTAMP`
- `MIN_TIMESTAMP`
- `MAX_TIMESTAMP`
- `MAX_VERSIONS`

With `MIN_TIMESTAMP` and `MAX_TIMESTAMP`, you can query records with different timestamps or time ranges. In the meantime, use a concrete value instead of `tsSpecified` and `oldMs` in the following examples. The first example shows how to load `df` `DataFrame` with different timestamps. `tsSpecified` is specified by the user. `HBaseTableCatalog` defines the HBase and Relation relation schema. `writeCatalog` defines the catalog for the schema mapping.

```
val df = sqlContext.read
  .options(Map(
    HBaseTableCatalog.tableCatalog -> writeCatalog,
    HBaseSparkConf.TIMESTAMP -> tsSpecified.toString)
  ).format("org.apache.hadoop.hbase.spark")
  .load()
```

The following example shows how to load `df` `DataFrame` with different time ranges. `oldMs` is specified by the user.

```
val df = sqlContext.read
  .options(Map(
    HBaseTableCatalog.tableCatalog -> writeCatalog,
    HBaseSparkConf.MIN_TIMESTAMP -> "0",
    HBaseSparkConf.MAX_TIMESTAMP -> oldMs.toString)
  ).format("org.apache.hadoop.hbase.spark")
  .load()
```

After loading `df` `DataFrame`, users can query data.

```
df.registerTempTable("table")
sqlContext.sql("select count(col1) from table").show
```

Native Avro Support

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark supports different data formats such as Avro, JSON, and others. The following use case shows how Spark supports Avro. You can persist the Avro record into HPE Ezmeral Data Fabric Database binary tables directly. Internally, the Avro schema is converted to a native Spark Catalyst data type automatically. Note that both key-value parts in a HPE Ezmeral Data Fabric Database binary table can be defined in Avro format.

1. Define the catalog for schema mapping. `catalog` is a schema for a HPE Ezmeral Data Fabric Database binary table named `Avrotable`, a row key as `key`, and one column `col1`. The rowkey also has to be defined in details as a column (`col0`), which has a specific `cf` (`rowkey`).

```
def catalog = s"""{
  "table": {"namespace": "default", "name": "/path_to/
  avro_table"},
  "rowkey": "key",
  "columns": {
    "col0": {"cf": "rowkey", "col": "key",
    "type": "string"},
    "col1": {"cf": "cf1", "col": "col1", "type": "binary"}
  }
}""".stripMargin
```

2. Prepare the data. `schemaString` is defined first. Then it is parsed to get `avroSchema`. `avroSchema` is used to generate `AvroHBaseRecord`. data prepared by users is a local Scala collection that has 256 `AvroHBaseRecord` objects.

```
object AvroHBaseRecord {
  val schemaString =
    s"""{"namespace": "example.avro",
        "type": "record",      "name": "User",
        "fields": [
          {"name": "name", "type": "string"},
          {"name": "favorite_number", "type": ["int", "null"]},
          {"name": "favorite_color", "type": ["string", "null"]},
          {"name": "favorite_array", "type": {"type": "array",
"items": "string"}},
          {"name": "favorite_map", "type": {"type": "map",
"values": "int"}}
        ]}""".stripMargin

  val avroSchema: Schema = {
    val p = new Schema.Parser
    p.parse(schemaString)
  }

  def apply(i: Int): AvroHBaseRecord = {
    val user = new GenericData.Record(avroSchema);
    user.put("name", s"name${"%03d".format(i)}")
    user.put("favorite_number", i)
    user.put("favorite_color", s"color${"%03d".format(i)}")
    val favoriteArray = new GenericData.Array[String](
      2,
      avroSchema.getField("favorite_array").schema()
    )
    favoriteArray.add(s"number${i}")
    favoriteArray.add(s"number${i+1}")
    user.put("favorite_array", favoriteArray)
    import collection.JavaConverters._
    val favoriteMap = Map[String, Int](("key1" -> i), ("key2" ->
(i+1))).asJava
    user.put("favorite_map", favoriteMap)
    val avroByte = AvroSedes.serialize(user, avroSchema)
    AvroHBaseRecord(s"name${"%03d".format(i)}", avroByte)
  }
}

val data = (0 to 255).map { i =>
  AvroHBaseRecord(i)
}
```

3. Save the DataFrame. Given a data frame with the specified schema catalog, the following example creates a HPE Ezmeral Data Fabric Database binary table with five (5) regions and saves the data frame inside.

```
sc.parallelize(data).toDF.write.options(
  Map(
    HBaseTableCatalog.tableCatalog -> catalog,
    HBaseTableCatalog.newTable -> "5")
).format("org.apache.spark.sql.execution.datasources.hbase")
.save()
```

4. Load the DataFrame. In the `withCatalog` function, `read` returns a `DataFrameReader` that can be used to read data in as a `DataFrame`. The `option` function adds input options for the underlying data source to the `DataFrameReader`. There are two options: one is to set `avroSchema` as `AvroHBaseRecord.schemaString`. The other option is to set `HBaseTableCatalog.tableCatalog` as `avroCatalog`. The `load()` function loads input in as a `DataFrame`. The data frame `df` returned by the `withCatalog` function can be used to access the HPE Ezmeral Data Fabric Database binary table.

```
def avroCatalog = s"""{
  | "table": {"namespace": "default", "name": "avrotable"},
  | "rowkey": "key",
  | "columns": {
  |   | "col0": {"cf": "rowkey", "col": "key", "type": "string"},
  |   | "col1": {"cf": "cf1", "col": "col1", "avro": "avroSchema"}
  | }
  |}""" .stripMargin

def withCatalog(cat: String): DataFrame = {
  sqlContext
    .read
    .options(Map(
      "avroSchema" -> AvroHBaseRecord.schemaString,
      HBaseTableCatalog.tableCatalog -> avroCatalog
    ))
    .format("org.apache.spark.sql.execution.datasources.hbase")
    .load()
}

val df = withCatalog(catalog)
```

5. Query data using SQL. After loading `df` `DataFrame`, you can query data. `registerTempTable` registers `df` `DataFrame` as a temporary table using the table name `avrotable`. The `sqlContext.sql` function allows you to execute SQL queries.

```
df.registerTempTable("avrotable")
val c = sqlContext.sql("select count(1) from avrotable")
```

Integrating Spark

This section includes the following topics about configuring Spark to work with other ecosystem components.

Integrate Spark-SQL (Spark 2.3.1 and later) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 2.3.0 or later users.

Prerequisites

NOTE: For Spark 2.2.1 and 2.3.1 versions, use the 4.0.0 avro version of `com.databricks:spark-avro_2.11`.

About this task

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

Procedure

1. Download the Avro 1.7.7 JAR file to the Spark `jars` (`opt/mapr/spark/spark-<version>/jars`) directory.

You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>

2. Add the following properties in `spark-defaults.conf`:

```
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
spark.executor.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
```

Integrate Spark-SQL (Spark 1.6.1) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 1.6.1 or earlier users.

About this task

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

Procedure

1. Download the Avro 1.7.7 JAR file to the Spark lib (`opt/mapr/spark/spark-<version>/lib`) directory.

You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>

2. Use one of the following methods to add the Avro 1.7.7 JAR to the classpath:

- Prepend the Avro 1.7.7 JAR file to the `spark.executor.extraClassPath` and `spark.driver.extraClassPath` in the `spark-defaults.conf` (`/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf`) file:

```
spark.executor.extraClassPath /opt/mapr/spark/
spark-<spark_version>/lib/avro-1.7.7.jar:<rest_of_path>
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/lib/
avro-1.7.7.jar:<rest_of_path>
```

- Specify the Avro 1.7.7 JAR files with command line arguments on the spark shell:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell \
--packages com.databricks:spark-avro_2.10:2.0.1 \
--driver-class-path /opt/mapr/spark/spark-<version>/lib/avro-1.7.7.jar \
--conf spark.executor.extraClassPath=/opt/mapr/spark/
spark-<version>/lib/avro-1.7.7.jar --master <master-url>
```

Integrate Spark with HBase

Integrate Spark with HBase or HPE Ezmeral Data Fabric Database when you want to run Spark jobs on HBase or HPE Ezmeral Data Fabric Database tables.

About this task

If you installed Spark with the MapR Installer, these steps are not required.

Procedure

1. Configure the HBase version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hbase_versions=<version>
```

The HBase version depends on the current EEP and MapR version that you are running.

2. If you want to create HBase tables with Spark, add the following property to `hbase-site.xml`:

```
<property>
hbase.table.sanity.checks</name>
<value>>false</value>
</property>
```

3. On each Spark node, copy the `hbase-site.xml` to the `{SPARK_HOME}/conf/` directory.

TIP: Starting in the EEP 7.0.0 release, you do not have to complete step 3. Running `configure.sh` copies the `hbase-site.xml` file to the Spark directory automatically.

4. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
spark.yarn.dist.files SPARK_HOME/conf/hbase-site.xml
```

5. To verify the integration, complete the following steps:

- a) Create an HBase or HPE Ezmeral Data Fabric Database table:

```
create '<table_name>' , '<column_family>'
```

- b) Run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
/opt/mapr/spark/spark-<spark_version>/bin/spark-submit --master
<master> [--deploy-mode <deploy-mode>] --class
org.apache.hadoop.hbase.spark.example.rdd.HBaseBulkPutExample /opt/
mapr/hbase/hbase-<hbase_version>/lib/
hbase-spark-<hbase_version>-mapr.jar <table_name> <column_family>
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn`, or `local` (without `deploy-mode`). The `deploy-mode` is either `client` or `cluster`.

- c) Check the data in the HBase or MapR-DB table:

```
hbase(main):001:0> scan '<table_name>'
```

Integrate Spark-SQL (Spark 2.0.1 and later) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 2.0.1 or later users.

About this task

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

NOTE: If you installed Spark with the MapR Installer, the following steps are not required.

Procedure

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration. Do not create a symbolic link instead of copying the file. You may need to edit the file with settings that are specific to the Spark Thrift server.
2. Add 644 permission to the `hive-site.xml` using the following command:

```
sudo chmod 644 /opt/mapr/spark/spark-<sparkVersion>/conf/hive-site.xml
```

3. If Hive is configured on Tez (not on MR), you must remove the Tez property from the Spark conf directory `hive-site.xml`. Delete this entry:

```
<property>
  <name>hive.execution.engine</name>
  <value>tez</value>
</property>
```

4. If Hive is configured on PAM, set "`hive.metastore.sasl.enabled = true`" in the `hive-site.xml` located in the Spark conf directory.
5. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements
<code>spark.yarn.dist.files</code>	For Spark on YARN, specify the location of the <code>hive-site.xml</code> file: <pre>/opt/mapr/spark/spark-<spark-version>/conf/hive-site.xml</pre>
<code>spark.sql.hive.metastore.version</code>	Specify the Hive version that you are using.  NOTE: If you are using Hive Metastore 2.1, set the version to 1.2.1.

6. Depending on whether you plan to run with impersonation, perform one of the following:
 - Configure user impersonation. See [Hive User Impersonation](#) for the steps to configure impersonation in the Spark Thrift server.
 - Set `hive.server2.enable.doAs` to `false` in the `hive-site.xml` file.
7. To verify the integration, run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
<spark-home>/bin/run-example --master <master> [--deploy-mode <deploy-mode>] sql.hive.SparkHiveExample
```

The master URL for the cluster is either `spark://<host>:7077` or `yarn`. The `deploy-mode` is either `client` or `cluster`.

What to do next

 **NOTE:** The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

 **NOTE:** If you plan to access Hive tables that store data in HPE Ezmeral Data Fabric Database, you need to copy the Hive HBase handler jar into the Spark jars directory. For example:

```
cp /opt/mapr/hive/hive-2.1/lib/hive-hbase-handler-2.1.1-mapr-1707.jar /opt/mapr/spark/spark-2.1.0/jars/
```

Integrate Spark-SQL (Spark 1.6.1) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 1.6.1 or earlier users.

About this task

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

 **NOTE:** If you installed Spark with the MapR Installer, the following steps are not required.

Procedure

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration.
2. Configure the Hive version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hive_versions=<version>
```

3. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements
spark.yarn.dist.files	<p>Option 1: For Spark on YARN, specify the location of the hive-site.xml and the datanucleus JARs:</p> <pre>/opt/mapr/hive/hive-<hive-version>/conf/hive-site.xml,/opt/mapr/hive/<version>/lib/datanucleus-api-jdo-<version>.jar,/opt/mapr/hive/<version>/lib/datanucleus-core-<version>.jar,/opt/mapr/hive/hive-1.2/lib/datanucleus-rdbms-<version>.jar</pre> <p>Option 2: For Spark on YARN, store hive-site.xml and datanucleus JARs on file system, and use the following syntax:</p> <pre>maprfs:///<path to hive-site.xml>,maprfs:///<path to datanucleus jar files></pre>
spark.sql.hive.metastore.version	Specify the Hive version that you are using. For example, for Hive 1.2.x, set the value to 1.2.0.
spark.sql.hive.metastore.jars	<p>Specify the classpath to JARs for Hive, Hive dependencies, and Hadoop. These files must be available on the node from which you submit Spark jobs:</p> <pre>/opt/mapr/hadoop/hadoop-<hadoop-version>/etc/hadoop:/opt/mapr/hadoop/hadoop-<hadoop-version>/share/hadoop/common/lib/*:<rest of hadoop classpath>:/opt/mapr/hive/hive-<version>/lib/accumulo-core-<version>.jar:/opt/mapr/hive/hive-<version>/lib/hive-contrib-<version>.jar:<rest of hive classpath></pre> <p>For example, when you run with Hive 1.2, you can set the following classpath:</p> <pre>/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/*:/opt/mapr/hadoop/.hadoop-2.7.0/share/hadoop/mapreduce/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/yarn/*:/opt/mapr/hive/hive-1.2/lib/accumulo-core-1.6.0.jar:/opt/mapr/hive/hive-1.2/lib/hive-contrib-1.2.0-mapr-1607.jar:/opt/mapr/hive/hive-1.2/lib/*</pre> <p>For more information, see the Apache Spark documentation.</p>

4. To verify the integration, run the following command as the mapr user or as a user that mapr impersonates:

```
MASTER=<master-url> <spark-home>/bin/run-example sql.hive.HiveFromSpark
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn-client`, or `yarn-cluster`.

What to do next

NOTE: The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

Integrate Spark with HPE Ezmeral Data Fabric Streams

Integrate Spark with MapR Streams to enable Spark to query HPE Ezmeral Data Fabric Streams for new messages at a given interval, process any new messages that are available, and also publish messages into HPE Ezmeral Data Fabric Streams.

You can use Spark to access HPE Ezmeral Data Fabric Streams through Spark's receiver-less, direct approach.

For more information, see the [Apache Spark documentation](#).

NOTE: Before you integrate Spark with HPE Ezmeral Data Fabric Streams, verify that the Streams Client is installed on all Spark nodes. For more information, see the [Installing Core and Ecosystem Components](#) on page 91.

Configure Spark 2.2.1 and later to Consume HPE Ezmeral Data Fabric Streams Messages

Using the Kafka 0.9 API, you can configure a Spark application to query HPE Ezmeral Data Fabric Streams for new messages at a given interval. This information is for Spark 2.2.1 and later users.

About this task

Procedure

1. Install the [MapR core Kafka package](#), if you have not already done so.
2. Copy the Kafka client jar into the Spark jars directory as shown below:

```
cp /opt/mapr/lib/kafka-clients-<version>.jar SPARK_HOME/jars
```

3. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-0-9_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

NOTE: If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`).

4. Consider the following when you write the Spark application:
 - a) Verify that it meets the following requirements:
 - Imports and use classes from `org.apache.spark.streaming.kafka09`. The following code snippet imports three classes.

```
import org.apache.spark.streaming.kafka09.{ConsumerStrategies,
KafkaUtils, LocationStrategies}
```

- Defines key and value deserializers in the kafkaParams map.

```
val kafkaParams = Map[String, String](
  ConsumerConfig.GROUP_ID_CONFIG -> groupId,
  ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.AUTO_OFFSET_RESET_CONFIG -> offsetReset)
```

- Does not configure a broker address or Zookeeper as these are not required for HPE Ezmeral Data Fabric Streams.
- b) Optionally, define a value for `spark.streaming.kafka.consumer.poll.ms` in the Spark configuration.

NOTE: You can configure the poll timeout using Spark option `spark.streaming.kafka.consumer.poll.ms`. If you do not configure `spark.streaming.kafka.consumer.poll.ms`, the `spark.network.timeout` property is used. If `spark.network.timeout` is empty, the default is 120 seconds.

```
val sparkConf = new SparkConf()
  .setAppName("v09DirectKafkaWordCount")
  .set("spark.streaming.kafka.consumer.poll.ms", pollTimeout)
```

Example:

<https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/V09DirectKafkaWordCount.scala> is a sample consumer program.

The `KafkaUtils.createDirectStream` method creates an input stream to read HPE Ezmeral Data Fabric Streams messages. The `ConsumerStrategies.Subscribe` method creates the consumer strategy that will limit the set of topics the stream subscribes to. This is derived from the `topics` parameter passed into the program. Using `LocationStrategies.PreferConsistent` will distribute partitions evenly across available executors.

```
val consumerStrategy = ConsumerStrategies.Subscribe[String, String]
  (topicsSet, kafkaParams)
val messages = KafkaUtils.createDirectStream[String, String](
  ssc, LocationStrategies.PreferConsistent, consumerStrategy)
```

Configure Spark to Produce HPE Ezmeral Data Fabric Streams Messages

Using the Kafka 0.9 API, you can configure a Spark application to produce MapR Streams messages.

Procedure

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

NOTE: If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`).

- When you write the Spark program, import and use classes from `org.apache.spark.streaming.kafka.producer._` and `org.apache.spark.streaming.dstream`.

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter.

```
val producerConf = new ProducerConf(bootstrapServers =
  kafkaBrokers.split(", ").toList)
  .withKeySerializer("org.apache.kafka.common.serialization.ByteArraySerializer")
  .withValueSerializer("org.apache.kafka.common.serialization.StringSerializer")

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
  defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

The `org.apache.kafka.common.serialization.ByteArraySerializer` and `org.apache.kafka.common.serialization.StringSerializer` properties are used by default, and in case you do not want to use another serializer, `withKeySerializer` and `withValueSerializer` methods are not necessary.

Example

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

Integrate Spark with R

You integrate Spark with R when you want to run R programs as Spark jobs.

About this task

Procedure

- On each node that will submit Spark jobs, install R 3.2.2 or greater:

- On Ubuntu:

```
apt-get install r-base-dev
```

- On CentOS/RedHat:

```
yum install R
```

For more information about installing R, see the [R documentation](#).

- To verify the integration, run the following commands as the `mapr` user or as a user that `mapr` impersonates:

a) Start Spark R:

- On Spark 2.0.1, 2.1.0, and later:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master>
[--deploy-mode <deploy-mode>]
```

- On Spark 1.6.1:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master-url>
```

b) Run the following command to create a DataFrame using sample data:

On Spark 1.6.1:

```
people <- read.df(sqlContext, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

On Spark 2.0.1, 2.1.0, and later:

```
people <- read.df(spark, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

c) Run the following command to display the data from the DataFrame that you just created:

```
head(people)
```

Integrate Spark with Kafka

From EEP-5.0.0, Spark can be integrated with Kafka-1.0. You can configure a Spark application to produce Kafka messages.

About this task

NOTE: Starting from EEP-8.0.0, HPE Ezmeral Data Fabric does not support `spark-streaming-kafka-producer`. To learn about Kafka integration on Apache Spark 3.1.2 and later in HPE Ezmeral Data Fabric, see [Structured Streaming + Kafka Integration Guide \(Kafka broker version 0.10.0 or higher\)](#).

Procedure

- Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

2. When you write the Spark program, import and use classes from:

```
org.apache.spark.streaming.kafka.producer._
org.apache.spark.streaming.dstream.
```

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

3. In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter:

```
val producerConf = new ProducerConf(
  bootstrapServers = kafkaBrokers.split(",").toList)

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
  defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

Example

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

Spark JDBC and ODBC Drivers

MapR provides JDBC and ODBC drivers so you can write SQL queries that access the Apache Spark data-processing engine. This section describes how to download the drivers, and install and configure them.

You can download the Spark JDBC driver from https://package.ezmeral.hpe.com/tools/MapR-JDBC/MapR_Spark/ and the Spark ODBC driver from https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Spark/.

After downloading the driver, refer to the documentation at [Spark JDBC Driver](#) to install and configure the JDBC driver and [Spark ODBC Driver](#) for the ODBC driver. A copy of the documentation also is available in each download package. The following table describes the driver versions available for various EEP releases:

	EEP version	Driver version	Driver link	Documentation link
JDBC version	EEP 6.0.0+	2.6.3	Spark JDBC Driver for version 2.6.3	Spark JDBC Documentation for version 2.6.3
	EEP 3.0.1+	1.1.8	Spark JDBC Driver for version 1.1.8	Spark JDBC Documentation for version 1.1.8
ODBC version	EEP 6.0.0+	2.6.1	Spark ODBC Driver for version 2.6.1	Spark ODBC Documentation for version 2.6.1
	EEP 2.0.2+	1.2.5	Spark ODBC Driver for version 1.2.5	Spark ODBC Documentation for version 1.2.5

NOTE: When connecting to the Spark Thrift Server using `beeline` and the JDBC driver, you might encounter the following error:

```
"Unsupported transaction isolation level: 4"
```

To avoid this error, pass the `isolation` parameter to `beeline` as follows:

```
bin/beeline --isolation=default
```

Spark API Changes

This topic describes the public API changes that occurred for specific Spark versions.

Spark 2.3.1 API Changes

EEP 6.0.0 supports Spark version 2.3.1.

For more information about Spark 2.3.1, see the [Spark 2.3.1-1808 \(EEP 6.0.0\) Release Notes](#) on page 7481 and the [Spark 2.3.1 API Documentation](#).

For a complete list of all new and changed APIs, refer to the [open source documentation](#).

Spark 2.1.0 API Changes

This topic describes the public API changes that occurred between Apache Spark 2.0.1 and Spark 2.1.0.

For more information about Spark 2.1.0, see the [Spark Release Notes](#) and the [Spark 2.1.0 API Documentation](#).

New API

- The `DataTypes` API is now mostly stable. Please see `InterfaceStability` annotations for the classes you need.
- Add the `from_json` and `to_json` functions to SQL.
- `StructType` now accepts Python Dictionaries.
- New ML algorithms have been added for Spark R.
- `SparkContext.addFile` is now supported for SparkR.
- SparkR now supports multinomial logistics regression.
- MLlib supports MLR in DataFrames, LSH.
- MLlib model loading is now backward-compatible with Spark 1.6.

Changed API

- Parquet-MR is bumped to 1.8.1.
- `spark.sql.warehouse.dir` now needs to be set before `SparkSession` creation and is shared between multiple `SparkSessions`.
- Values generated by non-deterministic functions will not change after `coalesce` or `union`.
- The default `Locale` for `DateFormat/NumberFormat` is now `Locale.US`.
- Function `SIZE` returns -1 when its input parameter is null.

Spark 2.0.1-1703 API Changes

This release does not introduce any changes to public Spark API apart from Structured Streaming, which is not supported by the MapR platform.

Spark 2.0.1-1611 API Changes

This topic describes the public API changes that occurred between Apache Spark 1.6.1 and Spark 2.0.1.

Removed Methods

The following items have been removed from [Apache Spark 2.0.1](#):

- Bagel (the Spark implementation of Google Pregel)
- Most of the deprecated methods from Spark 1.x, including:

Category	Subcategory	Instead of this removed API...	Use...
GraphX		mapReduceTriplets	aggregateMessages
		runSVDPlusPlus	run
		GraphKryoRegistrar	
SQL	DataType	DataType.fromCaseClassString	DataType.fromJson
	DecimalType	DecimalType()	DecimalType(precision, scale) precision explicitly
		DecimalType(Option[PrecisionInfo])	DecimalType(precision scale)
		PrecisionInfo	DecimalType(precision, scale)
		precisionInfo	precision and scale
		Unlimited	(No longer supported)
	Column	Column.in()	isin()
	DataFrame	toSchemaRDD	toDF
		createJDBCTable	write.jdbc()
		saveAsParquetFile	write.parquet()
saveAsTable		write.saveAsTable()	
save		write.save()	
insertInto		write.mode(SaveMode.Append).s	
DataframeReader		DataFrameReader.load(path)	option("path", path).load()
Functions	cumeDist	cume_dist	
	denseRank	dense_rank	
	percentRank	percent_rank	
	rowNumber	row_number	
	inputFileName	input_file_name	
	isNaN	isnan	
	sparkPartitionId	spark_partition_id	
	callUDF	udf	
Core	SparkContext	Constructors no longer take preferredNodeLocationData param	

Category	Subcategory	Instead of this removed API...	Use...
		tachyonFolderName	externalBlockStoreFolderName
		initLocalProperties, clearFiles, clearJars	(No longer needed)
		runJob method no longer takes allowLocal param	
		defaultMinSplits	defaultMinPartitions
		[Double, Int, Long, Float]AccumulatorParam	implicit objects from AccumulatorParam
		rddTo[Pair, Async, Sequence, Ordered]RDDFunctions	implicit functions from RDD
		[double, numeric]RDDToDoubleRDDFunctions	implicit functions from RDD
		intToIntWritable, longToLongWritable, floatToFloatWritable, doubleToDoubleWritable, boolToBoolWritable, bytesToBytesWritable, stringToText	implicit functions from WritableFactories
		[int, long, double, float, boolean, bytes, string, writable]WritableConverter	implicit functions from WritableConverters
	TaskContext	runningLocally	isRunningLocally
		addOnCompleteCallback	addTaskCompletionListener
		attemptId	attemptNumber
	JavaRDDLike	splits	partitions
		toArray	collect
	JavaSparkContext	defaultMinSplits	defaultMinPartitions
		clearJars, clearFiles	(No longer needed)
	PairRDDFunctions	PairRDDFunctions.reduceByKeyToDriver	reduceByKeyLocally
	RDD	mapPartitionsWithContext	TaskContext.get
		mapPartitionsWithSplit	mapPartitionsWithIndex
		mapWith	mapPartitionsWithIndex
		flatMapWith	mapPartitionsWithIndex and flatMap
		foreachWith	mapPartitionsWithIndex and foreach
		filterWith	mapPartitionsWithIndex and filter
		toArray	collect
	TaskInfo	TaskInfo.attempt	TaskInfo.attemptNumber
	Guava Optional	Guava Optional	org.apache.spark.api.java.Optional
	Vector	Vector, VectorSuite	
Configuration options and params		--name	

Category	Subcategory	Instead of this removed API...	Use...
		<code>--driver-memory</code>	<code>spark.driver.memory</code>
		<code>--driver-cores</code>	<code>spark.driver.cores</code>
		<code>--executor-memory</code>	<code>spark.executor.memory</code>
		<code>--executor-cores</code>	<code>spark.executor.cores</code>
		<code>--queue</code>	<code>spark.yarn.queue</code>
		<code>--files</code>	<code>spark.yarn.dist.files</code>
		<code>--archives</code>	<code>spark.yarn.dist.archives</code>
		<code>--addJars</code>	<code>spark.yarn.dist.jars</code>
		<code>--py-files</code>	<code>spark.submit.pyFiles</code>

Note also the following deprecated configuration options and parameters:

- Methods from Python `DataFrame` that returned RDD have been moved to `dataframe.rdd`. For example, `df.map` is now `df.rdd.map`.
- Some streaming connectors (Twitter, Akka, MQTT, and ZeroMQ) have been removed.
- `org.apache.spark.shuffle.hash.HashShuffleManager` no longer exists. `SortShuffleManager` is the default since Spark 1.2.
- `DataFrame` is no longer a class. It is a subtype of `DataSet`.

Behavior Changes

Spark 2.0.1 implements the following behavior changes:

- Spark 2.0.1 uses Scala 2.11 instead of 2.10.
- Floating literals in SQL are now parsed as decimal type instead of double type.
- The Kryo version is now 3.0.
- Jersey version is now 2.
- Java RDD `flatMap` and `mapPartitions` functions now require functions that return Java iterator instead of `Iterable`.
- Java RDD `countByKey` and `countApproxDistinctByKey` now return `Map[K => Long]` instead of `Map[K => Object]`.
- When writing Parquet files, the summary files are no longer written (set `parquet.enable.summary-metadata` to `true` to re-enable).
- Lots were changed in MLLib. Follow the [Apache Spark Migration Guide](#).
- `SparkContext.emptyRDD` now returns RDD instead of `EmptyRDD`.
- Spark Standalone Master no longer serves the jobs history.
- [org.apache.spark.api.java.JavaPairRDD](#) methods were changed:
 - `countByKey` and `countApproxDistinctByKey` now return `java.lang.Long` instead of `scala.Long`.

- `sampleByKey` and `sampleByKeyExact` now return `java.lang.Double` instead of `scala.Double`.
- The Old Application History format that created folders for each application has been removed.
- `org.apache.spark.Logging` is now private. You can use `slf4j` directly instead.

Other Deprecated Items

- Java 7 is now deprecated.
- Python 2.6 is now deprecated.
- `TaskContext.isRunningLocally` now is always false, as there is no more local execution of `yarn-client` and `yarn-cluster` as masters. Use `--master yarn` and `--deploy-mode client/cluster`.
- Instead of `HiveContext`, use `SparkSession.builder.enableHiveSupport`.
- Instead of `SQLContext`, use `SparkSession.builder`.
- Some methods related to `Accumulators`, `ShuffleWriteMetrics`, `SparkLoop`, `DataSet`, and `SQLContext` are now deprecated. You will see warnings in your application logs if you use them.

Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

Related Links

Spark streaming is integrated with HPE Ezmeral Data Fabric Streams for Apache Kafka.

- [MapR Event Store For Apache Kafka Clients and Tools](#)

Prerequisites for Using Structured Streaming in Spark

To deploy a structured streaming application in Spark, you must create a MapR Streams topic and install a Kafka client on all nodes in your cluster.

Creating a MapR Streams Topic

Procedure

- Create a MapR Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

Installing a Kafka Client

Procedure

- Install a `kafka-client` on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

Using Structured Streaming to Create a Word Count Application

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

*Using Apache Kafka***Example****Scala**

```

val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCo
unt")
    .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.server
s", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS
STRING)")
    .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
    .outputMode("complete")
    .format("console")
    .option("checkpointLocation",
checkpointLocation)
    .start()

query.awaitTermination()

```

Java

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructured
KafkaWordCount")
    .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap
.servers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("

```

```

   )).iterator(),
    Encoders.STRING()).groupBy("value").count();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
            .outputMode("complete")
            .format("console")
            .start();

query.awaitTermination();

```

Python

```

spark = SparkSession\
    .builder\
    .appName("StructuredKafkaWordCount")\
    .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
    .readStream\
    .format("kafka")\
    .option("kafka.bootstrap.servers", bootstrapServers)\
    .option(subscribeType,
topics)\
    .load()\
    .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row
explode(
    split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
    .writeStream\
    .outputMode('complete')\
    .format('console')\
    .start()

query.awaitTermination()

```

Using MapR Event Store for Apache Kafka

Example

For MapR Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val dfl = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
  "maprdemo:9092").option("subscribe", topic).option("group.id",
  "testgroup").option("startingOffsets",
  "earliest").option("failOnDataLoss",
  false).option("maxOffsetsPerTrigger", 1000).load()
```

Writing a Structured Spark Stream to HPE Ezmeral Data Fabric Database JSON Table

The example in this section writes a structured stream in Spark to HPE Ezmeral Data Fabric Database JSON table.

Example

To write a structured Spark stream to HPE Ezmeral Data Fabric Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

Scala

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
  .writeStream
  .format(MapRDBSourceConfig.Format)
  .option(MapRDBSourceConfig.TablePath
Option, "/table/path")
  .option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
  .option(MapRDBSourceConfig.CreateTab
leOption, true)
  .option(MapRDBSourceConfig.BulkModeO
ption, true)
  .option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
  .outputMode("append")
}
```

Java

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
```

```

org.apache.spark.sql.streaming.DataStreamReader;
import
org.apache.spark.sql.streaming.DataStreamWriter;
import
org.apache.spark.sql.streaming.StreamingQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
    return df.selectExpr("CAST(value
AS STRING) as _id")
        .writeStream()
        .format(MapRDBSourceConfig
.Format())
        .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
        .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
        .option(MapRDBSourceConfig
.CreateTableOption(), true)
        .option(MapRDBSourceConfig
.BulkModeOption(), true)
        .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
        .outputMode("append");
}

```

Python

```

from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
    return df.selectExpr("CAST(value AS
STRING) as _id") \
        .writeStream \
        .format("com.mapr.db.spark.
streaming") \
        .option("checkpointLocation
", checkpoint_dir) \
        .option("tablePath",
table_path) \
        .option("idFieldPath",
"value") \
        .option("createTable",
True) \
        .option("bulkMode", True) \
        .option("sampleSize", 1000)

```

Writing a Spark Stream Word Count Application to HPE Ezmeral Data Fabric Database

The example in this section writes a Spark stream word count application to HPE Ezmeral Data Fabric Database.

Example

Scala

```

val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCou
nt")
    .getOrCreate()

```

```

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS
STRING)")
    .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
    .format(MapRDBSourceConfig.Format)
    .option(MapRDBSourceConfig.Table
PathOption, resultTable)
    .option(MapRDBSourceConfig.Creat
eTableOption, true)
    .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
    .outputMode("complete")
    .start()

query.awaitTermination()

```

Java

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructuredKaf
kaWordCount")
    .getOrCreate();

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap.s
ervers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("

```

```

    ").iterator(),
    Encoders.STRING()).groupBy("value").count();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
    .format(MapRDBSourceConfig
.Format())
    .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
    .option(MapRDBSourceConfig
.CreateTableOption(), true)
    .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
    .outputMode("complete");
    .start();

query.awaitTermination();

```

Python

```

spark = SparkSession\
    .builder\
    .appName("StructuredKafkaWo
rdCount")\
    .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
    .readStream\
    .format("kafka")\
    .option("kafka.bootstrap.ser
vers", bootstrapServers)\
    .option(subscribeType,
topics)\
    .load()\
    .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
    split(lines.value, ' ')
    ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
    .writeStream\
    .format("com.mapr.db.spa
rk.streaming") \
    .option("tablePath",
table_path) \

```

```

True) \
        .option("createTable",
"value") \
        .option("idFieldPath",
        .outputMode('complete')\
        .start()

query.awaitTermination()

```

PAM Authentication for Spark

Spark supports PAM authentication on secure MapR clusters.

In EEP-5.0.0, PAM authentication and encryption is enabled by default for all Spark Web UIs. After running `configure.sh`, if the cluster is secure and Spark is installed, Spark will be configured using PAM.

NOTE: Spark PAM is available in Spark-2.2.1 from EEP-5.0 and in Spark-2.1.0 from EEP-4.1.1.

See [Configuring PAM](#) on page 1780 for information on how PAM works with MapR.

Read or Write LZO Compressed Data for Spark

This topic provides details for reading or writing LZO compressed data for Spark.

Procedure

1. Install the LZO library:

```
sudo yum install lzo-devel lzo
```

2. Clone `hadoop-lzo` and build it:

```
[mapr@node1 ~]$ git clone https://github.com/twitter/hadoop-lzo
[mapr@node1 ~]$ cd hadoop-lzo
[mapr@node1 hadoop-lzo]$ mvn package
```

3. Copy the jar file to hadoop classpath:

```
[mapr@node1 hadoop-lzo]$ sudo
cp target/hadoop-lzo-0.4.21-SNAPSHOT.jar /opt/mapr/hadoop/hadoop-2.7.0/
share/hadoop/yarn/lib/
```

4. Add two LZO compression codes to `core-site.xml`:

```
property: io.compression.codecs
codecs:
com.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec/
```

It will look like this:

```
<property>
  <name>io.compression.codecs</name>

  <value>org.apache.hadoop.io.compress.DefaultCodec,org.apache.hadoop.io.co
mpress.GzipCodec,org.apache.hadoop.io.compress.BZip2Codec,org.apache.hado
op.io.compress.DeflateCodec,org.apache.hadoop.io.compress.SnappyCodec,com
.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec</
value>
</property>

<property>
  <name>io.compression.codec.lzo.class</name>
  <value>com.hadoop.compression.lzo.LzoCodec</value>
</property>
```

5. Run Spark and read LZO compressed data:

```
[mapr@node1 spark]$ ./bin/spark-shell --master yarn
spark.read.csv("/user/mapr/LzoCompressedCsv").show
```

6. Write LZO compressed data with Spark:

```
scala>
df.write.option("codec", "com.hadoop.compression.lzo.LzopCodec").csv("csv1
")

[mapr@node1 spark]$ hadoop fs -ls /user/mapr/csv1
Found 2 items
-rwxr-xr-x  3 mapr mapr          0 2017-12-15 12:42 /user/mapr/csv1/_
_SUCCESS
-rwxr-xr-x  3 mapr mapr  493366 2017-12-15 12:42 /user/mapr/csv1/p
art-00000-256a95a9-eb9c-4048-b7ce-c95dfbef54d7.csv.lzo
```

Ports Used by Spark

To run a Spark job from a client node, ephemeral ports should be opened in the cluster for the client from which you are running the Spark job.

If you do not want to open all the ephemeral ports, you can use the configuration parameter to specify the range of ports.

To set ports to special values, use the `spark.driver.port`, `spark.blockManager.port`, and `spark.port.maxRetries` properties. The `spark.port.maxRetries` property is 16 by default.

For example, if you need to open port 200 for `spark.blockManager.port` from 40000, set `spark.blockManager.port = 40000` and `spark.port.maxRetries = 200`.

For a list of Web UIs ports dynamically used when starting spark contexts, see the [open source documentation](#).

The default port numbers that need to be opened on the firewall behind the client and MapR cluster nodes for Spark jobs to operate in YARN client, YARN cluster, and standalone modes are as follows:

Service	Port Number
Spark Standalone Master (RPC)	7077
Spark Standalone Master (Web UI)	8580, 8980*
Spark Standalone Worker	8581, 8981*
Spark Thrift Server	2304
Spark History Server	18080,18480*
Spark External Shuffle Service (if yarn shuffle service is enabled)	7337
CLDB	7222
ZooKeeper	5181
Nodes running ResourceManager	8032
MapR Filesystem Server	5660, 5692

* refers to ports for secure clusters

ACL Configuration for Spark

Starting in the EEP 6.0 release, the ACL configuration for Spark is disabled by default.

If you are authorized by PAM, you will have access to all Spark UIs. For the Spark History Server, you can only see the logs of your own Spark jobs if PAM is enabled (regardless of ACL being enabled).

Starting in Spark-2.4.4.0, MapR Spark ACLs behave like Apache Spark ACLs. With this change, all users can log in to the Spark History Server UI and see the full list of applications. Only an application owner or the users specified in `spark.ui.view.acls` or `history.ui.admin.acls` can see application details. Users specified in `history.ui.admin.acls` can see the details for all applications.

By default on a secure cluster:

```
spark.acls.enable false
spark.admin.acls mapr
spark.admin.acls.groups mapr
spark.ui.view.acls mapruser1
```

Other Example:

```
spark.acls.enable true - ACL is enabled and restricted access to Spark
master and thriftserver UIs for other users.
spark.admin.acls mapr - Administrator or "sudoer" of ACL access.
spark.admin.acls.groups mapr - Group of administrators.
spark.ui.view.acls mapruser1 - user who can be logged in to Spark master
and thriftserver UIs.
```

Sqoop

IMPORTANT: This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Apache Sqoop™ is a tool designed to efficiently transfer bulk data between Apache Hadoop and structured datastores, such as relational databases.

This documentation provides information for using Sqoop, but does not duplicate the Apache Sqoop™ documentation on the [Apache Sqoop website](#).

The following table describes the feature of Sqoop1:

Feature	Sqoop1
Specialized connectors for all major RDBMS	Available.
Data transfer from RDBMS to Hive	Done automatically.
Data transfer from Hive to RDBMS	Must be done manually in two stages: <ol style="list-style-type: none"> 1. Extract data from Hive into file system, as a text file or as an Avro file. 2. Export the output of step 1 to an RDBMS using Sqoop.
Integrated Kerberos security	Supported.
Password encryption	Not supported.

Sqoop1

 **IMPORTANT:** This component is deprecated. Hewlett Packard Enterprise recommends using an alternate product. Deprecated components are either in maintenance or have reached the end of their maintenance lifecycle. For more information, see [Discontinued Ecosystem Components](#) on page 6598.

Sqoop transfers data between the file system and relational databases. You can use Sqoop to transfer data from a relational database management system (RDBMS), such as MySQL or Oracle, into the file system and use MapReduce on the transferred data. Sqoop can export this transformed data back into an RDBMS.

The Maven repository contains JAR files for Sqoop that you can download and use for your application:

Version	Core	EEP	Maven Repository Locations
Sqoop 1.4.7	6.2.x	7.1.0	1.4.7.0-mapr-710
		7.0.1	1.4.7-mapr-701/
		7.0.0	1.4.7-mapr-mep-7.x-2009/

For more information about Sqoop, see the [Apache Sqoop 1.4.7 Documentation](#).

YARN

YARN is a resource-management and scheduling framework that distributes resource-management and job-management duties. YARN assigns the resource-management and job-management duties as follows:

- ResourceManager: manages cluster resources and tracks resource usage and node health.
- ApplicationMaster: a framework-specific process that negotiates resources for a single application (a single job or a directed acyclic graph of jobs), which runs in the first *container* allocated for the application.
- A YARN component called the HistoryServer archives job metrics and metadata. Status on completed applications is available via REST APIs.

The ResourceManager allocates resources among all the applications running the cluster. The ResourceManager includes a pluggable scheduler, which is responsible for allocating resources according to the resource requirements of the running applications. Current MapReduce schedulers, including the Capacity Scheduler and the Fair Scheduler, can be plugged into the YARN scheduler directly.

Label-based scheduling provides job placement control on a multi-tenant Hadoop cluster. Administrators can control exactly which nodes are chosen to run jobs submitted by different users and groups. An administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When users run jobs, they can place them on specified nodes on a per-job basis (using a job label) or on a per-queue level (using a queue label).

The ResourceManager caches the mapping file, and checks every two minutes (the default monitoring period) for updates. If the file has been modified, the ResourceManager updates the labels for all active ApplicationMasters immediately.

Each application runs an ApplicationMaster to negotiate resources from the ResourceManager. The ApplicationMaster works with the NodeManagers to execute and monitor tasks. The duties of the ApplicationMaster are divided as follows:

- NodeManager: One instance runs on each node, to manage that node's resources.
- Container: An abstraction representing a unit of resources on a node.

The NodeManager provides containers to an application. The ResourceManager and the NodeManager provide the system for distributed management of applications and resources.

ResourceManager

Describes the role of the ResourceManager.

The ResourceManager is mainly concerned with arbitrating available resources in the cluster among competing applications, with the goal of maximum cluster utilization. The ResourceManager includes a pluggable scheduler called the YarnScheduler, which allows different policies for managing constraints such as capacity, fairness, and service level agreements.

The ResourceManager manages resources as follows:

- Each NodeManager takes instructions from the ResourceManager, reporting and handling containers on a single node
- Each ApplicationMaster requests resources from the ResourceManager, then works with containers provided by NodeManagers

The ResourceManager communicates with application clients via an interface called the ClientService. A client can submit or terminate an application and gain information about the scheduling queue or cluster statistics through the ClientService.

Administrative requests are served by a separate interface called the AdminService, through which operators can get updated information about cluster operation.

Behind the scenes, the ResourceTrackerService receives node heartbeats from the NodeManager to track new or decommissioned nodes. The NMLivelinessMonitor and NodesListManager keep an updated status of which nodes are healthy so that the scheduler and the ResourceTrackerService can allocate work appropriately.

A component called the ApplicationMasterService manages ApplicationMasters on all nodes, keeping the scheduler informed. A component called the AMLivelinessMonitor keeps a list of ApplicationMasters and their last heartbeat times, in order to let the ResourceManager know what applications are healthy on the cluster. Any ApplicationMaster that does not heartbeat within a certain interval is marked as dead and re-scheduled to run on a new container.

At the core of the ResourceManager is an interface called the ApplicationsManager, which maintains a list of applications that have been submitted, are running, or are completed. The ApplicationsManager accepts

job submissions, negotiates the first container for an application (in which the ApplicationMaster will run) and restarts the ApplicationMaster if it fails.

The ResourceManager and NodeManagers communicate via heartbeats.

Configure the ResourceManager for high availability so that the failure of the ResourceManager service is a not single point of failure for the cluster. High availability of the ResourceManager is configured by default when you run `configure.sh` without specifying the `-RM` parameter.

ApplicationMaster

Describes the role of the ApplicationMaster.

The ApplicationMaster is an instance of a framework-specific library that negotiates resources from the ResourceManager and works with the NodeManager to execute and monitor the granted resources (bundled as containers) for a given application. An application can be a process or set of processes, a service, or a description of work.

The ApplicationMaster is run in a container like any other application. The ApplicationsManager, part of the ResourceManager, negotiates for the container in which an application's ApplicationMaster runs when the application is scheduled by the YarnScheduler.

While an application is running, the ApplicationMaster manages the following:

- Application life cycle
- Dynamic adjustments to resource consumption
- Execution flow
- Faults
- Providing status and metrics

The ApplicationMaster is designed to support a specific framework, and can be written in any language since its communication with the NodeManagers and the ResourceManager is accomplished using extensible communication protocols. The ApplicationMaster can be customized to extend the framework or run any other code. For this reason, the ApplicationMaster is not considered trustworthy, and is not run as a trusted service.

An ApplicationMaster typically requests resources on multiple nodes to complete a job by sending the ResourceManager requests that include locality preferences and attributes of the containers. When the ResourceManager is able to allocate a resource to the ApplicationMaster, it generates a lease that the ApplicationMaster pulls on a subsequent heartbeat. A security token associated with the lease guarantees its authenticity when the ApplicationManager presents the lease to the NodeManager to gain access to the container.

The Application Master heartbeats to the ResourceManager to communicate its changing resource needs, and to let the ResourceManager know it is still alive. In response, the ResourceManager can return a lease on additional containers on other nodes, or cancel the lease on some containers. The ApplicationMaster can then adjust its execution strategy to fit the increase or decrease in available resources. When cluster resources become scarce, the ResourceManager can also request that the ApplicationMaster relinquish some resources. The ApplicationMaster can move work to other running containers in order to give up resources gracefully.

Containers

A YARN container is a result of a successful resource allocation, meaning that the ResourceManager has granted an application a lease to use a specific set of resources in certain amounts on a specific node. The ApplicationMaster presents the lease to the NodeManager on the node where the container has been allocated, thereby gaining access to the resources.

To launch the container, the ApplicationMaster must provide a container launch context (CLC) that includes the following information:

- Environment variables
- Dependencies (local resources such as data files or shared objects needed prior to launch)
- Security tokens
- The command necessary to create the process the application plans to launch

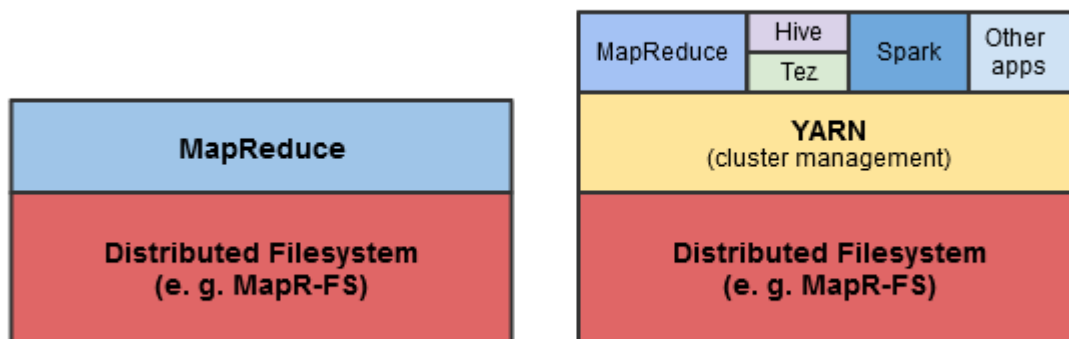

The CLC makes it possible for the ApplicationMaster to use containers to run a variety of different kinds of work, from simple shell scripts to applications to virtual machines.

MapReduce Version 2

Provides an overview of how MapReduce works.

YARN dynamically allocates resources for applications as they execute. The MapReduce version 1 (MRv1) has been rewritten to run as an application on top of YARN; this new version is called MapReduce version 2.0 (MRv2).

Figure 2. A comparison between MapReduce 1.0 and MapReduce 2.0

The main advancement in YARN architecture is the separation of resource management and job management, which were both handled by the same process (the JobTracker) in Hadoop 1.x. Cluster resources and job scheduling are managed by the ResourceManager, while resource negotiation and job monitoring are managed by an ApplicationMaster for each application running on the cluster. In MapReduce, each node advertises a relatively fixed number of map slots and reduce slots. This can lead to resource under-utilization, for example, when there is a heavy reduce load and map slots are available, because the map slots cannot accept reduce tasks (and vice versa).

YARN generalizes resource management for use by new engines and frameworks, allowing resources to be allocated and reallocated for different concurrent applications sharing a cluster. Existing MapReduce applications can run on YARN without any changes. At the same time, because MapReduce is now merely another application on YARN, MapReduce is free to evolve independently of the resource management infrastructure.

How Applications Work in YARN

Describes the data flow during application execution in YARN.

The following diagram and steps describe how data flows during application execution in YARN.

The following steps summarize execution of the application:

1. A client submits an application to the YARN ResourceManager, including the information required for the Container Life Cycle (CLC).
2. The ApplicationsManager (in the ResourceManager) negotiates a container and bootstraps the ApplicationMaster instance for the application.
3. The ApplicationMaster registers with the ResourceManager and requests containers.
4. The ApplicationMaster communicates with NodeManagers to launch the containers it has been granted, specifying the CLC for each container.
5. The ApplicationMaster manages application execution. During execution, the application provides progress and status information to the ApplicationMaster. The client can monitor the application's status by querying the ResourceManager or by communicating directly with the ApplicationMaster.
6. The ApplicationMaster reports completion of the application to the ResourceManager.
7. The ApplicationMaster deregisters with the ResourceManager, which then cleans up the ApplicationMaster container.

Direct Shuffle on YARN

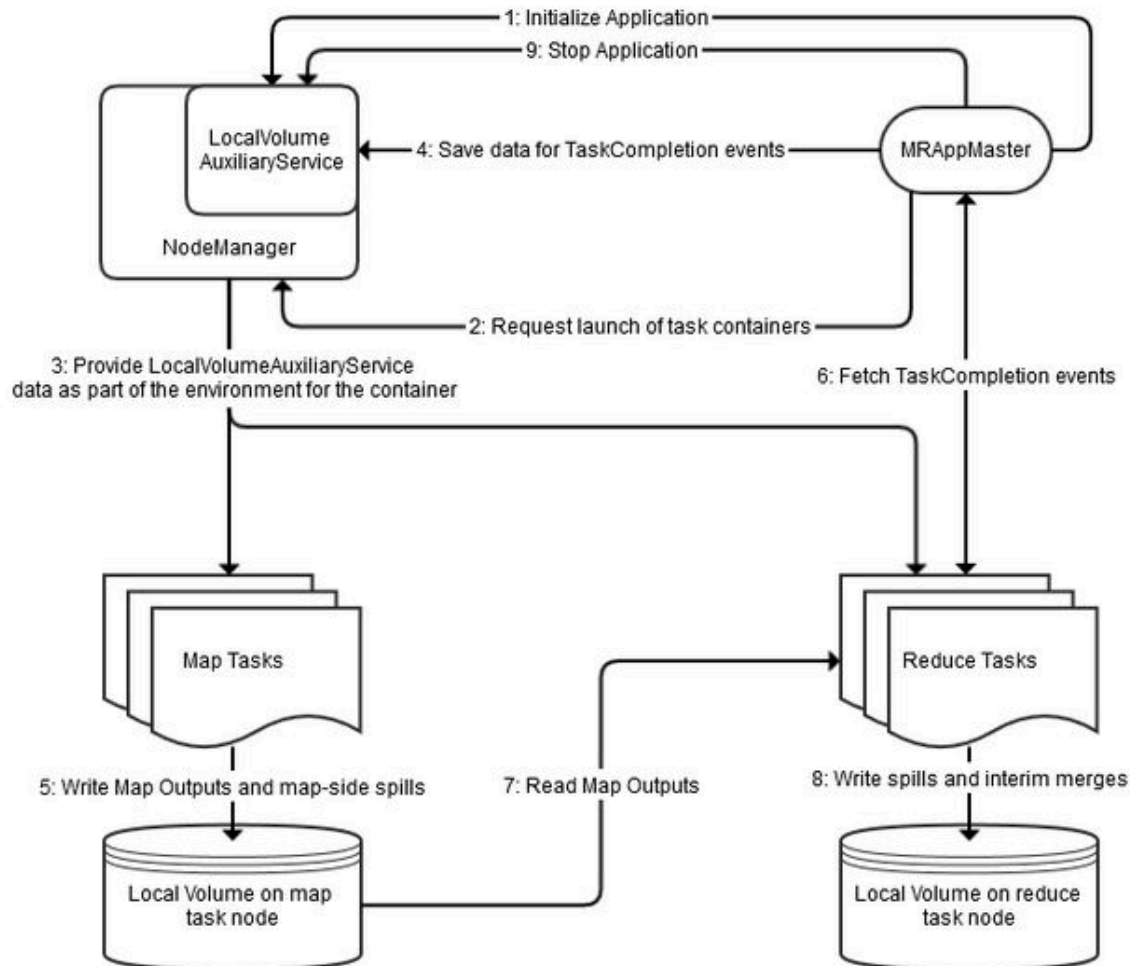

Explains the shuffle phase of a MapReduce application.

Overview of Direct Shuffle

During the shuffle phase of a MapReduce application, HPE Ezmeral Data Fabric writes to a file system volume limited by its topology to the local node instead of writing intermediate data to local disks controlled by the operating system. This improves performance and reduces demand on local disk space while making the output available cluster-wide.

Direct Shuffle is the default shuffle mechanism for HPE Ezmeral Data Fabric. However, you can modify the `yarn-site.xml` and `mapred-site.xml` configuration files to enable Apache Shuffle for MapReduce applications. See [Apache Shuffle on YARN](#).

The `LocalVolumeAuxiliaryService` runs in the `NodeManager` process. The `LocalVolumeAuxiliaryService` manages the local volume on each node and cleans up shuffle data after a MapReduce application has finished executing.

1. The MRAppMaster service initializes the application by calling `initializeApplication()` on the `LocalVolumeAuxiliaryService`.
2. The MRAppMaster service requests task containers from the Resource Manager. The Resource Manager sends the MRAppMaster information that MRAppMaster uses to request containers from the NodeManager.
3. The NodeManager on each node launches containers using information about the node's local volume from the `LocalVolumeAuxiliaryService`.
4. Data from map tasks is saved in MRAppMaster for later use in TaskCompletion events, which are requested by reduce tasks.
5. As map tasks complete, map outputs and map-side spills are written to the local volumes on the map task nodes, generating Task Completion events.

6. ReduceTasks fetch Task Completion events from the Application Manager. The task Completion events include information on the location of map output data, enabling reduce tasks to copy data from MapOutput locations.
7. Reduce tasks read the map output information.
8. Spills and interim merges are written to local volumes on the reduce task nodes.
9. MRAppMaster calls `stopApplication()` on the `LocalVolumeAuxiliaryService` to clean up data on the local volume.

Configuration for Direct Shuffle

The default YARN parameters for Direct Shuffle are as follows:

```
<property>
  <name>yarn.nodemanager.aux-services</name>
  <value>mapreduce_shuffle,mapr_direct_shuffle</value>
  <description>shuffle service that needs to be set for Map Reduce to
run</description>
</property>
<property>
  <name>yarn.nodemanager.aux-services.mapr_direct_shuffle.class</name>
  <value>org.apache.hadoop.mapred.LocalVolumeAuxService</value>
</property>
```

The default mapred parameters for Direct Shuffle are as follows:

```
<property>
  <name>mapreduce.job.shuffle.provider.services</name>
  <value>mapr_direct_shuffle</value>
</property>
<property>
  <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
  <value>org.apache.hadoop.mapreduce.task.reduce.DirectShuffle</value>
</property>
<property>
  <name>mapreduce.job.map.output.collector.class</name>
  <value>org.apache.hadoop.mapred.MapRFsOutputBuffer</value>
</property>
<property>
  <name>mapred.ifile.outputstream</name>
  <value>org.apache.hadoop.mapred.MapRIFileOutputStream</value>
</property>
<property>
  <name>mapred.ifile.inputstream</name>
  <value>org.apache.hadoop.mapred.MapRIFileInputStream</value>
</property>
<property>
  <name>mapred.local.mapoutput</name>
  <value>>false</value>
</property>
<property>
  <name>mapreduce.task.local.output.class</name>
  <value>org.apache.hadoop.mapred.MapRFsOutputFile</value>
</property>
```

Apache Shuffle on YARN

You can disable Direct Shuffle and enable Apache Shuffle by modifying the configuration options in the `yarn-site.xml` and `mapred-site.xml` files. This page describes how to configure Apache Shuffle for MapReduce applications.

The shuffling phase in Hadoop is the process of transferring mappers intermediate output to the reducers. Direct shuffle increases the load on file system disks. You can enable the Apache Shuffle to reduce the load on file system disks.

Configuration for Apache Shuffle

Add the following property to `yarn-site.xml` file:

```
<property>
  <name>yarn.nodemanager.aux-services</name>
  <value>mapreduce_shuffle</value>
</property>
```

Add the following properties to `mapred-site.xml` file:

```
<property>
  <name>mapreduce.job.shuffle.provider.services</name>
  <value>mapreduce_shuffle</value>
</property>
<property>
  <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
  <value>org.apache.hadoop.mapreduce.task.reduce.Shuffle</value>
</property>
<property>
  <name>mapreduce.job.map.output.collector.class</name>
  <value>org.apache.hadoop.mapred.MapTask$MapOutputBuffer</value>
</property>
<property>
  <name>mapred.ifile.outputstream</name>
  <value>org.apache.hadoop.mapred.FileOutputStream</value>
</property>
<property>
  <name>mapred.ifile.inputstream</name>
  <value>org.apache.hadoop.mapred.FileInputStream</value>
</property>
<property>
  <name>mapred.local.mapoutput</name>
  <value>>true</value>
</property>
<property>
  <name>mapreduce.task.local.output.class</name>
  <value>org.apache.hadoop.mapred.YarnOutputFiles</value>
</property>
```

Logging Options on YARN

Describes the logging options that are available on YARN.

For YARN applications, there are various logging options to choose from based on the data-fabric version and the types of applications that you run. In 4.0.2 and later versions, you have the following logging options:

- For MapReduce version 2 (MRv2) applications, the default logging option is to log files on the local filesystem. However, central logging and YARN log aggregation are also available.
- For non-MapReduce applications, the default logging option is to log files on the local filesystem. However, YARN log aggregation is also available.

Centralized Logging for MRv2

Centralized logging provides an application-centric view of all the log files generated by NodeManager nodes throughout the cluster. It enables users to gain

a complete picture of application execution by having all the logs available in a single directory, without having to navigate from node to node.

The MapReduce program generates three types of log output:

- Standard output stream: captured in the `stdout` file
- Standard error stream: captured in the `stderr` file
- Log4j logs: captured in the `syslog` file

Centralized logs are available cluster-wide as they are written to the following local volume on the data-fabric filesystem: /

```
var/mapr/local/<NodeManager node>/
logs/yarn/userlogs
```

Since the log files are stored in a local volume directory that is associated with each NodeManager node, you run the `maprcli job linklogs` command to create symbolic links for all the logs in a single directory. You can then use tools such as `grep` and `awk` to analyze them from an NFS mount point. You can also view the entire set of logs for a particular application using the HistoryServer UI.

The YARN log aggregation option aggregates logs from the local filesystem and moves log files for completed applications from the local filesystem to the data-fabric filesystem. This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

YARN Log Aggregation

Support for ADLS

Starting with MapR 6.1, you can use Azure Data Lake Store (ADLS) as a data source or destination for all applications.

Prerequisites for Using ADLS

Setting up Azure Data Lake Store (ADLS) on the Azure portal enables you to access ADLS from any application.

- Create an account on the [Azure portal](#).
- Create an Azure Data Lake Store ([get started with Azure Data Lake Storage](#)).

Authenticating ADLS Account

To access data stored in Azure Data Lake Store (ADLS), you must first authenticate your ADLS account using your ADLS credentials.

Procedure

1. Obtain the following properties from your Azure application:

- `dfs.adls.oauth2.access.token.provider.type`
ClientCredential, Refresh Tokens, or Client Keys to obtain the authentication type.

- `dfs.adls.oauth2.client.id`

Create an Azure Active Directory application and get your application ID and authentication key.

- `dfs.adls.oauth2.refresh.url`

Navigate to Azure Active Directory and click on `Endpoints`. Use the `OAUTH 2.0 TOKEN ENDPOINT` value.

- `dfs.adls.oauth2.credential`

Obtain the access token key value from `App Registrations` in your Azure account.

2. Add the properties obtained in step 1 to the `core-site.xml` file:

```
<!--ADL-->
<property>
  <name>dfs.adls.oauth2.access.token.provider.type</name>
  <value>ClientCredential</value>
</property>

<property>
  <name>dfs.adls.oauth2.client.id</name>
  <value>f377fab9-c0a3-4531-alc9-77345105</value>
</property>

<property>
  <name>dfs.adls.oauth2.refresh.url</name>
  <value>https://login.microsoftonline.com/25735fb/oauth2/token</value>
</property>

<property>
  <name>dfs.adls.oauth2.credential</name>
  <value>WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/d2z2CGiw=</value>
</property>
```

NOTE: The `core-site.xml` file can be overwritten using the command line. You can also specify these properties at runtime. The syntax for overwriting ADLS properties at runtime using the command line is as follows:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
-Ddfs.adls.oauth2.access.token.provider.type=ClientCredential
-Ddfs.adls.oauth2.client.id=f377fab9-c0a3-4531-alc9-77345105
-Ddfs.adls.oauth2.refresh.url=https://login.microsoftonline.com/
25735fb/oauth2/token
-Ddfs.adls.oauth2.credential=WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/
d2z2CGiw= adl://testhue.azuredatalakestore.net/some_folder/testfile
adl://testhue.azuredatalakestore.net/some_folder/wordcountout
```

To provide your ADLS credentials securely, see [Securely Providing ADLS Credentials](#) on page 4629.

3. Provide your application with file access.
4. For secure clusters, MapR-SASL (Simple Authentication and Security Layer), and Kerberos, import the required CA certificate.
 - [Open source documentation](#)
 - [Azure documentation](#)
 - [Azure documentation on authorization and access control](#)

Securely Providing ADLS Credentials

You can provide your ADLS credentials securely by hiding the open, readable configuration on the command line using the Hadoop credential provider.

Procedure

1. Generate a `jceks` file for ADLS authorization:

```
hadoop credential create dfs.adls.oauth2.client.id -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client ID
hadoop credential create dfs.adls.oauth2.credential -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client secret
hadoop credential create dfs.adls.oauth2.refresh.url -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value refresh URL
```

2. Run the `DistCp` example using the `jceks` file:

```
hadoop distcp
[-D hadoop.security.credential.provider.path=localjceks://hdfs/user/
USER_NAME/adlskeyfile.jceks]
hdfs://<NameNode Hostname>:9001/user/foo/007020615
adl://<Account Name>.azuredatalakestore.net/testDir/
```

3. Configure the `core-site.xml` file to use the `jceks` file:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://hdfs/user/USER_NAME/adlskeyfile.jceks</value>
  <description>Path to interrogate for protected credentials.</
description>
</property>
```

Using ADLS for Data Input or Output

You can use Azure Data Lake Store (ADLS) as a source or destination for your application data.

Prerequisites

For general information about the features of ADLS, refer to the [Azure Data Lake Store documentation](#).

For information about configuring ADLS as storage for a Hadoop cluster, refer to the official [Apache documentation](#).

The Azure Data Lake Storage access path syntax is:

```
adl://<Account Name>.azuredatalakestore.net/
```

You can use ADLS the same way as you use file system, substituting an `adl` scheme instead of `maprfs`, `hdfs`, `webhdfs`, and so on.

Procedure**1. Create a directory and read data:**

```
[mapr@node4 ~]$ hadoop fs -mkdir adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/

Found 1 items
drwxr-xr-x - 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:09
adl://<username>.azuredatalakestore.net/testdir
```

2. Put data into ADLS from your local file system:

```
[mapr@node4 ~]$ hadoop fs -put testfile adl://
<username>.azuredatalakestore.net/testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
testdir

Found 1 itemsrw-r-- 1 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:10
adl://<username>.azuredatalakestore.net/testdir/testfile
```

3. Delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

4. Run YARN jobs with your input and output stored in ADLS:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
adl://<username>.azuredatalakestore.net/testdir/testfile adl://
<username>.azuredatalakestore.net/wordcountout
```

Deleting Data from ADLS

You can delete your data from Azure Data Lake Store (ADLS).

Procedure

- To delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

Maven and the HPE Ezmeral Data Fabric

This section discusses topics associated with Maven and the HPE Ezmeral Data Fabric.

Maven Artifacts for the HPE Ezmeral Data Fabric

Maven artifacts can be used for dependency management when developing applications based on the the HPE Ezmeral Data Fabric.

You can access the data-fabric Maven repository by browsing [Nexus](#) or as follows:

```
<repositories>
  <repository>
    <id>mapr-releases</id>
    <url>https://repository.mapr.com/maven/</url>
    <snapshots><enabled>false</enabled></snapshots>
    <releases><enabled>true</enabled></releases>
  </repository>
</repositories>
```
